Very little free coke appears in the market. Market prices remain at the Government limits: Furnace, $6; 72-hour selected foundry, $7; crushed, over 1-in., $7.30, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended Apr. 27 at 343,865 tons, an increase of 6989 tons. Owing to incomplete returns shipments were not reported, except that river shipments were 17,620 tons, against 10,500 tons the preceding week.

Buffalo—The reports from the coke districts agree that it is difficult to get cars, especially for moving the coal from the mines to the ovens. So far as can be learned the furnaces in this district are getting coke enough to keep them running, but it is with much difficulty. Much doubt is expressed of the ability to do this were it not for the byproduct plants here, which not only provide the supply of their own concerns, but also sell considerable to the other furnaces, which are dependent on outside production. Prices are on Government basis, with $2 freight added.

Middle Western

GENERAL REVIEW

Shortage of equipment limits the storing of any great amount of coal regardless of the willingness of the public to put in large stocks.

Large storage orders have been placed with producing companies, but the limited car supply has prevented any great tonnage movement. At the solicitation of the Fuel Administration and operators the consumers have, in many instances, begun taking all the coal available, not only to provide sufficient fuel for immediate needs, but to make an earnest effort to create a surplus for future contingencies. So far the good intentions of consumers have not met with any measurable success, because of the failure of the railroads to provide a sufficient car supply. In few cases has the supply of cars been sufficient to give the mines more than 80 per cent. working time, and reports from some of the mines state they have not worked to 50 per cent. of capacity. During the past week the railroads have been buying considerable tonnage; in fact they have absorbed all the surplus sized coal, which has caused some worry with regard to finer grades. This is true in the Springfield and Fulton County districts, where there is a considerable amount of screenings unloaded at the mines. When the new zone plan went into effect there were some substantial contracts on screenings for movement to Kansas City, Mo. The cutting off of this market seriously affected the central Illinois fine coal market, as the movement had been of long standing, and necessitated the finding of another market.

Market conditions on high-grade Illinois and Indiana size coal are excellent, although some difficulty is reported in moving coal at the Government price from the inner-group territory.

The movement of anthracite into the Middle West has not anywhere come up to expectations, dealers claiming that this is due to the heavy eastern demand, which is having the first call.

CHICAGO

Railroad congestion continues to be embarrassing to the Chicago coal men.

The solution of the coal situation was again put up to the railroads this past week. The storage demand has suddenly become strong, and it is needless to say the mines will have all they can do provided they can at all times have a full car supply. While Chicago is a dumping-ground for anything that looks like coal, some grades of Illinois and Indiana have not brought the full Government price. Screenings have sold off 15c. per ton. This 15c. was given to the jobber, who in turn effected movement at the Government price. Friday and Saturday the market stiffened on fine coal and no off sales have been reported.

One of the gratifying results of the "buy your coal now" campaign is that users have fully satisfied themselves that it will be impossible to get eastern bituminous and that they must use either Illinois or Indiana; hence they are fast falling in line with their storage orders. Hard coal continues to move slowly, although there is some improvement over the previous week.

Quotations in the Chicago market are as follows, per net ton f.o.b. cars at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Springfield	Carterville	Grundy, La Salle, Bureau and Will

MILWAUKEE

Docks again busy receiving coal. Seventeen cargoes arrive in one week. Deliveries of the new supply of anthracite now being made. Hard coal to be 30c. lower than last season.

Lake traffic is in full swing again and coal cargoes are arriving daily, the first of the season having been received on Apr. 30. Up to and including May 6, 17 cargoes aggregating 130,747 tons, were docked. Of this amount 27,236 tons were hard coal. A more even flow of receipts is expected this season. Last year the movement was very irregular. Capt. W. C. Richardson, of Cleveland, a member of the mobilization committee, was on hand when the first cargo arrived. Because of the strike at the Escanaba ore docks, he ordered three vessels with capacity amounting to 27,700 tons, to proceed light to Lake Erie for coal.

Reports from 29 Wisconsin counties to the state fuel administration office are in effect that wood cutting is being prosecuted on a scale never before known, the increase ranging all the way from 25 to 400 per cent. Special Fuel Assistant Snead suggests that Milwaukee put in a supply to meet an emergency.

As a measure of conservation, Fuel Administrator Fitzgerald has issued an order limiting florists to 50 per cent. of their normal supply of coal. The business will be crippled, but the authorities hold that it is not necessary to the life and comfort of the American people.

The Wisconsin Railroad Commission has requested Federal Fuel Administrator Garfield to conduct a thorough examination into the cost of handling coal on the docks. The action was taken at the instance of Wisconsin public utility operators, following permission to them to increase their rates on account of the increased cost of coal.

The city fuel stations have been closed for the season. A total of 1,500,000 lb. or 825 tons, was sold at ½c. per pound. The matter of their reopening will depend upon circumstances.

ST. LOUIS

General conditions show considerable improvement and future prospects unusually good. Carterville is entirely oversold, and the market is beginning to tighten on everything excepting steam coal. Shortage of equipment continues and transportation is slow. Shortage of labor general. Small anthracite shipments and of poor quality.

The local situation is unusually good. Conditions in the past week have entirely changed, and it is almost impossible now to buy Carterville coal. The same may be said of DuQuoin coal. To begin with, there is a shortage of cars in the Carterville field, and the mines are not working regularly. Added to this is the fact that the tonnage of nearly all mines seems to be decreasing on account of labor shortage.

The general prosperity has brought about a desire on the part of the consumer to buy the best coal obtainable, with the result that the demand for Carterville is so far ahead of the available supply that nearly every mine in the Carterville field is sold up to the first of July, figuring on the present car supply.

In the DuQuoin field the car supply is short, and conditions are somewhat similar to those in the Carterville field. The Mt. Olive situation is fairly good. Car supply is better here than in the other fields, and the mines are working better time, with a better labor supply, although transportation is somewhat slow. This accounts in one way for the shortage of cars in the Carterville and DuQuoin field, inasmuch as the railroads are not moving some of their equipment as well now as they did under the adverse winter conditions. The demand for the Mt. Olive grade is exceptionally good locally.

In the Standard field the situation continues to improve, and while coal is being sold under the Government maximum price, indications are that this will not continue long. There have been instances in the past week where 2-in. lump has sold as low as $2.35 and 6-in. lump as low as $2.50. The car supply in this field on some roads is fairly good, but on the Illinois Central and Missouri & Ohio it is extremely bad.

The reconsigning restrictions also have a tendency to retard the equal distribution of coal, and this in itself has prevented a large tonnage of coal moving to places where it is needed.

The railroads have begun to buy. During the past week something like 1000 to 1500 cars of coal have been bought on the open market, with prices ranging from $2 to $2.15 for mine-run, depending on the period of shipment. They furnish their own cars.

The steam condition from all the fields is extremely poor. Carterville screenings are down to $2, and screenings from the DuQuoin field have gone as low as $1.75, while Standard screenings have been down to $1.40; and rumor has it that a lot of Standard screenings were sold in Chicago for the freight and demurrage.

There is little Arkansas coal coming in, and such small tonnage of anthracite as comes in from the east is off grade and off size and is not good coal.

While the market is off a little in a general way, quotations are the Government maximum, which is as follows:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.65@3.00	$2.65@2.80	$2.65@2.80

STRUCTURAL MATERIAL—The following are the base prices, f.o.b. mill, Pittsburgh, together with the quotations per 100 lb. from warehouses at the places named:

		—New York—			
	Mill, Pittsburgh	Current	1 Year Ago	St. Louis	Chicago
Beams, 3 to 15 in.	$3.00	$4.195	$4.75	$4.27	$4.20
Channels, 3 to 15 in.	3.00	4.195	4.75	4.27	4.20
Angles, 3 to 6 in., ¼ in. thick	3.00	4.195	4.75	4.27	4.20
Tees, 3 in. and larger	3.05	4.245	4.80	4.27	4.25
Plates	3.225	4.45	6.50	4.52	4.45

BAR IRON—Prices in cents per pound at cities named are as follows:

	Pittsburgh	St. Louis	Denver	Birmingham
Apr. 1, 1918	3.50	4.17	4.05	4.38

NAILS—Prices per keg from warehouse in cities named:

	Mill Pittsburgh	St. Louis	Denver	Chicago	Birmingham	San Francisco	Dallas
Wire	$3.50	$4.30	$4.85	$4.25	$4.25	$4.80	$4.75
Cut	3.75	5.25	.....	4.40	....	6.40	.....

TRACK SUPPLIES—The following prices are base per 100 lb. f.o.b. Pittsburgh for carload lots, together with the warehouse prices at the places named:

	Pittsburgh Current	Cincinnati	Chicago	St. Louis	San Francisco	Birmingham	Denver
Standard railroad spikes ⅝-in. and larger	$3.90	$6.00	$4.50	$5.30	$6.25	$5.30	$5.00
Track bolts	4.90	8.90	5.50	Pre-	7.45	6.75	6.00
Standard section angle bars	3.25	....	4.45	mium	4.90	....	4.30

COLD DRAWN STEEL SHAFTING—From warehouse to consumers requiring fair-sized lots, the following discounts hold:

Cincinnati	Cleveland	Chicago	St. Louis	Denver	Birmingham
17½%	List	+10%	+10%	+35%	+20%

HORSE AND MULE SHOES—Warehouse prices per 100 lb. in cities named:

	Mill Pittsburgh	Cincinnati	Chicago	St. Louis	Denver	Birmingham
Straight	$5.25	$6.50	$6.50	$6.25	$7.50	$6.50
Assorted	5.40	6.50	6.50–7.00	6.40	7.75	6.75

Cincinnati—Horseshoe nails sell for $4.50 to $5 per 25-lb. box

CAST-IRON PIPE—The following are prices per net ton for carload lots:

	—New York— Current	1-Month Ago	One Year Ago	Chicago	St. Louis	San Francisco	Dallas
4 in.	$58.35	$58.35	$58.00	$57.55	$57.00	$65.00	$61.00
6 in. and over	55.35	55.35	55.50	54.55	54.00	62.00	58.00

Gas pipe and 16-ft. lengths are $1 per ton extra.

STEEL RAILS—The following quotations are per ton f.o.b. Pittsburgh and Chicago for carload or larger lots. For less than carload lots 5c. per 100 lb. is charged extra:

	—Pittsburgh— Current	One Year Ago	—Chicago— Current	One Year Ago
Standard Bessemer rails	$65.00	$38.00	$65.00	$38.00
Standard openhearth rails	67.00	40.00	67.00	40.00
Light rails, 8 to 10 lb.	*3.135 (100 lb.)	58.00	*3.135 (100 lb.)	53.00
Light rails, 12 to 14 lb.	*3.09 (100 lb.)	57.00	*3.09 (100 lb.)	54.00
Light rails, 25 to 45 lb.	*3.00 (100 lb.)	53.00	*3.00 (100 lb.)	52.00

* Government price per 100 lb.

OLD MATERIAL—The prices following are per gross ton paid to dealers and producers in New York. In Chicago and St. Louis the quotations are per net ton and cover delivery at the buyer's works, including freight transfer charges:

	New York	Chicago	St. Louis
No. 1 railroad wrought	$31.50	$30.25	$35.00
Stove plate	25.00	22.25	20.00
No. 1 machinery cast	34.00	26.50	21.50
Machine shop turnings	15.25	15.50	20.00
Cast borings	15.25	15.25	19.00
Railroad malleable cast	34.00	27.00	25.50

COAL BIT STEEL—Warehouse price per pound is as follows:

New York	Cincinnati	Birmingham	St. Louis	Denver
$0.12	$0.16½	$0.18	$0.28	$0.17

DRILL STEEL—Warehouse price per pound:

	New York	St. Louis	Birmingham
Solid	15c.	14c.	15c.
Hollow	24c.	25c.	...

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh; basing card of Nov. 6, 1917, for steel pipe and for iron pipe:

BUTT WELD

Steel Inches	Black	Galvanized	Iron Inches	Black	Galvanized
⅛, ¼ and ⅜	44%	17%	¼ to 1½	33%	17%
½	48%	33⅓%			
¾ to 3	51%	37½%			

LAP WELD

2	44%	31½%	2	26%	12%

2½ to 4	45%	33½%	2½ to 4	29%	17%
4½ to 6	44%	32½%	4½ to 6	28%	16%

From warehouses at the places named the following discounts hold for steel pipe:

	—Black— New York	Chicago	St. Louis
⅜ to 3 in. butt welded	38%	42.8%	40.1%
3½ to 6 in. lap welded	18%	38.8%	36.1%
	—Galvanized— New York	Chicago	St. Louis
⅜ to 3 in. butt welded	22%	27.8%	25.1%
3½ to 6 in. butt welded	List	24.8%	22.1%

Malleable fittings. Class B and C, from New York stock sell at list price. Cast iron, standard sizes, 15 and 5%.

SHOP SUPPLIES

NUTS—From, warehouse at the places named, on fair sized orders, the following amount is deducted from list:

	—New York— Current	One Year Ago	—Cleveland— Current	One Year Ago	—Chicago— Current	One Year Ago
Hot pressed square	$1.05	List	$1.40	$1.90	$1.05	$3.00
Hot pressed hexagon	.85	List	1.20	1.70	.85	3.00
Cold punched square	1.00	List	75	1.40	1.00	2.50
Cold punched hexagon	1.00	List	75	1.40	1.00	3.00

Semifinished nuts sell at the following discounts from list price:

	Current	One Year Ago
New York	40%	50%
Chicago	50%	45%
Cleveland	60%	50%

MACHINE BOLTS—Warehouse discounts in the following cities:

	New York	Cleveland	Chicago
¾ by 4 in. and smaller	30—5%	40—10%	40—10%
Larger and longer up to 1 in. by 30 in.	30%	30—5%	35—5%

WASHERS—From warehouses at the places named the following amount is deducted from list price:

For wrought-iron washers:

New York..... $3.00 Cleveland..... $3.00 Chicago..... $3.00

For cast-iron washers the base price per 100 lb. is as follows:

New York..... $3.50 Cleveland..... $3.50 Chicago..... $3.50

RIVETS—The following quotations are allowed for fair-sized orders from warehouse:

	New York	Cleveland	Chicago
Steel ⅞ and smaller	30%	40%	40%*
Tinned	30%	40%	40%*

* For less than keg lots the discount is 35%.

Button heads, ¾, ⅞, 1 in. diameter by 2 in. to 5 in., sell as follows per 100 lb.:

New York..... $6.09½ Cleveland..... $5.85 Chicago..... $5.50

Coneheads, same sizes:

New York..... $6.19½ Cleveland..... $4.50 Chicago..... $5.60

MISCELLANEOUS

GREASES—Prices are as follows in the following cities in cents per pound for barrel lots:

	Cincinnati	Chicago	St. Louis	Birmingham	Denver	Pittsburgh
Cup	7	5¼	6.9	7½	10½	7½
Fiber or sponge	8	6	7.4	7½	15	7½

Gear	4½	4½	7.0	7½	6	3½
Car journal	22 (gal.)	3½	4.5	3	6	7½

BABBITT METAL—Warehouse prices in cents per pound:

	New York		Cleveland		Chicago	
	Current	One Year Ago	Current	One Year Ago	Current	One Year Ago
Best grade	90.00	65.00	100.00	65.75	100.00	60.00
Commercial	50.00	35.00	22.00	20.75	22.00	25.00

HOSE—Following are prices of various classes of hose:

Fire

	50-Ft. Lengths
Underwriters' 2½-in	75c. per ft.
Common, 2½-in	40%

Air

First Grade	Second Grade	Third Grade
¾-in. per ft $0.55	$0.30	$0.25

Steam—Discounts from list

First grade 30% Second grade 30–5% Third grade 40–10%

LEATHER BELTING—Present discounts from list in cities named:

	Medium Grade	Heavy Grade
St. Louis	40+5%	35%
Denver	35%	30%
Birmingham	35%	40%
Chicago	30—10%	40—5%
Cincinnati	40—10%	40%

RAWHIDE LACING—40% off list.

PACKING—Prices per pound:

Rubber and duck for low-pressure steam	$0.90
Asbestos for high-pressure steam	1.65
Duck and rubber for piston packing	1.00
Flax, regular	.90
Flax, waterproofed	1.10
Compressed asbestos sheet	1.00
Wire insertion asbestos sheet	1.20
Rubber sheet	.60
Rubber sheet, wire insertion	.90
Rubber sheet, duck insertion	.50
Rubber sheet, cloth insertion	.25
Asbestos packing, twisted or braided, and graphited, for valve stems and stuffing boxes	1.10
Asbestos wick, ¼- and 1-lb. balls	.65 to .70

WIRE ROPE—Discounts from list price on regular grades of bright and galvanized are as follows:

	New York and St. Louis
Galvanized iron rigging	+20% List
Galvanized cast steel rigging	30%
Bright plain rigging	17½%
Bright cast steel	5%
Bright iron and iron tiller	

MANILA ROPE—For rope smaller than ⅝-in. the price is ½ to 2c. extra; while for quantities amounting to less than 600 ft. there is an extra charge of 1c. The number of feet per pound for the various sizes is as follows: ⅝-in., 8 ft.; ¾-in., 6; ⅞-in., 4½; 1 in., 3½; 1⅛-in., 2 ft. 10 in.; 1¼-in., 2 ft. 4 in. Following is price per pound for ⅝-in. and larger, in 1200-ft. coils:

Boston	$0 34½	Atlanta	$0.36
New York	33¼	Denver	35½
Cincinnati	33½	Kansas City	34
Chicago	32½	New Orleans	33
St. Paul	34	Seattle	33½
San Francisco	31	St. Louis	33
Pittsburgh	36	Los Angeles	32

PIPE AND BOILER COVERING—Below are discounts and part of standard lists:

PIPE COVERING		BLOCKS AND SHEETS	
Pipe Size	Standard List Per Lin. Ft.	Thickness	Price per Sq.Ft.
1-in.	$0.27	½-in.	$0.27
2-in.	.36	1-in.	.30
6-in.	.80	1½-in.	.45
4-in.	.60	2-in.	.60
3-in.	.45	2½-in.	.75
8-in.	1.10	3-in.	.90
10-in.	1.30	3½-in.	1.05

85% magnesia high pressure 15% off

For low-pressure heating and return lines: 4-ply 58% off; 3-ply 60% off; 2-ply 62% off

LINSEED OIL—These prices are per gallon:

	New York		Cleveland		Chicago

5-lb. cans	11.82½	15.25	13.25	13.50	11.82½	13.00
1-lb. cans	13.72½	14.62½	13.25	13.50	13.72½	13.00

COMMON BRICK—The prices per 1000 in cargo or carload lots are as follows:

Cincinnati	$12.00	Birmingham	$15.00
St. Louis, salmon	9.00	Denver	8.50

WIRING SUPPLIES—New York prices for tape and solder are as follows:

Friction tape, ½ lb. rolls	35c. per lb.
Rubber tape, ½-lb. rolls	45c. per lb.
Wire solder, 50-lb. pools	45c. per lb.
Soldering paste, 1-lb. cans	50c. per lb

PREPARED ROOFINGS—Standard grade rubbered surface, complete with nails and cement, costs per square as follows in New York, St. Louis Chicago and San Francisco.

	1-Ply		2-Ply		3-Ply	
	C.l.	L. C.l.	C.l.	L.C.l.	C.l.	L.Cl
No. 1 grade	$1.30	$1.55	$1.60	$1.75	$1.90	$2.05
No. 2 grade	1.15	1.30	1.45	1.60	1.75	1.90

Asbestos asphalt saturated felt (14 lb. per square) costs $5.35 per 100 lb.

Slate-surfaced roofing (red and green) in rolls of 108 sq.ft. costs $1.95 per roll in carload lots and $2.20 for smaller quantities.

Shingles, red and green slate finish cost $5.25 per square in carloads, $5.50 in smaller quantities, in Philadelphia.

ROOFING MATERIALS—Prices per ton f.o.b. New York or Chicago:

	Carload Lots	Less than Carload Lots
Tarfelt (14 lb. per square of 100 sq. ft.)	64	65
Tar pitch (in 400-lb. bbl.)	20	21
Asphalt pitch (in barrels)	35	40
Asphalt felt	72.50	77.50

STEEL SHEET PILING—The following price is base per 100 lb. f.o.b. Pittsburgh, with a comparison of a month and a year ago:

Current	One Month Ago	One Year Ago
4–5	$3.10	$3.10

HOLLOW TILE—The price per 1000 in carload lots f.o.b. mine is as follows:

	4 x 12 x 12	8 x 12 x 12
St. Louis	$80.00	$137.00
Chicago	79.00	137.00
Denver, per ton	11.00	200.00
Kansas City	75.00	140.00
St. Paul	56.00	110.00
Boston	80.00	150.00
Birmingham	61.20	114.80
Cincinnati	68.80	129.00
Pittsburgh	86.50	147.10

LUMBER—Price of yellow pine per M in carload lots:

	1-in. Rough 10 In. x 16 Ft.	2-In. T. and G. 10 In. x 16 Ft.	8 x 8 In. x 20 Ft.

COAL AGE

Volume 13 NEW YORK, MAY 18, 1918 Number 20

The Lesson

Written expressly for Coal Age

BY BERTON BRALEY

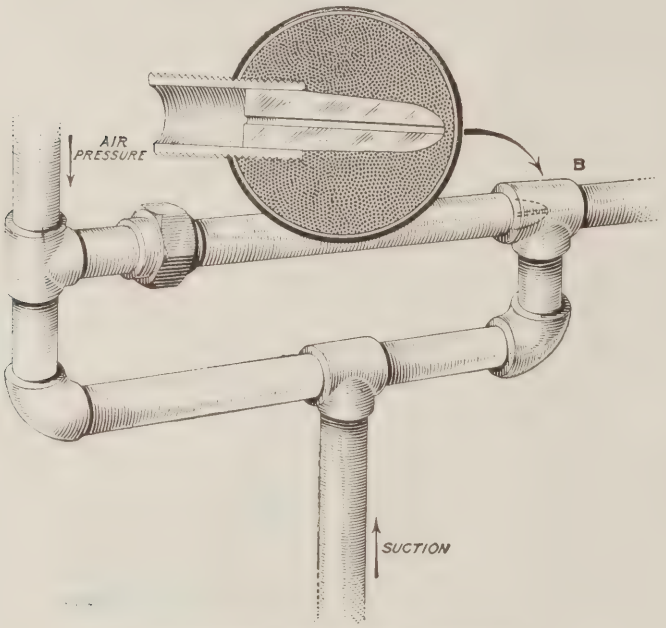
There is no "Private Business" any more,
No trade that we can manage as we choose,
For in the mighty holocaust of war
The Nation's need comes first, and we must lose
Our petty pride in personal success
And merge ourselves in one tremendous whole,
Break from the fetters of our selfishness
And help our land to win the war with coal.

There is no "Private Business" any more,
That is a fact which we must recognize,
The interests that we have served of yore
Are lost in this titanic enterprise;
Nothing we own is ours, but held in trust
To serve the Nation in its greater need,
The individual is less than dust,
"All for our country" is the business creed.

Annihilate the Hun

Brushed Aside

There is no "Private Business" any more,
No man may say: "This enterprise is mine,
Which I shall manage, as I have before,
According to the plans that I design";
That old conception has been brushed aside
By vast events and we have come to know
That if the things we care for shall abide
Our little private interests must go.



Tipple and breaker, gallery and seam,
No longer are they ours; they help to make
The strength of that huge economic scheme
Which backs our men who fight for freedom's sake.
We've yielded much of "vested rights" and power—
We shall yield further at the call of war;
Our selfish plans are nothing at this hour,
There is no "Private Business" any more.

IDEAS AND SUGGESTIONS

A Duplex Ejector

BY L. V. LAUTHER
Guttenberg, N. J.

Most men about coal mines are familiar with the ordinary type of homemade ejector composed essentially of a tee with a suitable nozzle screwed into one run opening, the discharge screwed into the other while

COMPOUND HOMEMADE EJECTOR

the outlet opening receives the suction. This type of ejector while fairly successful for low heads is not powerful. The accompanying illustration shows what might be termed a "duplex" ejector. While it is somewhat more elaborate than the "simplex" ejector it is also more powerful. The construction is simple and needs no comment. For 1-in. pipe and fittings the nozzle opening should be about $\frac{5}{16}$ in. in diameter.

How Soon Will Heat-Insulating Material Pay for Itself?

BY W. F. SCHAPHORST
New York City

The caption states a problem that should certainly interest the owner, superintendent, engineer and everybody else connected with the economic problems that must daily be met in and about a power plant. At first blush it may seem like a rather indeterminate problem, but elaborate tests have been made on the subject of heat transmission through bare pipes, and on these I have built a formula giving the cost of the heat loss in any number of hours. By reversing the formula it is possible to compute the number of hours required for a given heat-insulating material to pay for itself.

The formula is as follows:

$$H = \frac{2000PBE_b}{(1.6 + 0.0056D)DACE_c}$$

where

H = Number of hours required for the covering to pay for itself;
P = Cost of pipe covering per lineal foot;
B = B.t.u. per pound of coal;
E_b = Efficiency of the boiler;
D = Temperature difference in deg. F., or the metal temperature minus the room temperature;
A = Area of the metallic surface in square feet;
C = Cost of coal per ton of 2000 lb. in dollars;
E_c = Efficiency of the covering.

It is quite possible that this formula will give rather surprising results in a good many cases. The opinion of many is that a covering will pay for itself in a short time. They over-estimate the value of pipe covering and heat insulation in general, because the value of coverings is a subject that has been harped on for many years. Others have a tendency to sneer at coverings, claiming that prices are so high that they never pay for themselves. However, let us take an example and by means of this formula see for ourselves. Let us take a case where

P = $2 per lineal foot;
B = 12,000;
E_b = 70 per cent.;
D = 200;
A = 3.1416 sq.ft., or the area of a pipe 1 ft. in diameter and 1 ft. long;
C = $4;
E_c = 90 per cent.

Substituting in the formula we get

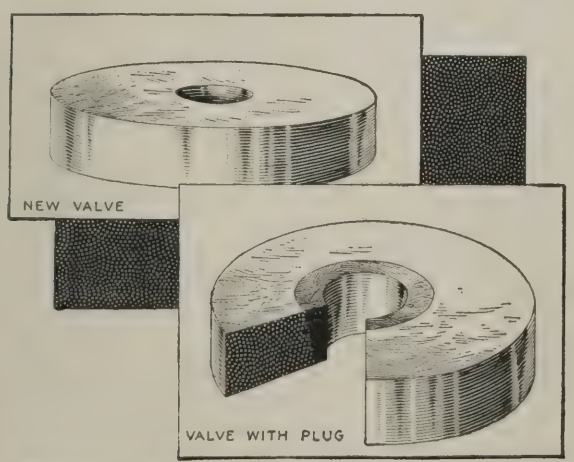
$$H = \frac{2000 \times 2 \times 12{,}000 \times 0.70}{[1.6 + (0.0056 \times 200)]200 \times 3.1416 \times 4 \times 0.90} = 5480\ hr.$$

which is equivalent to about 228 days, assuming that the pipe was under steam continuously, day and night. If the steam periods are intermittent (as is often the case in heating systems) the number of days, of course, will be greater. Thus in some heating systems where the pipes are under pressure for approximately 100 days per year it will take a trifle over two years for the covering to pay for itself. But insulating materials are durable. In fact, there is no reason why they should ever wear out under proper care, especially indoors. Therefore, after one or two years of use the steam saved is "pure profit."

This formula is applicable to flat or round surfaces. A good way in which to use the formula, therefore, is to compute the cost of the covering per square foot and in the formula insert "one square foot" for A. The relative values of the various sizes of coverings will thus easily be solved. Small pipe coverings usually cost more per square foot of surface covered and there-

fore it will take longer for the covering to pay for itself. This leads to the conclusion that large pipes, certainly, should be insulated against heat loss.

It will be readily understood that a formula of this kind cannot apply equally well indoors and out. The temperature difference is generally much greater out-of-doors, and the radiating effect is also greater on account of the more serious nature of the air currents. A wintry blast against a hot steam pipe is notorious as a money waster. I therefore wish to impress upon the minds of readers that in applying this formula to out-of-door conditions it can be correctly assumed that the coverings will pay for themselves much more quickly than the result will indicate. The greater the temperature difference and the more rapid the air currents the more necessary the insulation.



The formula also shows that a high boiler efficiency will increase the number of hours (H), whereas a high efficiency of the covering will decrease the number of hours. It furthermore shows, of course, that a good inexpensive covering is most desirable. It is probably true, in extreme cases, that covering doesn't pay; but by applying this formula carefully it is my belief that such cases will seldom be found.

Keeping Rubber Valves in Service

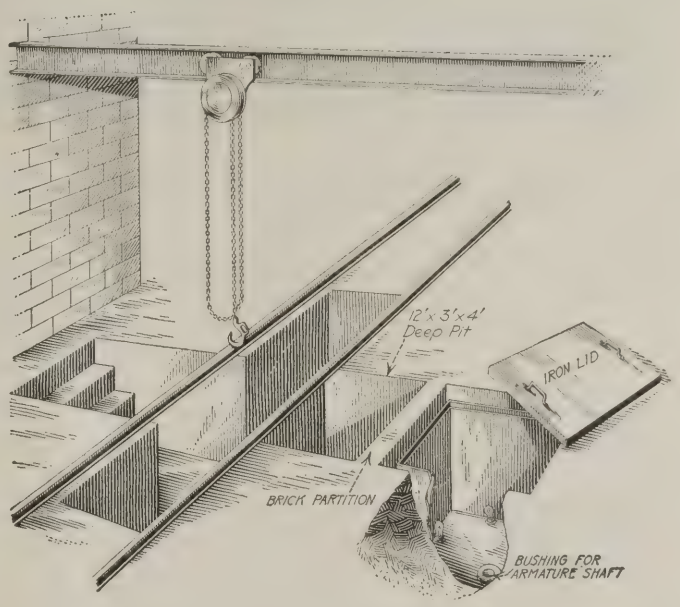
By Timothy Ryan
Hazleton, Penn.

The following is a method whereby increased service can be secured from rubber pump valves. I have had considerable trouble with valves of this kind and they became an expensive item of repairs.

The hole in the valve becomes enlarged, due to the friction of the valve stem, and practically new valves would have to be cast aside as the hole in the center would allow too much water to pass through it. I have overcome this difficulty with a rubber bushing. To do this I take a valve with a large hole and punch the hole somewhat larger; then take an old valve that is of no use and punch a piece from it to fit the hole in the valve

METHOD OF REPAIRING WORN RUBBER VALVES

to be used again. This makes a blank valve. The hole in the center can now be made of a size to fit the valve stem. Before placing the enlarged plug in the valve, I, of course, apply a little rubber cement.



When the hole in the center of a bushed valve becomes too large, the center can be replaced by another bushing with a smaller hole.

By this means valve stems that are worn small can be kept in service. Thus if the original size of the stem was $\frac{3}{4}$ in. and it wears down to say, $\frac{5}{8}$ in., the stem hole in the center of the valve can be punched $\frac{5}{8}$ in. I have tried this method for several months and find it works quite satisfactorily.

Homemade Armature Oven

By R. Z. Virgin
Wheeling, W. Va.

At the ordinary mine plant there is no oven built or provided wherein the electrician may bake the armatures after winding. A homemade oven, similar to the one shown in the accompanying illustration, may be used

REPAIR PIT AND ARMATURE OVEN

for this purpose; while the idea is not new, it perhaps has not been thought of in some localities.

Above is shown the side wall of the building, with an "I" beam across the motor pit, on which runs a trolley carrying a set of chain blocks which are used to lift wheels, armatures, etc. At one side the pit is extended and partitioned off with brick or cement. This portion of the extension is of noncombustible material and is 48 in. long, 48 in. wide and 40 in. deep. Into this fits a box 30 x 36 in. and 36 in. deep, lined with sheet asbestos $\frac{1}{8}$ in. thick. Inside the box are placed eight carbon lamps, 16-cp., 250 volts. In the bottom of the box is a bushing or step bearing long enough to accommodate the armature shaft and take its weight. This keeps the armature upright.

After the armature is wound, it is taped on the ends to keep the varnish off, and submerged in a tank of baking varnish, just up to the commutator. It is then drained off and allowed to stand and drain for 24 hours, after which it is placed in the oven and baked for 36 to 48 hours. If a second coat is desired the same process is repeated. A box of this size will accommodate armatures of about the size generally used in a 15-ton locomotive.

Bettering Coal by Heat and Pressure*

By CHARLES T. MALCOLMSON
President, Malcomson Briquet Engineering Co., Old Colony Building, Chicago, Ill.

SYNOPSIS — *The coal is distilled at a low temperature. The semicoke thus obtained is mixed with pitch obtained from that distillation. It is then briquetted and subjected to a further distillation at 1800 deg. F. More tar, oils and ammonium sulphate are obtained than when coking coal in the byproduct coke oven.*

AN ELABORATE series of experiments has been conducted during the past three years at Irvington, N. J., which has resulted in the perfecting of a process for the manufacture of smokeless fuel from high-volatile coals, and for the recovery and refinement of the coal-tar products derived therefrom. These experiments have been financed by Blair & Co., of New York, and were conducted under the direction of Charles H. Smith, the inventor of the process.

The low-temperature distillation of coal has interested investigators for many years. Sporadic attempts have been made to solve the mechanical problems, but until the Smith process was developed they were not carried to conclusions of economic value. The present coal shortage and the increasing demand for smokeless fuels make this subject one of timely interest.

Description of Plant

The following equipment was installed and operated during the experimental period: Four horizontal and two vertical units of commercial size for the low-temperature distillation of the coal; two vertical, two horizontal and two inclined benches for distillation of the briquets at medium and higher temperatures; presses and auxiliary equipment necessary for making briquets; and a complete byproduct recovery and tar-refining plant. This commercial equipment is provided with gas and electric meters, pyrometers and other apparatus for recording accurately the results of all experiments.

There is, in addition to the commercial equipment, a complete chemical laboratory with distillation and recovery apparatus, including facilities for refining and cracking the tar and measuring the yields and calorific value of the gas. This apparatus makes it possible to study on a small scale the various problems involved in the process.

Description of Process

Mr. Smith's experiments have resulted in the production on a commercial scale of: (1) A fuel, called "carbocoal," which, for convenience in handling, is prepared in briquet form. (2) A yield of tar more than double that obtained in the ordinary byproduct coking process. (3) Ammonium sulphate in excess of that normally recovered in the ordinary byproduct coking process. (4) Gas, in amount approximately 9000 cu. ft. per ton of coal carbonized, which is at present used in the process.

The essential features of the Smith process are the two distillations carried on at different temperatures, first of the raw coal and second of the raw briquets. The raw coal, after being crushed, is distilled at a relatively low temperature, 850 to 900 deg. F., and the volatile contents are thereby reduced to the desired point. The result of this first distillation is a large yield of gas and tar, and a product rich in carbon, termed "semi-carbocoal." The semi-carbocoal is next mixed with a certain proportion of pitch obtained from the tar produced in the process, and this mixture is

*Paper entitled "Carbocoal," to be read at the Colorado meeting of the American Institute of Mining Engineers, September, 1918.

briquetted. The briquets are then subjected to an additional distillation at a higher temperature, approximately 1800 deg. F., resulting in the production of carbocoal, the recovery of additional tar and gas, and a substantial yield of ammonium sulphate.

The characteristic feature of the primary distillation is that it is continuous and that the coal is constantly agitated and mixed during the entire operation. This is accomplished by a twin set of paddles which also advance the charge through the retort. By this means, all portions of the charge are uniformly distilled, and by controlling the speed at which the charge moves through the retort the distillation may be arrested at any desired stage. As only a partial carbonization is permitted in the primary distillation, the hard metallic cells characteristic of coke are avoided. The period of distillation is one to two hours, and the continuous retort has a carbonizing capacity of one ton of coal per hour.

In the subsequent distillation of the briquets, all evidence of the pitch as a separate ingredient disappears. There is a marked shrinkage in the volume of the briquet, with a corresponding increase in density, but no distortion of its shape. This distillation requires four to five hours and is performed in an inclined, self-charging and self-discharging bench.

The carbocoal represents more than 72 per cent. of the weight of the raw coal, the exact percentage depending upon the volatile content of the latter.

Carbocoal is dense, dustless, clean, uniform in size and quality, and can be readily handled and transported long distances without disintegration. It is grayish black in color, slightly resembling coke, but its density more nearly approaches that of anthracite coal. It is manufactured in briquet form and can be made in any

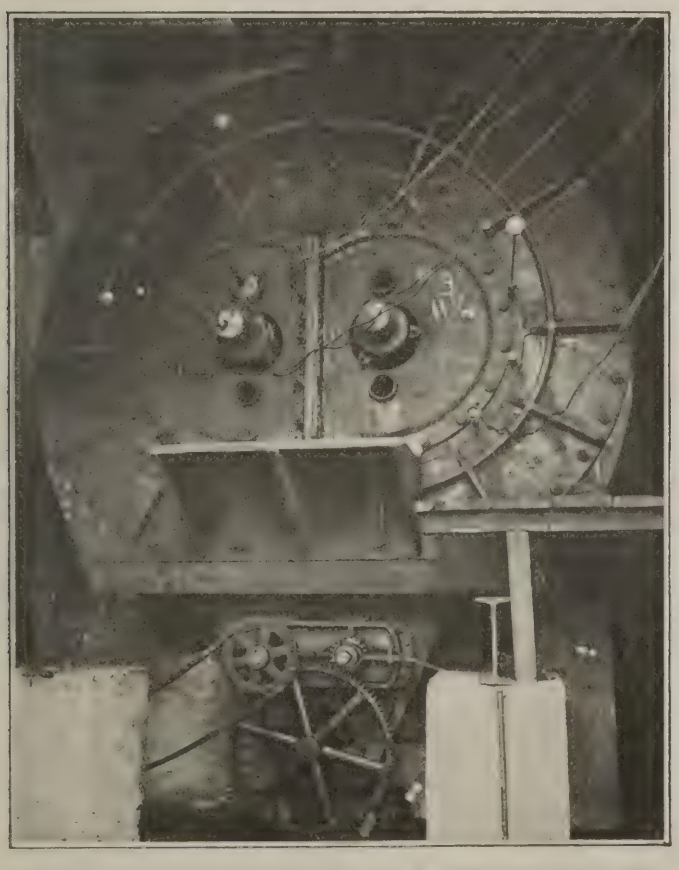


FIG. 1. DISCHARGING END OF A PRIMARY RETORT

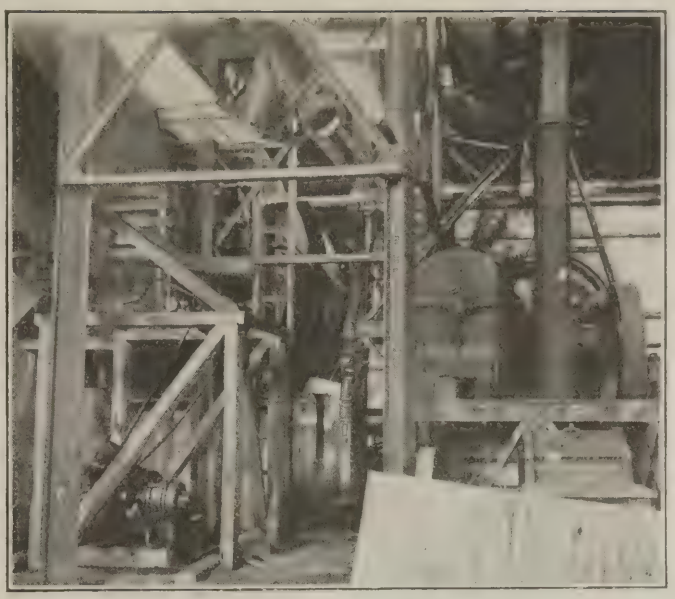

FIG. 2. WHERE COAL IS CHARGED TO PRIMARY RETORTS

size, from $\frac{1}{2}$ oz. to 5 oz. The larger sizes are better suited to locomotive purposes, and the smaller sizes for domestic use.

Heretofore, devolatilized fuels, such as coke, have not attained the high rates of combustion desired for locomotive, marine and general steam purposes; and their greater displacement has operated against their general use where transportation cost or stowage space has been an important factor. Carbocoal overcomes these objections. It is actually a relative soft but tough form of carbon, readily attacked by oxygen in combustion; and for this reason, requires much less draft than other high-carbon fuel.

Carbocoal has been tested by the Long Island R.R.; by the Pennsylvania R.R. at its testing plant at Altoona; by the Carolina, Clinchfield & Ohio R.R.; and by the United States Navy.

These tests have demonstrated that the fuel is smokeless. At a combustion rate of 100 lb. per hour on each square foot of grate surface it has evaporated 8.5 lb. of water, from and at 212 deg. F., per pound of fuel fired. At the lower combustion rate of 27 lb. per hour on each square foot of grate surface it has evaporated 12.8 lb. of water, from and at 212 deg. F., per pound of fuel fired. It has been demonstrated also that it requires no greater draft than bituminous coal. A maximum combustion rate of 166 lb. per hour on each square foot of grate surface has been reached for a short period.

Carbocoal has been found particularly suitable for the following purposes: (1) Marine and locomotive service, where limited grate area and restricted boiler capacity demand efficient fuel; where smoke is objectionable or dangerous, as in the case of ships in time of war. (2) Stationary boilers, where smoke pollution of the air is offensive and dangerous to health. (3) Domestic uses, including furnaces, stoves, ranges and open grates, where cleanliness is a desirable factor. (4) Kilns, drying and roasting ovens, and all purposes where an intense and uniform heat is desired. (5) In metallurgical furnaces, as a substitute for coke. (6) Gas producers.

Carbocoal has been subjected to practical tests in

household use for over a year. It fulfills all the requirements of a domestic fuel. It can be burned satisfactorily without change of furnace or grates, and it responds readily to changes in draft. The uniformity of combustion, absence of fines, even distribution of ash, and absence of clinker as compared with the coal from

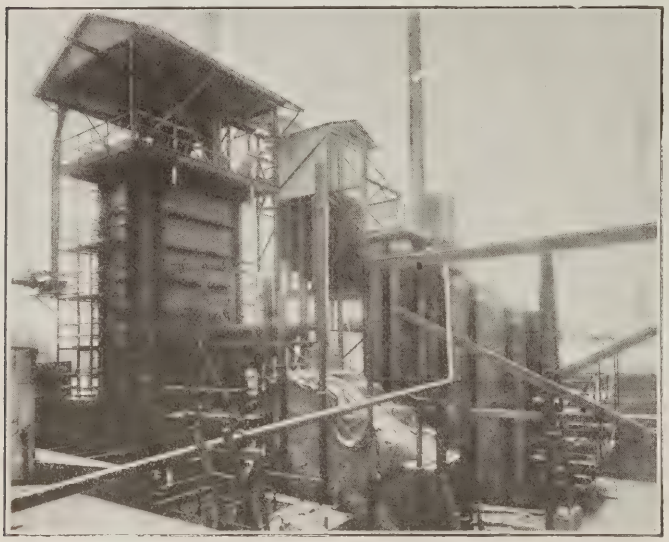

FIG. 3. INCLINED BENCHES FOR CARBONIZED BRIQUETS, KNOWN AS SECONDARY RETORTS

which it is made, are additional characteristics in favor of this fuel. Tests have demonstrated that carbocoal can be banked satisfactorily overnight, requiring no more attention, and with no greater consumption, than anthracite.

Carbocoal is compressed into briquet form to obtain maximum density, to minimize transportation costs and the losses incident to handling; and to secure the efficiency of combustion resulting from uniformity of size. Briquets of bituminous and anthracite coals have been manufactured for many years. Such briquets are made from the smaller sizes or screenings of coal, with the addition of a binder, such as coal-tar pitch. In carbocoal, however, an entirely new product is obtained, differing from the original coal in chemical and physical properties. The briquets contain no binding material to soften or disintegrate in the fire. Carbocoal must therefore be recognized not as a mixture, but as a new product, the result of a process of manufacture.

The amount of ash and sulphur in the carbocoal depends upon the characteristics of the coal from which it is made. The summarized proximate analyses of carbocoal, manufactured from 25 different coals at the Irvington plant, are shown in Table I.

The percentage of byproducts recovered from clean coal is greater than that recovered from high-ash coals; therefore the careful preparation of the raw coal by washing or other means is profitable.

TABLE I. ANALYSES OF CARBOCOAL

	From Run-of-Mine, Per Cent.	From Washed Coal, Per Cent.
Moisture	1.00 to 3.00	1.00 to 3.00
Volatile matter	0.75 to 3.50	0.75 to 3.50
Fixed carbon	82.00 to 88.00	85.00 to 90.00
Ash	8.50 to 12.00	7.00 to 10.00
Sulphur	0.5 to 1.50	0.6 to 1.50

The total yield of tar by the carbocoal process is large. Coal containing 35 per cent. volatile combustible produces more than 30 gal. of water-free tar per short ton. The tar products recovered from the distillation of the coal, at the low temperature used in this process, are different in nature from those obtained in other processes where high temperatures are used. At the lower temperature, there is an abundance of tar vapors and a relatively small yield of gas of high illuminating value. At the higher temperature these primary products are split up, with a consequent increase in the gas yield and a corresponding decrease in its illuminating value and in the amount of tar vapors recovered. There is also an increase in the percentage of residuals, the pitch increasing from 30 per cent. in the low-temperature distillation, to 64 per cent. or more when high temperatures are used.

The tar obtained in the primary distillation of the coal has a specific gravity of 1.00 to 1.06. It contains a large percentage of light solvent oils, tar acids and cresols, but very little carbolic acid and no naphthalene or anthracene. The free-carbon content of this tar is low. The light oils contain appreciable quantities of naphthenes, pentane, hexane, hexahydro-benzenes, and also hydrocarbons of the paraffin series, which make these oils valuable as a substitute for gasoline.

A satisfactory method of removing the paraffin and aromatic portions of the light oil has been developed, so that chemically pure (or rather c. p.) benzol and toluol can now be obtained by this process. During the low-temperature distillation period, 20 to 28 gal. of tar, including the light oil obtained from the stripping of the gas, are recovered, the exact amount depending upon the volatile content of the coal. This low-temperature tar contains approximately 30 per cent. of pitch and 70 per cent. of tar oils, as compared with 50 to 60 per cent. of pitch and 40 to 50 per cent. of oil products contained in ordinary gas-house and coke-oven tar. In the second or high-temperature distillation, 5 to 6 gal. of tar are added to the above yield. This tar is heavier than that obtained from the first distillation, and is similar to coke-oven tar.

Table II compares the tars and light oils obtained in the production of carbocoal with those obtained in the

FIG. 4. RAW BRIQUETS MADE FROM SEMI-CARBOCOAL

ordinary byproduct coking processes. In addition to the above yield of tar there is obtained, in both the byproduct coke oven and the carbocoal process, by stripping the gas, from 2 to 3 gal. of light oil. This yield depends upon the characteristics of the coal carbonized. Approximately 30 per cent. of the fraction from 170

to 360 deg. F. in the carbocoal process are tar acids; the remainder of the fractions are neutral oils. The value of the products from the distillation of tar depends, of course, on the extent to which the tar is refined. The fractionation and subsequent treatment of the tar oils, which is a part of this process, give the products shown in Table III, for the carbonizing of 1000 tons of coal; the figures are based upon data obtained from carbonizing run-of-mine coal from Clinchfield, Virginia.

TABLE II. RECOVERY OF LIQUID PRODUCTS PER TON OF RAW COAL CARBONIZED

	Distillation Temperature, Deg. F.	By-product Gal.	Coke Oven Per Cent.	Carbocoal, First Distillation Gal.	Carbocoal, First Distillation Per Cent.	Carbocoal, Second Distillation Gal.	Carbocoal, Second Distillation Per Cent.
Light oil	0–170	0.27	3.47	1.58	6.60	0.003	0.05
Middle oil	170–230	0.44	5.85	3.29	13.70	0.036	0.60
Creosote oil	230–270	0.78	10.37	3.11	12.95	0.126	2.10
Heavy oil	270–360	1.26	16.81	8.88	37.00	2.485	41.42
Pitch		4.66	62.18	6.90	28.75	3.290	54.83
Loss		0.09	1.32	0.24	1.00	0.060	1.00
Totals		7.50	100.00	24.00	100.00	6.000	100.00

Pitch is always an element of questionable value in tar distillation. The Smith process, however, utilizes all of its pitch for briquetting the semi-carbocoal produced by the first distillation. Moreover, the valuable portions of this pitch are recovered in the tar and gas resulting from the second distillation. It is therefore noteworthy that all the tar products recovered by this process are oil derivatives.

TABLE III. PRODUCTS OBTAINED FROM A THOUSAND TONS OF CLINCHFIELD, VA., COAL

	Raw Coal	Carbocoal	
1. Carbocoal of analysis hereinunder			725 tons
Moisture	0.72	1.84	
Volatile matter	35.01	2.75	
Fixed carbon	57.23	85.64	
Ash	7.04	9.77	
	100.00	100.00	
Sulphur	0.63	0.52	
2. Sulphate of ammonia			20,000 to 25,000 lb.
3. Other nitrogen products, principally, pyridine bases, approximately			2,000 to 4,000 oz.
4. Motor spirits (or c. p. benzol, 250 gal., c. p. toluol, 500 gal., motor spirits, 1,000 gal.)			1,800 to 2,200 gal.
5. Crude tar, acids principally cresylic acids			4,040 gal.
6. Water-white naphthas			3,500 gal.
7. Creosote oil			5,450 gal.
8. Heavy creosote oil			4,660 gal.
Other products, used in process:			
9. Pitch			10,000 gal.
10. Gas, of 530 B.t.u., approximately			9,000,000 cu.ft.

The primary distillation of the raw coal gives only a small yield of ammonium sulphate. The secondary distillation of the raw briquets, however, brings the amount up to approximately 21 lb. per short ton of raw coal carbonized.

In the primary distillation of the raw coal, from 5000 to 6000 cu.ft. of gas per short ton of coal is recovered. This has a heating value of 650 to 700 B.t.u. per cubic foot. The distillation of the briquets yields also about 4000 cu.ft. of gas of 350 to 400 B.t.u. per cubic foot. The process in its present stage of development uses all of the gas recovered from both distillations.

The illustration at the head of the article shows the carbonized briquets that are known as carbocoal.

Two of the most important conditions that make mechanical stokers successful in burning smoky coal without smoke probably are: (a) Slow and uniform heating of the coal with the result that a large part of the volatile matter is distilled at low temperature, and (b) distillation of the volatile matter occurs in the presence of oxygen.—*Bureau of Mines Bulletin No. 135.*

Prevention of Mine Explosions

By James Ashworth
Consulting Mining Engineer, Vancouver, B. C., Canada.

The following brief notes from the recent address of the president of the Monmouthshire District Association of Students in England, will be of interest in connection with the unsolved problem of preventing disastrous explosions of gas and dust in coal mines:

The disaster at Halmerend, North Staffordshire, is another tragic lesson to us that, in spite of all that has been done, we have yet no right to suppose that we have secured immunity from explosions.

Watering and stone-dusting may be made an effectual defence against the initiation and propagation of explosions in main roadways if the watering is continuous; or if steps are taken to insure that the stone dust is regularly applied and intimately mixed with the coal dust.

It is essential that the walls and roof should present a smooth surface, without projections or cavities in which coal dust and gas may lodge. But even when the roadways are rendered safe, there still remains the question of preventing explosions at the coal face. Here watering cannot be satisfactorily applied, and the coal dust is formed in such enormous quantities, and with such rapidity that effective stone-dusting may be generally considered to be impracticable. It is therefore worth considering, whether some totally new method cannot be discovered whereby the danger from coal dust may be entirely eliminated. . . .

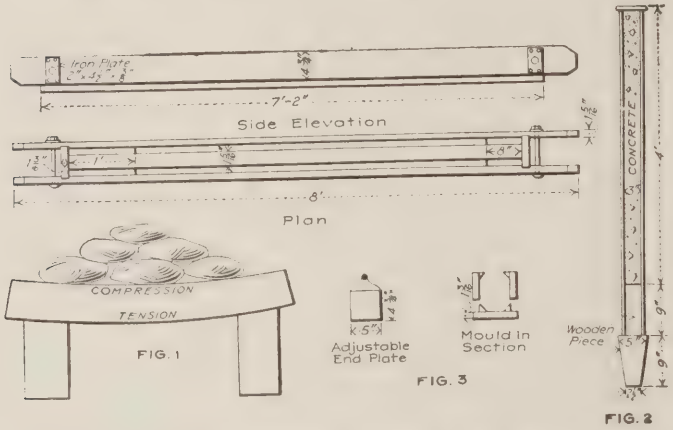
Safety Lamps—It would be well worth while trying to discover some sure and rapid method of detecting and estimating firedamp without the use of flame of any kind. This would permit of electric safety lamps, only, being used in the mine and would be another great step taken on the way to safety.

Rescue Apparatus—Here, there is also need of improvement. A short while ago Dr. Haldane made the startling and distressing statement that most forms of apparatus in use were little better than death traps. After a time, the oxygen in the breathing bag may reach a high temperature; and this, together with the weight of the apparatus, may be sufficient to produce exhaustion and collapse on the part of the rescuer, even in circumstances where without the apparatus the man would be safe.

Messrs. Corrie and Winborn, at the request of the Commission on Breathing Apparatus, have recently been investigating this point, and have found that, by introducing a quantity of sodium sulphate crystals into the breathing bag, the temperature may be kept sufficiently low to permit the rescuer to work without discomfort.

Sodium sulphate melts at a temperature of 34 deg. C., and, on melting, extracts its latent heat of fusion from the oxygen and thereby keeps the temperature in the bag low, which is a most interesting direct and simple application of pure science to a practical problem.

These subjects offer quite a large field for discussion and investigation. There are many weak points in the different types of mining equipment in use today, and these require constant study to ascertain if possible how to improve them.



Concrete in Coal Mine Service

By J. F. SPRINGER
New York City

SYNOPSIS — *Concrete is being used more and more about mines, replacing less permanent construction materials. Unfortunately concrete possesses low tensile strength. This may in part be rectified by suitable reinforcement. In order to be dense and strong sufficient sand only should be used in concrete to fill the voids in the crushed rock or gravel; enough cement should be used to fill the voids in the sand.*

IT WILL be wise for coal-mine officials having little or no knowledge of concrete to familiarize themselves with its qualities in advance of committing themselves to its use. They will then be better able to see exactly where it can be used to advantage and where its use would probably lead to disappointment.

Concrete is a splendid material in its proper place. There are many ways in which coal mines may employ

FIGS. 1 TO 3. CONCRETE BEAM, MINE PROP AND DETAILS OF WOODEN FORM

it with economy and satisfaction. Some of these are now being taken advantage of while others are being developed. Other uses await discovery through the inventive and adaptive ability of coal-mine officials. It is so important, however, to have a just conception of the character of concrete that no apology or further explanation will perhaps be necessary to justify a brief statement of its qualities.

Concrete is strong in compression. That is, it will endure heavy pressure tending to squeeze its mass together. But it is weak in tension. It is therefore ill-adapted to resist stresses tending to pull its particles apart.

There is, however, a corrective for this weakness. Steel possesses in high degree the quality lacked by concrete. Furthermore, its coefficient of linear expansion is nearly the same as that of concrete. Steel may be regarded as having a coefficient of 0.0000066 for each degree Fahrenheit. Concrete has a coefficient of 0.0000055. This fact makes it possible to employ this metal to supply what concrete lacks. That is to say, properly reinforced concrete possesses considerable tensile strength. Naturally, however, such concrete is more expensive than that made without reinforcement. While ultimately highly rigid, concrete may be molded or cast in a great variety of sizes and forms. This constitutes a great advantage over other masonry and is one of the chief reasons for the tremendous popularity of this material with construction engineers. This quality ought to recommend it for mine use.

Concrete is highly indestructible. It cannot be said that no fire, however hot, will break it down; but it is one of the most highly fire resistant materials in use for construction purposes and a favorite with fire insurance companies. It is also age-resisting. I am not one of those enthusiasts, however, who claim that it will resist forever the vicissitudes of wind, storm, water, ice and climate. The consideration that claims similar to this can not be quickly disposed of is significant of age-resisting power.

Concrete is, when properly employed, easy to maintain. This is one of the chief reasons why concrete roads are now enjoying such popularity. There is no necessity for keeping a concrete structure painted. This is a great advantage.

One highly valuable quality of concrete relates to the ease of its manufacture. Everything but the ingredient used in the smallest quantity is ordinarily obtainable at or near the point of use. It can quickly be made and poured, and a minimum of skilled attention is necessary. In a short time after pouring it is usable. In other words, concrete lends itself to rapid and economical construction.

Standardized Units Tend to Lower Cost

There is, however, some modification necessary to make this statement generally true. The cost of forms is sometimes a serious matter tending to hinder the use of concrete. This objection is being met, in part, by an increasing standardization of constructional units. Thus knockdown forms may be made and used over and over again.

When concrete is used in considerable masses without reinforcement it is often possible to reduce its cost per cubic yard by the use of what are called "plums." These are simply sound rocks, properly freed from dirt and loose pieces, which are buried in the ordinary concrete. These may cost little. They replace equal volumes of what is usually a material costing much more money largely because of the necessary presence of portland cement.

Concrete is suited to a variety of methods of local transportation, after mixing, to the point of use. These are generally rather inexpensive methods. In short, concrete is usually cheap to place. It can be taken from the mixer to the place of its final use in a wheelbarrow, a hand bucket, a steel bucket of large size handled by a mule team, an auto-truck or tramway locomotive, or raised, lowered and swung by a derrick. Or a hoisting engine may handle a bucket or wheelbarrow between levels.

Concrete may be dispatched after mixing by means of

a closed or open chute operating by gravity, as shown in Fig. 5. Or it may be transported over horizontal distances running up to 1000 ft. through a pipe line, the drive being effected by compressed air. For shorter distances, a patented method of using steam is available. Further it may often be dispatched below ground by simply dropping batches of the dry ingredients down a vertical pipe to a mixer below, where the actual final mixing may take place.

Concrete may be mixed and placed in all weathers, though special precautions may be necessary in winter. Concrete may be placed in the open air or under water. There is now no great difficulty in successfully pouring concrete beneath water, although until recently this could hardly have been said. And I do not say that this can now be done without proper precautions. But what to do and how to do it are no longer unknown. As witness of this statement, I cite the placing of the concrete envelopes around the submerged steel tunnels in the Detroit River and in the Harlem River.

The use of concrete as a protective covering for steel is approved practice. This differs from the use of the two materials in the form of reinforced concrete. In the latter case the concrete is the principal constituent, the steel acting as a supplementary substance. In the former the steel construction is built and designed to perform the duty required, but needs protection from agencies which would tend to impair or destroy its usefulness. An overhead girder may, for example, be constructed of steel and may in this condition, without the addition or subtraction of anything else, be quite capable of sustaining the load placed upon it, provided the steel does not rust and is not injured by the heat from some accidental fire near-by. Concrete in such a case provides an envelope suited to protect against both the evils mentioned.

I have, so far, been dealing mostly with the good qualities of concrete. It may be well now to consider some of the qualities which concrete possesses either not at all or only in moderate degree. Thus, while concrete is admirably adapted to withstand the action of water, it is not readily made impervious to water, especially when it is under a considerable head. This consideration may or may not be important, depending upon the purpose for which the concrete is to be used. Where considerable heads are encountered the preventive practice seems to be now tending toward the addition of a protective covering of other materials.

Concrete may be made resistant to the penetration or percolation of water, whether under a head or not, by various means, but chiefly by increasing the density of the concrete itself. Again, concrete is well adapted to resist the wear and tear of the traffic on country roads; but this must not be magnified to the point where the traffic becomes not only excessively heavy in its amount but excessively severe in its action. In such cases the approved practice is to add a wearing surface of another material, superimposing this on the concrete foundation.

Again, concrete exposed to frequent alternations of freezing and thawing or of salt water and sunshine has in the past proved rather deficient. But even this difficulty is being surmounted, not so much by modifying the general mass of the concrete itself as by using an extremely dense exterior layer of concrete or cement mortar.

Again, the rigidity of concrete makes it ill-adapted for some uses though well suited to others. Thus it is not considered advisable to construct piers with concrete floor where the foundations of the pier are subject to uneven subsidence. The same objection would apply to concrete props in a coal mine unless the vertical rigidity of the prop can be reduced. There is some reason to expect that this can be done, as will be mentioned later. Wood props yield a bit and, as the stress rises toward breakage, they give notice of approaching failure. In short, they do not give way after the manner of a sudden collapse.

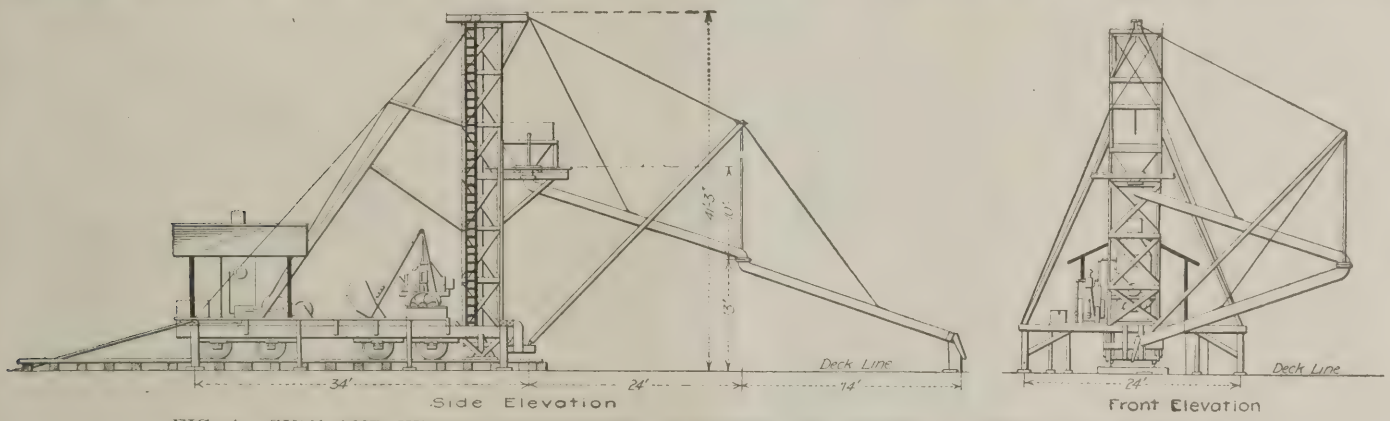


FIG. 4. SIDE AND FRONT ELEVATIONS OF MIXER AND CHUTE ILLUSTRATED IN FIG. 5

In Great Britain the coal-mining industry is confronted by excessive prices for wooden timbering. Naturally attention has been directed toward concrete. The cross bar of the ordinary three-piece set is essentially a girder or beam. The service to be performed is by no means a new one for concrete—that is, reinforced concrete. This case is that of a simple beam supported at its ends and loaded on top. It is thus subject to two kinds of stress. The load brings about deflection. On the top side the material is under compression while on the under side the beam is under tension (see Fig. 1). It is assumed that all the upper part of a beam is stressed in compression and that all the lower part is stressed in tension, and that the two parts are separated by a horizontal plane or by some other mathematical surface where there is neither compression nor tension. This is the neutral plane or neutral axis (if only a vertical section be considered).

Applying this analysis to the construction of a concrete mine bar, it is easy to understand that the steel

reinforcement should be located mainly in the lower half since this is the region where the concrete is unable to bear the tensile stresses. If the longitudinal reinforcement were evenly disposed, so that there were as much in the upper part of the beam as in the lower part, there would be a waste of steel. It is necessary for reasons of economy that the compression strength of concrete should be utilized. This means that little reinforcement need be used in the upper part of the beam, the bulk of it going into the lower part to perform the service that the concrete cannot perform. However, in the manufacture of bars and in their transport to the point of use, also in their handling during installation, the bars may be put under tensional stresses on all faces. Accordingly, it will not be advisable to go to the extreme of leaving any faces absolutely without reinforcement.

It is advisable to call attention to one matter. If bars are reinforced so as to resist tension on one side or face, they should be plainly marked or suitably shaped so as to indicate easily which side or face this is. Otherwise a bar made to sustain a given load might fail because of improper installation. The prop, whether used alone or as a support for a cross bar, must either itself yield or be conjoined with something that will. Offhand the concrete prop does not seem adapted to mine service. But one mining concern, the Haunchwood Collieries, has 5000 reinforced concrete props in use. These particular props are reinforced by four pieces of ½-in. wire rope. Generally they are octagonal in section and have a diameter of 5 or 6 in. The length is usually 6 ft. The cost, in England, is understood to have been about 5 or 6c. per linear foot of prop. The concrete is made of washed granite. The cost includes labor and material. The extreme lengths in use run up to 7½ ft. "They stood well where there was top pressure only, but where there was a side weight they were liable to crack. Even then, however, they gave warning, and before the crack had fully developed there was time to substitute another prop. They were tried in the face in front of the packs, but only where there was a soft bottom; it was of no use putting them where the bottom was hard. They had a good cap piece on the top, and the soft clay bottom allowed the prop to push its way downward. In the face, however, they invariably broke if any heavy lumps rolled up against them. Props were tried reinforced by four wire rods, but they did not seem to stand compression as well as those reinforced with wire rope. The wire rods were not brazed together in any way." These props were not proof against hammer blows.

I give this experience with concrete props to show that they are practical. It must not be understood, however, that I am indorsing the use of wire rope for reinforcement. That reinforced concrete can be made to resist severe shocks will be readily granted perhaps when I call attention to the fact that thousands of reinforced-concrete piles have been driven by hammer action. In most cases, however, the hammer effect was somewhat cushioned. Nevertheless there must have been a severe shock in order to get penetration.

It is proposed to use a system of reinforcement where longitudinal rods are welded to "triangular bracing" when manufacturing props. To get the yielding effect a base or cap for the bottom or top respectively might be used. This base or cap is provided with a suitable bearing surface to come into contact with the earth or rocks. The prop fits into a deep depression in the opposite face and becomes a kind of piston or ram. The cavity is partially filled with clay or some similar plastic material. With the prop pressing against this clay-like substance the necessary yielding effect might be secured by means of one or more small holes piercing the wall of the cavity. The base or cap may be made of concrete, cast iron or steel. If used as a cap instead of a base, it is easily recoverable after its service has been performed.

FIG. 5. GRAVITY CHUTE FOR DISPATCHING MIXED CONCRETE

Experiments made under a hydraulic press with a cast-iron base or cap and a stiff clay filling showed that a pressure of 23 tons (2240 lb. each) required 14½ minutes to produce a subsidence of $\frac{1}{16}$ in. when the outlet hole in the wall of the cavity was $\frac{3}{32}$ in. in diameter. It is understood that the diameter of the cavity was 5¼ in., thus giving a surface of about 21 sq.in. and a load of about 2450 lb. per square inch. Naturally the stiffness of the clay and the diameter of the outlet have a strong influence and furnish means of getting variations. These are provisions for introducing the yield. They are not always necessary, as

would seem to be indicated by the case of the Haunchwood Collieries.

A mine prop has been proposed which is constructed of steel tubing, wood and concrete (see Fig. 2). A representative case may be taken as a prop 5½ ft. long and 3¾ in. in diameter. The tube for this prop may properly be 3 in. inside diameter, thus giving a wall thickness of ⅜ in. The length is taken at 4¾ ft. This tube is filled with concrete except for a distance of 9 in. at one end. There will thus be 4 ft. of tube filled with a solid core of concrete and 9 in. empty. A wooden piece 18 in. long is now cut from a round stick 5 in. in diameter. Amidships a shoulder is arranged and 9 in. of the piece is reduced in diameter to fit into the tube. The remaining 9 in. is tapered to suit the probable service—say, for example, that a conical taper is made by reducing the diameter, in the 9-in. length, from 5 to 2½ in. This wooden piece is fitted into the open end of the tube. A crown or cap of any desired kind may be put on at the other end. The prop is now ready for service.

A mixture following the formula 1:1½:3 is suggested as suitable for the concrete filling. This seems unnecessarily rich. If a more moderate mixture is desired, the formula 1:2:4 or 1:3:5 would be suitable. Instead of a conical taper a wedge form may be used. When in service an excess load causes the wood tip to burr or broom. The tip thus saves the prop itself from destruction. It was stated about two years ago that there were several hundred of these props in use and that some had been set 30 or 40 times and that there had not been a single one lost.

A method of manufacturing a nontapered all-concrete prop has been worked out in England approximately as follows: A wooden form of collapsible construction is given a maximum length of, say 8 ft. (see Fig. 3). This will enable a prop to be given a maximum length of about 7 ft. Shorter lengths can be made with the same form. The prop is octagonal in section. The distance between opposite faces of the octagonal prism is 4¾ in. The size of the prop may be taken as roughly equivalent to that of a round one 5 in. in diameter. The assembled form is held together by bolts and will easily strip from the concrete prop as soon as these bolts are removed. The boards should be well greased or otherwise safeguarded against sticking to the concrete. Probably crude vaseline thinned with kerosene would be as suitable a grease as any. However, crude oil, linseed oil and soap solution are all usable.

Simpler to Use C-Clamps Instead of Bolts

In order to provide for shorter lengths the wooden strips may be slotted at proper points and a metal diaphragm slipped into the slots. Where a considerable number of props are to be made it will perhaps be found simpler to use C-clamps instead of bolts. In any case it may be found desirable to hold the form in the center as well as at the ends.

Mine props made abroad have been poured from concrete made on the formula 1:1¼:2¼. The fine aggregate was "cracker granite dust" instead of sand. This probably corresponds to our crusher dust. The coarse aggregate was clean ashes. I am reporting the ingredients and the proportions, not indorsing them. These things must stand or fall upon test. Most props were made hexagonal, the diameters being 3¾ to 4½ in., and the lengths 4½ to 6½ ft. A 6-ft. prop, ready for service, would weigh some 80 lb. Wire rope, to the average amount of about 7 lb. per prop, was used for reinforcement. Three or four strands were employed. Apparently the size of the strands was about ⅜ in. They were set about 1½ in. apart and kept so by wire. First concrete would be poured in until a layer 1 in. thick covered the bottom of the form. Then the wire arrangements to hold the rope strands were set.

It might be well for American operators and manufacturers to try out this idea of using old wire rope for reinforcement. It seems to have had a measure of success abroad. According to ideas prevalent here—and abroad too—a rope reinforcement is peculiar. It appears that the ropes are not always laid parallel but are sometimes crossed.

Ratio of Sand to Coarse Aggregate

As to concrete itself, whether used for props, bars or something else, the fundamental principle underlying the proportioning of the ingredients is that the cement combined with water shall be sufficient to fill all voids left in a mix of the sand and coarse aggregate. There is only the one binder. If it does not fill the interstices, then the concrete will necessarily be porous; and porosity may be taken to mean reduction in strength as well as in impermeability. Thorough mixing is good concrete practice, but no amount of mixing will take the place of cement.

As coal mines will probably want to use a considerable variety of aggregate, because of local convenience, it may be well to say a word or two on determining the ratio between the sand and the coarse aggregate that are to go into the concrete. The following principle may be taken as a guide. Use such relative amounts of sand and coarse aggregate as will produce a compact mass. A tentative ratio may be determined as follows: First put a known bulk of the coarse aggregate into a water-tight vessel. Then pour in measured quantities of water until the voids are all filled and the water is even with the surface of the material. The ratio between the two volumes will be the tentative ratio desired, the water corresponding to the sand. Next mix the sand and coarse aggregate in these proportions, using the mixer that is to do the actual work. Imitate the rate and period of turning that are later to be employed. Then see if the dry mix is really compact. If not, vary the amount of sand or coarse aggregate until compactness is secured. Water may be used with this mixture to determine tentatively the relative amount of dry cement to use. Then test out this relative amount. Probably more cement will be needed in order to cover the imperfections in mixing. The foregoing directions are based on the assumption that what is wanted is a thoroughly compact, strong concrete. Where porous concrete is permissible less care may be exercised.

Some years ago specifications for sand used to require that it be clean and sharp. It is still necessary or advisable that sand be clean. Otherwise, we have material present which will prevent the binder—the cement—from filling all the voids and coming in contact with the surfaces of sand and coarse aggregate. As to sharpness, no attention need be paid to it, since there appears to be no substantial reason to expect that angular particles of sand will make better concrete than rounded particles.

Determination of Sulphur in Coal

By EDWIN M. CHANCE
Formerly Consulting Engineer, Philadelphia, Penn.*

SYNOPSIS—*Precautions needed to secure a correct evaluation of the sulphur in coal and coke which can not be obtained unless all the needed precautions are taken. Artificial gas used in the conduct of the analysis is apt to be absorbed by the Eschka mixture.*

THE following is the method adopted by the American Chemical Society and the American Society for Testing Materials in the determination of sulphur in samples of coal and coke along the lines of the Eschka method:[1]

Apparatus—The following apparatus should be provided: Gas or electric muffle furnace or burners for igniting coal with the Eschka mixture and for igniting the barium sulphate; porcelain, silica or platinum crucibles for igniting coal with Eschka mixture; No. 1 Royal Meissen porcelain capsule, 1 in. deep and 2 in. in diameter which, because of its shallow form, presents more surface for oxidation and is more convenient to handle than the ordinary form of crucible; No. 0 or 00 porcelain crucibles or platinum, alundum or silica crucibles for igniting the barium sulphate. No. 1 Royal Berlin porcelain crucibles of shallow form and platinum crucibles of similar size may be used in place of the No. 1 Royal Meissen but owing to the deeper form somewhat more time is required for the burning out of the coal.

Solutions and Reagents—The solutions and reagents are as follows: Barium chloride solution, made by dissolving 100 g. of barium chloride in 1000 c.c. of distilled water; saturated bromine water, made by adding an excess of bromine to 1000 c.c. of distilled water; Eschka mixture, made by thoroughly mixing two parts by weight of light calcined magnesium oxide and one part of anhydrous sodium carbonate, both materials to be as free as possible from sulphur; methyl orange made by dissolving 0.02 g. of methyl orange in 100 c.c. of hot distilled water, the solution being filtered; hydrochloric acid solution, made by mixing 500 c.c. of hydrochloric acid of specific gravity 1.20 with 500 c.c. of distilled water; normal hydrochloric acid made by diluting 80 c.c. of hydrochloric acid of specific gravity 1.20 to one liter with distilled water; saturated sodium carbonate solution containing approximately 60 g. of crystallized or 22 g. of anhydrous sodium carbonate in 100 c.c. of distilled water; sodium hydroxide solution made by dissolving 100 g. of sodium hydroxide in one liter of distilled water. This solution may be used in place of the sodium carbonate solution.

Preparation of Sample and Mixture—Thoroughly mix on glazed paper 1 g. of coal and 3 g. of Eschka mixture. Transfer to a No. 1 Royal Meissen porcelain capsule 1 in. deep and 2 in. in diameter or to a No. 1 Royal Berlin crucible or to a platinum crucible of similar size, and cover with about 1 g. of Eschka mixture.

Ignition—On account of the amount of sulphur contained in artificial gas, the crucible shall be heated over an alcohol, gasoline or natural-gas flame as in procedure (a) below, or in a gas or electrically heated muffle, as in procedure (b) below. The use of artificial gas for heating the coal and Eschka mixture is permissible only when the crucibles are heated in a muffle.

a. Place the crucible in a slanting position on a triangle, and heat it over a very slow flame to avoid a rapid expulsion of the volatile matter, for any such speedy volatilization tends to prevent complete absorption of the products of combustion of the sulphur. Heat the crucible slowly for thirty minutes, gradually increasing the temperature and stirring until and after all black particles have disappeared, which is an indication of the completeness of the action.

b. Place the crucible in a cold muffle and gradually raise the temperature in about one hour between 870 and 925 deg. C. (cherry-red heat). Maintain the maximum temperature for about 1½ hours and then allow the crucible to cool in the muffle.

Subsequent Treatment—Remove and empty the contents into a 200 c.c. beaker and digest it with 100 c.c. of hot water for ½ to ¾ hour, with occasional stirring. Filter and wash the insoluble matter by decantation. After several washings in this manner, transfer the insoluble matter to the filter and wash five times, keeping the mixture well agitated. Treat the filtrate, amounting to about 250 c.c., with 10 to 20 c.c. of saturated bromine water, make slightly acid with hydrochloric acid and boil to expel the liberated bromine.

Make just neutral to methyl orange with sodium-hydroxide or sodium-carbonate solution, then add 1 c.c. of normal hydrochloric acid. Boil again and add slowly from a pipette, with constant stirring, 10 c.c. of a 10 per cent. solution of barium chloride. Continue boiling for 15 minutes and allow to stand for at least two hours, or preferably over night, at a temperature just below boiling. Filter through an ashless filter paper and wash with hot distilled water until a silver-nitrate solution shows no precipitate with a drop of the filtrate. Place the wet filter containing the precipitate of barium sulphate in a weighed platinum, porcelain, silica or alundum crucible, allowing a free access of air, merely folding the paper over the precipitate loosely in a manner that will let in the air but prevent spattering. Smoke the paper off gradually and at no time allow it to burn with flame. After the paper is practically consumed, raise the temperature to approximately 925 deg. C. and heat to constant weight.

The residue of magnesia, etc., after leaching, should be dissolved in hydrochloric acid and tested with great care for sulphur. When an appreciable amount is found this should be determined quantitatively. The amount of sulphur retained is by no means a negligible quantity.

Blanks and Corrections—In all cases a correction must be applied either (1) by running a blank exactly

*Since writing this the author has become Major of Ordnance, United States Army.

[1]Year-Book, American Society of Testing Materials, 1915, p. 605.

as before described, using the same amount of all reagents that were employed in the regular determination, or, more surely (2) by determining a known amount of sulphate added to a solution of the reagents after these have been put through the prescribed series of operations. If this latter procedure is adopted and carried out, say, once a week or whenever a new supply of a reagent must be used, and for a series of solutions covering the range of sulphur content likely to be met with in coals, it is only necessary to add to or subtract from the weight of barium sulphate obtained from a coal, whatever deficiency or excess may have been found in the appropriate "check" in order to obtain a result that is more certain to be correct than if a "blank" correction as determined by the former procedure is applied.

This is due to the fact that the solubility error for barium sulphate, for the amounts of sulphur in ques tion and the conditions of precipitation prescribed is probably the largest one to be considered. Barium sulphate is soluble in acids and even in pure water, and the solubility limit is reached almost immediately on contact with the solvent. Hence, in the event of using reagents of very superior quality or of exercising more than ordinary precautions, there may be no apparent "blank," because the solubility limit of the solution for barium sulphate has not been reached or at any rate not exceeded.

As shown in the preliminary report, the Atkinson and sodium peroxide methods give results in close agreement with the Eschka method. Register has shown that if 15 per cent. of nitrogen is present in the gases contained in the bomb calorimeter the sulphur of a coal is almost completely oxidized to sulphuric acid and the washings of the calorimeter may be used for the determination of sulphur.

The allowable variations are as follows:

	Same Analyst Per Cent.	Different Analysis Per Cent.
Sulphur under 2 per cent	0.05	0.10
Sulphur over 2 per cent	0.10	0.20

I have quoted this method in detail because it has been my experience that the short cuts and modified methods so frequently published generally fail to give satisfactory results in other hands than those of their authors. An experienced chemist, familiar with this sort of work can, in many cases, take advantage of his knowledge to reduce the amount of work this method requires where the highest accuracy is not required. This paper, however, is not intended for the experienced chemist as to him it would be but at best a twice-told tale. To the inexperienced, or to those unfamiliar with this sort of work, however, these short cuts are extremely dangerous, and to them many of the discrepancies in fuel analysis may be attributed.

The combustion of the mixture of coal and Eschka mixture may advantageously be carried out in a gasoline muffle furnace, such for example as the Case muffle furnace manufactured by the Denver Fire Clay Co. The advantage of this type of furnace is that it is self-contained and may be set up anywhere, being independent of gas supply or electricity. By using a furnace with an 8-in. by 12-in. muffle, a number of sulphur determinations may be run at once so that the work is expedited and simplified. I have found it advantageous to remove the capsules from the muffle after they have been heated for about 1½ hours and stir their contents thoroughly with an iron wire and then return them to the furnace. In this way the combustion is hastened and the danger that small particles of carbon at the bottom of the capsule will remain unconsumed is removed.

The coal sample for this determination should be ground until it will all pass a 60-mesh sieve.

In the standard method for the determination of sulphur, mention is made of the possibility of using the washings from the bomb calorimeter for the determination of this element. I have done a good deal of work on this method and as a result I am convinced that it is entirely worthless when applied to high-ash anthracites, as in this case not more than half the sulphur of the coal may be depended upon to be found in the bomb washings. With low-ash anthracite such as the better grades of "prepared sizes" about 75 per cent. of the total sulphur of the coal will be found in the washings from the bomb. It is decidedly unwise, therefore, to depend upon this method and its use should be discouraged.

I have spent much time in developing a volumetric method for determining sulphur in the washings from the Eschka mixture and have succeeded in working out a satisfactory method. In the long run, however, the volumetric was found to be but little more accurate than the gravimetric method, and certainly no more accurate, so it has been abandoned.

A word to the young or inexperienced chemist: Religious adherence to the recommendations of the standard method will secure the accuracy desired, divergence from them will cause errors in the long run.

Storage-Battery Locomotive Does the Business

In an anthracite mine at Hazleton, Penn., an Ironton 5½-ton storage-battery locomotive recently replaced a 10-ton trolley locomotive and three mules. This replacement was not due to the trolley machine being incapable of pulling. It arose solely from the fact that here, as in many mines, a 5- or 6-ton locomotive can handle all the loaded cars that are ever ready at any one time. It is not economy to use a locomotive much larger than necessary. The flexibility of the storage battery machine enables it to cover ground as well as pull heavy loads.

It is not unusual to hear some one sing out to the locomotive driver: "Say Bill! Have you got on all the cars she can pull?" The answer will come back, "Yes." "Then put on one more." This is hard on the locomotive, of course, and must be anticipated by husky construction.

The storage battery as built for mine-locomotive service does truly wonderful work if reasonably treated. A workman was recently reproved for putting water in a battery which contained material injurious to it. As it was good drinking water the man thought the complaint unreasonable. "I drinks that water," he growled, "and it don't rust me; and I guess it is good enough for that blankety blank battery!"

With one-half the consideration a mule gets in a mine, the battery will deliver a much stronger "kick." Moreover, the battery delivers the "kick" when it is wanted, and that certainly cannot be said of Maud.

New Methods of Handling Coal Electrically

By C. L. PACKARD
Schenectady, N. Y.

SYNOPSIS — *This article delineates the improvements in coal-handling equipment made by one company in the recent past. Among these are extreme sizes—large and small—of mine locomotives, a new type of locomotive controller and a shipping pier installation for transferring coal from cars to a ship's hold with a minimum of breakage.*

MANY applications of electrical equipment for the coal-mining industry have been contributed by the General Electric Co. during the past year. These cover transportation units and installations of types of standard apparatus in new sizes for hoisting and handling coal at the mine and seaboard and in industrial plants.

Early in the present year there was placed in service at one of the plants of the H. C. Frick Coke Co. a 30-ton, 48-in. gage mine-haulage locomotive equipped with three 125-hp., 500-volt driving motors and a type M multiple unit control, also both straight air and hand brakes. This locomotive is used for main mine haulage and develops 20 per cent. tractive effort (12,000 lb.) at 8.8 miles per hour. It is arranged so that two units can be operated in tandem, thereby bringing the two-unit capacity up to 60 tons.

Among the larger units under construction is one which, when completed, will be the heaviest locomotive of its gage and height so far built. It consists of a 40-ton, 36-in. gage, single unit articulated truck locomotive driven by four 500-volt motors. Its equipment includes automatic air brakes and HC control, which is similar in principle to the well known PC control, except that it is operated manually instead of by compressed air.

While this locomotive is intended for surface hauling, its dimensions are limited by the fact that its route includes a relatively low tunnel. Its overall dimensions are: Width, 6 ft. 1 in.; height over cab, 9 ft. It will develop 20 per cent. tractive effort (16,000 lb.) at 7 miles per hour.

The HC controller referred to was used for the first time on mine locomotives in 1917. As the locomotive units increased in size with corresponding increments in their current demands, it was found that the drum type of controller could not be utilized effectually on account of limited capacity, while the PC type necessitated the equipment of the locomotive with air compressors for their operation.

The HC controller is capable of handling the heaviest currents required by any mine locomotive in service or under construction. The main contactors are actuated by a cam which is in turn moved by means of a simple hand-operated lever. This type of controller was developed to handle 250- and 500-volt mine locomotives ranging from 15 tons rating to 40 tons. The arrangement of this control is shown in Fig. 2.

In contrast to the exceptionally large sizes referred to there was also produced the smallest practical mine locomotive ever constructed. This is a storage-battery unit

FIG. 1. A 30-TON MINE HAULAGE LOCOMOTIVE

rated at two tons, for operation on 20-in. gage track. It has a single driving motor which gives an effective drawbar pull at 400 lb. at 3 miles per hour. The battery is carried on a trailer having approximately the same dimensions as the locomotive. This machine is shown in Fig. 3.

This outfit was designed for underground service and to meet unusual conditions in mine development work. It is used on different levels in the mine, and its exceptionally limited dimensions—overall length, 48 in.; width, 34 in. and height, 35 in., as well as the fact that the step and operator's seat are removable—permit its ready transfer in the shaft cage from one level to another.

An important development in storage-battery locomotives was the production of a motor specially adapted for this service which rendered feasible the use of a single reduction gear drive. Prior to 1917 the motors applied to this type of locomotive were of the light weight, high-speed type originally designed for motor vehicle propulsion, and double reduction gearing was necessary in order to obtain the low speeds normally required for locomotives. The new motor has the same mechanical characteristics as those used on trolley type locomotives,

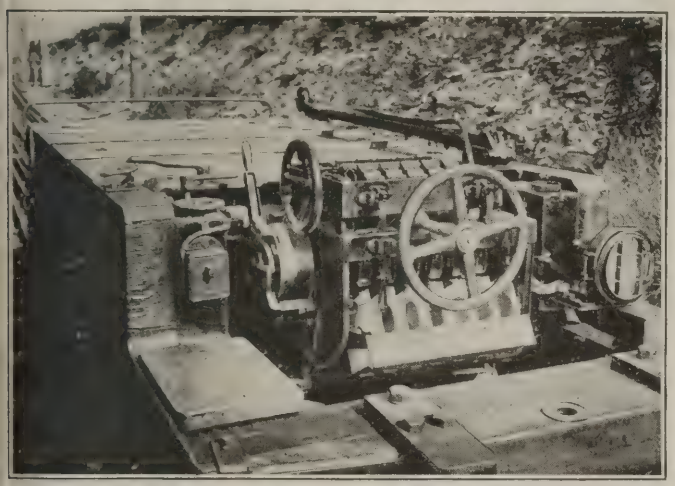

FIG. 2. NEW TYPE OF LOCOMOTIVE CONTROL

and with a slow-speed armature permits the efficient application of the storage-battery energy through single reduction gearing, thereby avoiding the use of the additional gear, pinion and countershaft heretofore required, and eliminating the friction losses they involved, simplifying the mechanical arrangement of the locomotive and reducing first cost and maintenance charges. The saving in energy consumption is, of course, specially important in that it increases the radius of action of storage-battery locomotives for each charge.

While the electrification of mine hoists in 1917 was not equal in number to those of 1916, a large number of installations were made, principally of induction motors. Upward of 90 equipments of 100-hp. and above, aggregating over 22,000 hp., were supplied. A particularly interesting installation was made at one of the Fairmont, W. Va., mines of the Consolidated Coal Company.

This was the initial installation of this type in an Eastern coal field and consisted of duplicate equipments of 1400-hp. capacity, operating on the Ilgner-Ward Leonard system. These equipments are designed to hoist 485 tons of coal per hour from a vertical depth of

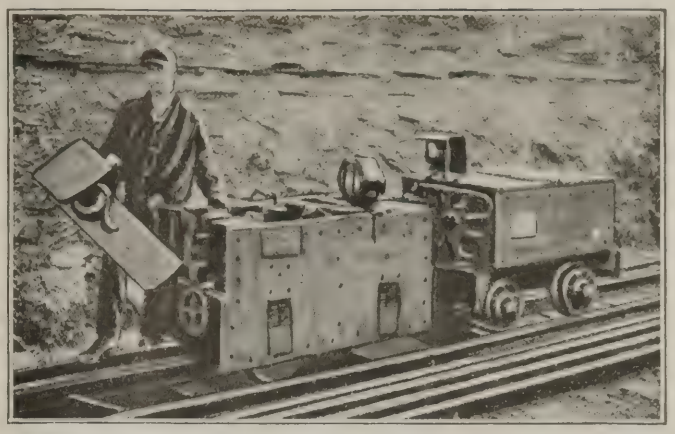

FIG. 3. DIMINUTIVE MINE LOCOMOTIVE

550 ft., 3.25 tons being handled per trip, with the cages operating in balance.

The hoist motor is rated 1400 hp., 90 r.p.m., at 550 volts, its armature being mounted on the same shaft with the winding drum. The drum is of the cylindro-conical type, the cylinder portions being 8 and 11 ft. in diameter. At full speed of the drum the cage speed reaches a maximum of 3100 ft. per minute. The slack rope system is employed in which the lower cage is landed and its empty car replaced by a loaded one during the time the upper car is being dumped. The hoist motor is supplied with power through a flywheel motor-generator set whose demand on the power supply is automatically limited to 600 hp., although the hoist motor develops a peak of 1800 hp. during hoisting.

For coal handling in quantity at an industrial plant equipment was supplied for two high-speed, alternating-current, hammer-head, coal-handling gantry cranes, provided with a unique system of dynamic braking. This was installed at the Steubenville, Ohio, plant of the La Belle Iron Works. Each crane is equipped with a 375-hp. slip-ring induction motor direct-coupled to a 40-hp. direct-current motor, and hoists a 4-ton bucket of coal at 500 ft. per minute.

Dynamic braking is obtained by combining the small direct-current motor with the alternating-current motor so that the direct-current unit serves as an exciter and gives dynamic braking, which is comparable with that ordinarily obtained with direct-current motors on this class of work. This is the first large application

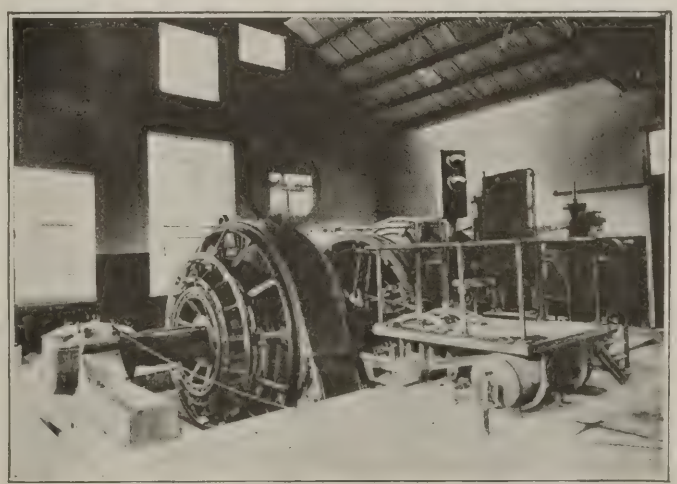

FIG. 4. DIRECT-CONNECTED MINE HOIST

FIG. 5. UNIQUE COAL-HANDLING CRANE

of this system of braking for cranes. It is more economical in first cost and has a number of practical operating advantages when compared with the method which utilizes a motor-generator set in addition to an exciter for securing dynamic braking for alternating-current hoist motors. Creeping speeds of 110 ft. per minute, lowering, are obtainable with cranes under ordinary service conditions.

An interesting application for car unloading and shiphold filling is the installation on one of the Baltimore piers of the Baltimore & Ohio R.R. This pier was designed and equipped for the rapid transfer of coal from cars to shiphold with the lowest possible breakage. Its equipment at the shore end of the pier consists of two steam-operated dumpers, capable of handling forty-five 100-ton cars per hour. In service this equipment has dumped 50-ton cars at the rate of 60 per hour.

The coal at the dumpers is deposited into hoppers and distributed by six short feeder belt conveyors to the conveying belt system of the pier. Two radial incline conveyors pivoted at the car dumpers also deliver directly to the power station hopper or to a balancing bin of 6000 tons capacity. The feeder belts travel at varying speeds and are driven by motors averaging about 15 hp. in capacity. Each incline conveyor utilizes a 150-hp. motor.

On the pier itself, which is 700 ft. in length, there are six longitudinal belts traveling at constant speed. The four inner or main conveyors are about 1000 ft. long, with 60-in. belts, and on either side of the pier is a 48-in., 820-ft. conveyor known as a trimmer. These conveyors all move at the rate of 425 ft. per minute. Each main conveyor is driven by a 300-hp. motor and carries coal at the rate of 1500 tons per hour. The trimmers are driven by 150-hp. motors and have a capacity of 1000 tons per hour each, making the aggregate delivery of the pier 8000 tons per hour. The pier is 110 ft. wide, and the six longitudinal conveyors occupy practically the entire deck space.

The coal is transferred from the four centrally located main conveyors to the hold of the ship by means of four transverse bridges arranged to travel lengthwise of the dock, and carrying shuttle conveyors from which the coal is finally delivered. The operation of the entire system of belts serving each of these bridges is centered in the bridge by means of remote electrical control.

The two trimmer conveyors likewise deliver coal by means of two traveling towers, which move along the sides of the pier, and are provided with 30-ft. projecting booms pivoted at the tower. These can swing 270 deg. horizontally and 90 deg. vertically and deliver the coal from the trimmer conveyors directly into the hold of the ship. The four shuttle belts are driven by 35-hp. motors, and the two trimmer towers and boom conveyors by 40-hp. motors.

In addition to the remote-control system for the widely separated motor drives, a unique arrangement of feeders furnishes current for the various motions of bridges and towers, without resorting to the complicated system of trolley wires or feeder rails with their concomitant contact shoes which would ordinarily be used. This control is accomplished by running all feeder cables in conduits along the deck of the pier and bringing them out through bellmouths located at suitable points, whence they pass over rollers to cable reels mounted on the movable bridges and towers. For the bridges, the necessary tension is maintained on the cable by suitable counterweights when winding and unwinding. In the case of the trimmer towers constant torque motors, similar to those used on mining-locomotive cable reels, are utilized in place of weights. Current supplied at 13,200 volts is stepped down for the operation of three 500-kw. synchronous converters, which in turn deliver current at 550 volts through eight main feeders.

Coke for Boiler Furnaces

By M. Meredith
Liverpool, England

It is not thoroughly realized by the majority of steam-plant owners that coke and coke breeze can be burned in boiler furnaces with considerable profit and at the same time to the advantage of the nation. The reason doubtless lies in large part in the fact that everyone is too thoroughly occupied with production to be able to spare much thought to changes and minor economies in the boiler house. Yet the difficulty involved is not as great as might be imagined.

S. G. Martlow gave some useful information on this matter recently. In a certain boiler house the partial substitution of coke and coke breeze for Welsh smokeless coal has effected a reduction of 20 per cent. in the fuel bill and saved $3750 in the course of the past year. The Lancashire boilers in which the coke is being burned had been equipped with patent hollow firebars, 17 to each furnace. One firebar was removed from each set and the bars put wider apart, so that the air spaces between bars were ½ in. wide instead of ⅜ in. The passages in the bars as well as in the pigeonholes under the bridge were plugged with refractory clay.

Each ashpit was closed by a casting carrying a pair of trumpet-shaped blower tubes acting as air ducts, and having steam jets controlled by outside stop valves. Except at times of light load forced draft is employed. Because of the situation of the plant smoke was not permissible (this being the reason for the former use of Welsh smokeless coal) and the coke entirely fulfilled this condition.

At the introduction of the byproduct fuel one of the instructions given to the firemen was: "When using coke, never entirely shut the dampers." This was to guard against the possible collection of gas in the flues at standing periods, which might lead to an explosion when the fires were stirred up at any time for a resumption of load.

Compared with raw coal the number of shovelfuls thrown on the grate is considerably more, owing to the difference in specific gravity of the two fuels. Bulk for bulk, the heating value of coke and breeze is less than that of a good coal and the volume of fuel per day put into the furnace is at least 50 per cent. greater; also, cleaning fires has to be done more frequently. Thus the firing is more trying to the men, and there is more clinker than when best Welsh coal (now practically unobtainable) was consumed. Account must naturally be taken of these factors in paying the firemen.

The accumulation of clinker has been diminished to a great extent by enlarging the gunmetal nozzles of the steam jets from the original 1/16 in. to ⅛ in. in diameter. With the larger jets such clinker as is deposited is more easily removed and the life of the gratebars is prolonged.

The saving effected in this case is borne out by the records from other plants. By using a mixture of slack and coke breeze in equal proportions, a saving of 30 per cent. on the fuel bill has been made in the case of a small generating station in the North of England, while considerably greater economies are being effected in plants that have been fitted out with the requisite apparatus for burning a mixture of coke and coke breeze.

Minecdotes

In Which the Mine Boss Emulates King Solomon

The mine boss and the master mechanic were sitting in the office, discussing the extension of a new pipe line, when two miners came in very much excited, disputing the ownership of a certain car of coal which had come up the day previous without a check.

Each presented his case to the mine boss, claiming that he was short one car and the car was his. The mine boss found from the weighmaster that only one car had come up without a check, and as both men had places where they pushed their cars by hand to a parting, he knew he would be unable to identify the particular car in question.

He therefore had no evidence whatever to help find the rightful owner, but in spite of this there was no hesitation whatever in his manner as he turned briskly to the two men.

"Now, I'll tell you what I'll do with you fellows. I don't know which of you owns that car, so the fairest thing I can do is to give each of you credit for half of it. Is that agreeable to you?" turning to one of the miners.

"Yes, that's fair enough," the man replied, after thinking it over a moment.

"And how about you?"

"It don't suit me at all. That car belongs to me, and I want it," the second miner replied.

"Well, you can go. I'll let you know after a while what I will do about it."

After the man had left, the mine boss spoke up to the first miner.

"You've got your nerve to try to put one over me like that. I happen to know that you didn't have your place ready to load coal yesterday until 4 o'clock, and then it was too late to get cars. You heard that we had a car without a check and thought you'd work me for it. I know your kind, and if you ever try to put over any more funny business like that on me I'll fix your clock right. Do you get me?"

The man protested a minute and then walked sheepishly out of the office.

"I'll hand it to you," said the master mechanic after the man had gone. "You handled that pretty slick. The fellow was a rummy, however, to try it when you knew about his having no coal."

"But I didn't know he had no coal. That was pure bluff to make him own up. Any man as willing as he was to split was pretty good evidence that he was getting something for nothing, and I figured if I went at him strong enough he would back down. It's part of the system."

"Well, I'll say one thing for your system; it's sure a good one."

"It ought to be," replied the mine boss. "It's about 3000 years old. Old Solomon was the first man on record to try it, and I guess he was as smart as they come."

[*Coal Age* will pay liberally for short, witty stories for this column. Contributions should breathe the atmosphere of the mine.]

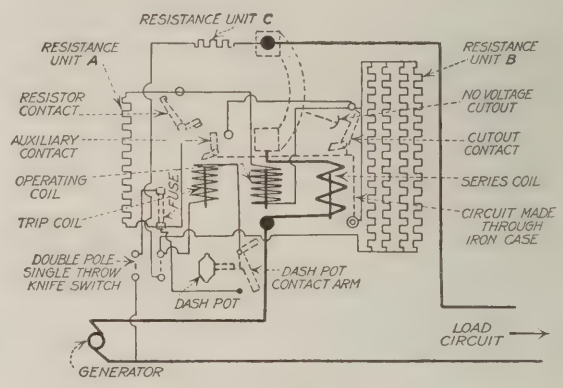
NEW APPARATUS AND EQUIPMENT

Stretcher for Pitching Places

A new stretcher has been developed for coal and metal mines modelled after that used by the Homestake Mining Co. of Lead, S. D. The construction of this stretcher is so strong and rugged that it has been shipped across the continent without any wrapping or crating whatever, yet despite this severe test of its availability for rough work the stretcher arrived in first-class condition at its destination.

STRETCHER FOR STEEP PLACES



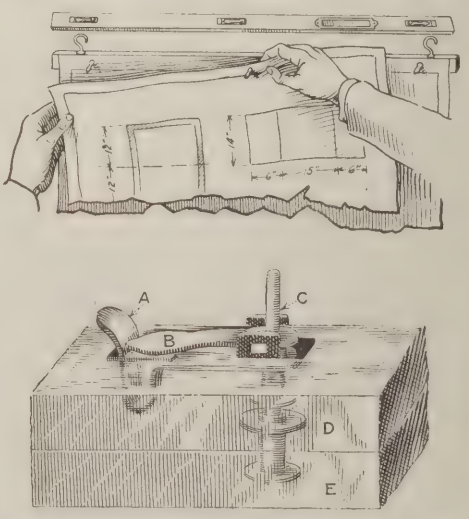
The strong safety feature of this new Homestake mine stretcher is that the patent is securely strapped thereon so that there is no chance of his further injury during transportation. The stretcher may also be raised vertically, up or down an incline, or skidded through the passages without disturbing the patient. For this reason it will undoubtedly prove valuable to many mining companies throughout the country. The Government is now using this stretcher in some departments, and it has been found to give every satisfaction.

The accompanying illustration gives an idea of the ruggedness and practicability of the Homestake mine stretcher for all phases of underground work. It is manufactured by the Mine Safety Appliances Co., Chamber of Commerce Building, Pittsburgh, Pennsylvania.

Automatic Reclosing Circuit Breaker

The Automatic Reclosing Circuit Breaker Co., of Columbus, Ohio, has recently brought out an improved form of automatic reclosing circuit breaker known as type "CN." This breaker is provided with a low voltage lock-out arrangement so that when the breaker is opened either by an overload current or by voltage failure the breaker cannot reclose until the trip coil has operated.

The trip coil can be adjusted so that it will not operate except when the voltage has been restored to 50 per cent. or more of normal value. The accompanying illustration shows the wiring diagram of this breaker. These breakers are designed especially for the protection of motor circuits in mines and industrial plants.



WIRING DIAGRAM OF BREAKER

They are built for 110, 250 and 600 volt direct-current circuits.

Holder for Blueprints and Drawings

A holder for blueprints, records, charts, drawings and newspapers is being marketed by the National Co., 275 Congress St., Boston. Two strips are provided, the upper one being removed when it is desired to add or take out material. These strips are clamped together by means of three catches which permit prints of narrow widths to be held firmly. The holder is suspended by hooks placed at the top. The catch, as shown in detail in the illustration, consists of a hardened-steel stud *C*, fastened to the lower strip *E*, and levers *A* and *B*, the latter being fastened to the upper strip *D*. The device is locked by pressing lever *B* and released by pressing *A*. The holders are made in 30- 36- and 42-in. sizes.

DETAILS OF NEW BLUEPRINT HOLDER

Electric Control Equipment of Mine Hoist

At Mine No. 2 of the Mission Field Mining Co., near Danville, Ill., 2800 tons of coal per day is being hoisted from the valley, where it is mined by stripping. The length of the incline from the valley to the tipple is approximately 1800 ft. This incline is shown in Fig. 1.

The mine hoist is of the traction type, electrically operated. The motor and the control equipment are located in a small house a short distance from the tipple. The motor is operated from 2300-volt alternating-current supply lines and is of 150-hp. capacity.

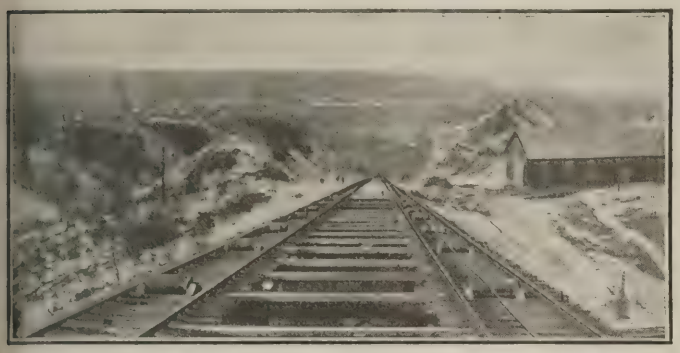


FIG. 1. NO. 2 INCLINE OF MISSION FIELD PLANT

At the top of the incline is a cab, or operator's house, mounted between the tracks from which the hoist runner can watch the loaded cars and shut down the hoist at the proper time by the simple manipulation of a master controller lever. This governs the operation of the magnetic control panel shown in Fig. 3, which is located in the motor house previously referred to.

When the operator at the Mission mine throws the master lever to the "on" or "run" position the series of magnetic switches carried on the control panel close in succession, bringing the motor gradually and safely up to speed by cutting out, step by step, the resistance which is connected in the secondary side of the slip-ring type of alternating-current motor employed. This motor is shown in Fig. 2. The resistance, which is of the grid type, may be seen above the magnetic control panel in Fig. 3. By means of this magnetic control the operator is kept away from the high-voltage current, since his master controller only handles control current which is of low potential. At the bottom of the panel two primary, solenoid-operated, inclosed, oil-immersed switches are mounted. These close and open the main primary circuit to the motor.

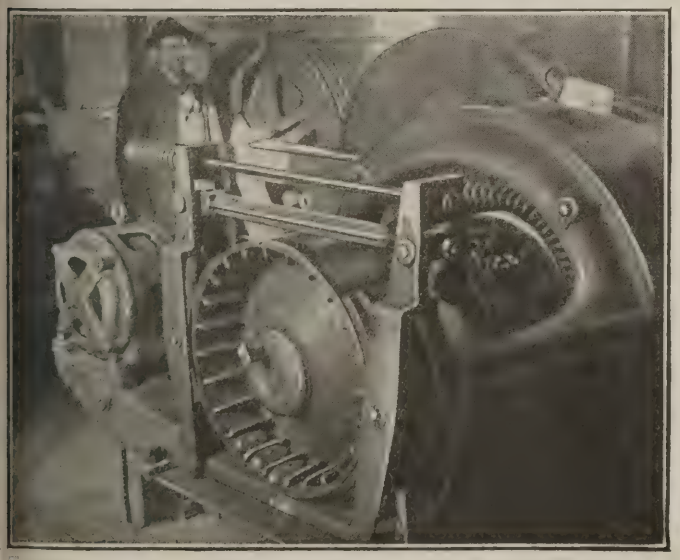

FIG. 2. MOTOR WHICH RUNS THE HOIST

When the operator throws the master lever to the "off" or "stop" position, the magnetic control panel cuts the motor from the line and inserts the resistance in the secondary circuit ready for the next start. A brake of the motor-operated reversible-shoe type is also actuated and brings the motor to a quick stop. This brake appears rather large in comparison to the hoist motor in Fig. 2 because it is in the foreground. The small motor on the end of the brake applies the braking power and replaces the solenoid magnet of the usual direct-current brake. A small pinion on the motor shaft engages with a toothed quadrant which is linked to the arms carrying the brakeshoes. When power is applied this small motor revolves until the brake is released. It then stalls and maintains the brake in the released position until the power is cut off. Adjustment for wear is easily effected by turning a nut on the thrust rod. This brake, as well as the magnetic control apparatus, is manufactured by the Cutler-Hammer Manufacturing Co. of Milwaukee, Wisconsin.

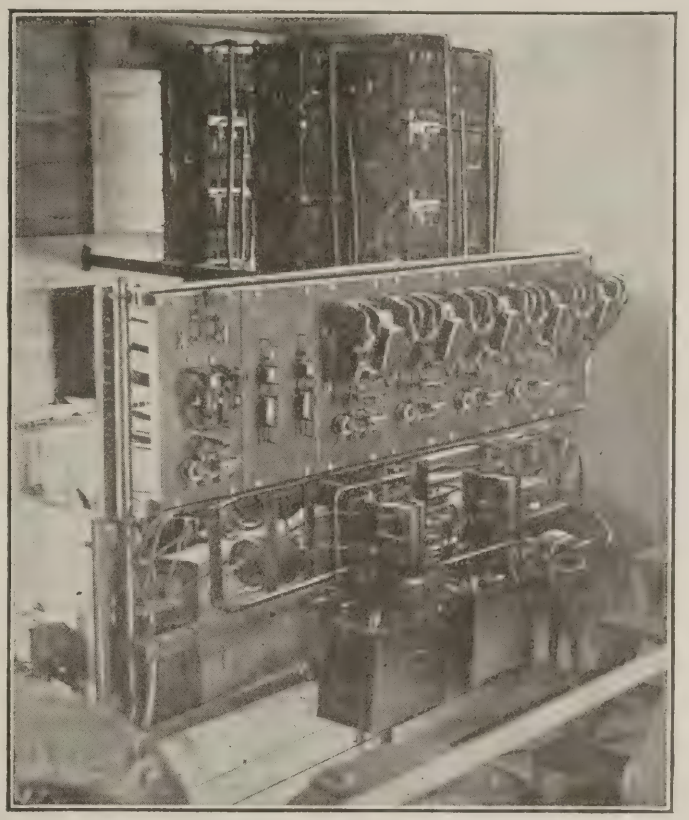

FIG. 3. MAGNETIC CONTROL PANEL

Experience with burning soft coal shows that if soot is once formed a large percentage remains floating in the gases after all other gaseous combustible has been almost completely burned. In a hand-fired furnace analysis of the flue gases will sometimes show no CO when at the same time black smoke is coming out of the stack. Even a large combustion space is not an unfailing solution for burning soot, without a large excess of air.—*Bureau of Mines Bulletin No. 135.*

Nature of Mine Explosions

By H. E. GRAY
Confluence, Penn.

SYNOPSIS—*What the term "explosion" really means, in its application to coal mines. Effect of an explosion in mine workings. The production of air waves, and "trill" of the air previous to the detonation that wrecks all in the path of the fatal blast.*

THE general mining public is sometimes electrified and shocked by newspaper accounts of explosions in mines. No doubt we often wonder how and why such accidents happen. As far as I am able to learn, there is no information yet obtainable which enlightens us fully as to the nature of this great death-dealing factor in mines.

Our textbook definition of the term "explosion" is a "very rapid combustion taking place and accompanied by a violent and destructive expansion of the gaseous products." Such an explanation, however, fails to furnish an adequate idea of the true nature of a mine explosion. The gruesome discoveries, made by rescuing parties after firedamp has done its awful work in a mine, has proved beyond a doubt that the terrible expansive force developed in the narrow confines of the mine is responsible, to a large extent, for the destruction of lives and property in the underground workings.

The mine cars are overturned and demolished, bodies of animals and men mutilated beyond recognition, tracks torn up and other objects lifted bodily and thrown to one side of the passage. Tons of coal and slate are thrown down by the terrible force of the explosion, and obstruct the airways and traveling ways.

My desire is to make clear what constitutes a mine explosion, from the time of its inception, when conditions are practically normal, until it has reached its full development. It should be understood that in considering explosions that occur in underground workings, we have to deal with conditions that differ materially from those that exist in the open atmosphere.

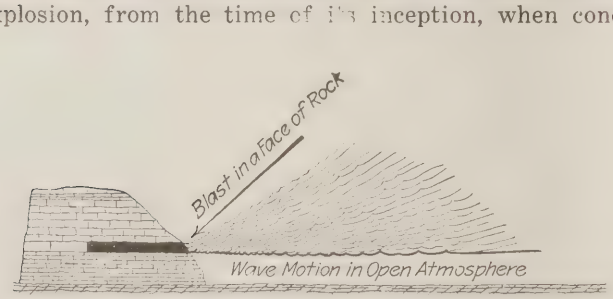

FIG. 1. ILLUSTRATING A BLAST IN THE OPEN AIR

In the case of an explosion of any material on the surface, the air waves produced by the shock or concussion radiate from a common center, in all directions. The greatest velocity of wave motion is at the center of disturbance, or where the explosion originated. Here the waves are shortest and increase in length as they recede from that center till lost in limitless space, as I have attempted to illustrate in the accompanying sketch (Fig. 1), showing the effect of a blast in a hillside.

When an explosion occurs in the open atmosphere, we may observe the following: (1) The explosion develops its maximum force in a moment of time. (2) The vibratory waves produced are not confined within narrow limits, but are free to expand in all directions, into boundless space.

On the contrary, when an explosion occurs in a mine the explosive wave is forced to travel with great velocity through the narrow air passages, and the effect is often increased as it goes by the aid of firedamp and fine coal dust, which is thrown into the air and consumed by the heat and flame of the blast.

In my opinion, a mine explosion develops a vibratory movement of the atmosphere in the mine, resembling the trill of a human voice, and this may be produced

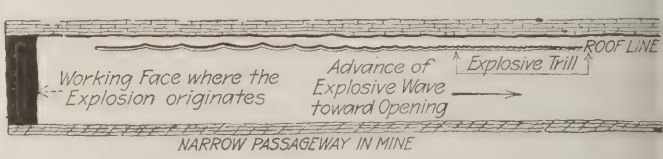

FIG. 2. SHOWING EFFECT IN A NARROW MINE ENTRY

either with or without the aid of heat or flame. For instance, I believe that a trill movement may be set up in a mine atmosphere by a rapid subsidence of the roof strata over a large area. The most disastrous explosions, however, are always accompanied by a solid wave of flame.

An explosion of gas in a mine may not develop its full force instantaneously, but there is often a gradual development from the place of its inception to the point where it "trills," as I like to express it, or explodes.

The chief elements in the development of a mine explosion are the volume of gas or dust consumed, intensity of heat or flame producing ignition, and the air space or area of the immediate working places.

The movement of the original explosive wave in a mine must always be in a forward direction; and this movement in one direction must be maintained or, as I believe, it will be impossible to develop an explosive trill. The turning back of the flame over the path taken I think, invariably results in its extinguishment and terminates the explosion. I would say that the distance traveled by an explosive wave, from the point of origin to the point where it trills or explodes, is usually about 200 feet.

For sake of illustration, let me assume a narrow passageway in a mine, 1000 ft. in length, and that somewhere near the working face is an accumulation of fire damp, sufficient in volume and quality to produce a violent explosion. In some manner this body of fire damp is ignited and produces a large body of flame. The heat of the flame causes a rapid expansion of the surrounding air and gas.

All of this has taken place in a moment of time, and the entire mass of air and burning gas is driven for

ward, in a single direction by the force of expansion. Because it is confined within narrow limits on all sides, except in the direction of the mine opening, there is formed an advancing explosive wave that moves forward consuming the dust and gas in its path, whereby the temperature and explosive energy are momentarily increased.

The vibratory waves, however, gradually shorten as the propelling forces behind and the retarding forces ahead produce a compressive effect. Every moment increases the velocity of the moving mass of flame and gases, the waves gradually shortening until the climax is reached by a fine vibratory trill movement, and the real detonation of the mass immediately follows. I have again attempted to illustrate my idea, as shown in Fig. 2.

As I have previously stated, men, animals and other heavy objects are picked up as so many feathers in a windstorm and hurled against the roof and sides of the mine. The explosion has now done its work. One thing still remains for us to try to do and that is to show how explosions in mines may be prevented.

Upkeep of Adequate Motive Power

In speaking before the United States Chamber of Commerce in its sixth annual meeting in Chicago recently, Alba B. Johnson, president of the Baldwin Locomotive Works, took the ground that Congress should place upon the functionary charged with the making of railroad rates the responsibility of making the rates sufficiently high for thorough maintenance of the roads.

Tracing briefly the development of the locomotive from the days when they weighed five tons each to the present type, weighing more than 500,000 lb., Mr. Johnson showed how the spur of competition had been responsible for America's progress in handling its vast transportation problem up to its present high point of efficiency, where "American railroad men need have no fear of comparison with other countries either in the encouragement given to improvements in engineering practice or in the reductions which have been achieved in the cost of transportation." Continuing, Mr. Johnson said:

> The participation of the United States in the world-war has brought about new conditions. A mass of legislation and regulation which had accumulated during years of peace and which was predicated upon certain popular fears and prejudices resulted in the failure to allow increase in revenues corresponding to increased costs. The necessities of the war soon demonstrated that these regulations which prevented coöperation by insisting upon competition, did not make for efficiency, but prevented many measures of improved service which the railroad managers were themselves eager to adopt but which had been made prohibitive. In order at a single stroke to untangle this situation, the Government decided that it was wise to assume control of transportation by placing all the principal lines in the control of a director general of railways, and to operate the roads as a unit during the period of the war and for a fixed time thereafter. For the first time in the history of the country all of the railroads became subject to a unity of management and to a unity of control in their purchases. For the first time it became practicable to adopt and to enforce standards to a large extent.

The whole problem of standardization Mr. Johnson discussed at length, pointing out the obvious operating advantages on the one hand and contrasting with them the possibilities of the paralysis of invention and the stagnation of new improvement on the other. "It would be an evil day," he said, "for American engineering, for American progress in the art of transportation, which would involve a policy of discouragement to new and useful improvements in the art. We should therefore look carefully before we leap, to make sure that we are not giving up the substance of continued growth in efficiency and economy, to grasp the chimera of standardization. Especially should this be considered most carefully when the world-wide danger of this war is upon us."

Turning to the remarkable growth and development of electric power in transportation, he briefly reviewed its history from the electric locomotive ordered by the Northern Pacific in the early '90's up to the present when electrical engines are part of the standard equipment of such lines as the New York Central, the New York, New Haven & Hartford, the Pennsylvania, the Chicago, Milwaukee & St. Paul, the Norfolk & Western, and others. As to the future relationship between steam and electricity, Mr. Johnson said:

> Doubtless the electrification of suburban lines and the application of electricity to lines having great density of traffic will be financially justified, and as these grow in number and join themselves together electric zones will be created in which it will be economical to adopt electricity exclusively as the motive power. Any question of rivalry between the steam and electric locomotive may be set aside. The problem is wholly an economic one, the only question being as to which is the more efficient and suitable for the particular conditions, and the consequent adoption of one or the other is dependent upon the geographical or other circumstances governing each case.

Speaking of the admittedly inadequate motive power of our present equipment, Mr. Johnson said:

> During the depression preceding the war there was a small surplus of power which, as should have been foreseen, was absorbed in traffic with the first increase of activity. As a rule, railroads have purchased locomotives largely under the spur of excessive traffic and have abstained from purchasing during periods of reduced earnings. This is contrary to the economics of the situation. Enlargements of facilities should be made in times of depression. The reason the railroads have not done this since 1907 is that under the regulatory policy which went into effect at the time, railway managers have not been able to accumulate surpluses sufficient in their judgment to warrant bold construction in times of small earnings, and especially because future earnings have not been susceptible of approximate calculation even where the volume of traffic could be estimated in advance. Adequate provision of motive power, like adequate provision of other rolling-stock and other facilities, can only be assured when Congress places upon the functionary charged with the duty of regulating rates, the definite responsibility of making such rates as will yield earnings sufficient for thorough maintenance, for adequate improvements and sufficient to attract the capital necessary for providing additions and extensions.

The low percentage of combustible in the furnace gases when the excess of air is large is not entirely a result of improved combustion, but to some extent is due to the dilution of the gases with air. It is evident that with a large excess of air, the percentage of combustible gases is less, even if there be no improvement in the combustion. Therefore, when the air supply is varied the percentage of combustible gases does not reliably indicate the completeness of combustion.—*Bureau of Mines Bulletin No. 135.*

Weekly Production Statistics

A break occurred during the week ended May 4 in the steady increase in production of bituminous coal which had taken place for three successive weeks. The decrease over the record production of the week ended Apr. 27 was 2 per cent. Telegraphic advices to the Fuel Administration show that the production for the week ended May 11 practically equals that of the week ended May 4. During the week ended May 4 production totaled 11,559,000 net tons.

Anthracite forwardings were 40,570 cars, thus showing a substantial increase over the week ended Apr. 27 and preserving unbroken the recurring increase since the first of April.

Beehive coke production fell off to 657,000 tons during the week ended May 4. The decrease was a full 11 per cent. Shortage of labor is given as the principal cause. Byproduct coke production showed a gain over the week of Apr. 27 and now stands at practically 90 per cent. of the full-time capacity of the ovens.

The estimates given above are those of C. E. Lesher, the geologist in charge of coal statistics for the United States Geological Survey.

Fuel Administration Asks Appropriation

Congress has been asked to devote $4,575,000 for the maintenance of the Fuel Administration from July 1, 1918, to June 30, 1919. The appropriation is to be supplied as follows:

Salaries	$2,392,000
Temporary employment	381,000
Traveling expenses	750,000
Services other than personal	565,000
Supplies and equipment	368,000
Purchase, operation and maintenance of passenger-carrying motor-driven vehicles for use of United States Fuel Administrator, his assistants and deputies, in the business of the Fuel Administration	10,000
Law books, periodicals, and books of reference	5,000
Rent	104,000
	$4,575,000

Drive for Coal Orders To Be Made During "Coal Week"

The marked success which has attended the setting apart of a week for Liberty Loan and Red Cross drives has led the Fuel Administration to designate the week beginning June 3 as "Coal Week." During that week systematic efforts will be made throughout the country to secure the booking of coal orders. Dealers are to be asked to give publicity to the fact that purchases of domestic fuel will be delivered in the order of their receipt.

To Supervise Distribution of Lake and Canadian Coal

In order that special attention may be given the distribution of Lake and Canadian coal, C. P. White has been placed in immediate charge of these activities of the Fuel Administration. For 20 years Mr. White was in charge of Lake Superior coal dock properties. This experience brought him in close touch with the fuel needs of Canada and the Northwest. He also has been connected with the coal department of the Wheeling & Lake Erie R. R. and formerly was in charge of the Pittsburgh Coal Co.'s operations north and west of Chicago. For a time he was vice president of the Carnegie Dock and Fuel Co. with headquarters at Minneapolis. Until recently Mr. White has been general manager of the Clarkson Coal Mining Co., which conducts operations in eastern Ohio.

Railroad Fuel Question Still Unsettled

Illness of Director General McAdoo made impossible last week further steps looking to the settlement of the railroad fuel controversy. Reports to the Fuel Administration show that the railroads are buying on a hand-to-mouth basis and are not entering into contracts. Loss of production is resulting from the fact that operators cannot enter into contracts with others, as they know that the railroads must be supplied with fuel.

To Conserve Power Plant Fuel

Fuel conservation in power plants is to be insisted upon by the Fuel Administration. Active steps in this direction are being taken. Thomas R. Brown, of Pittsburgh, Penn., has been appointed administrative engineer for the Pittsburgh district, with C. P. Dilling as his assistant. Other administrative engineers will be appointed for other districts.

The Fuel Administrator hopes to save 50,000,000 tons of coal during the next year in industrial plants. This is to be done largely by correcting firing and operating methods. Each power plant is to be inspected personally. Each plant will be rated on the basis of the thoroughness with which the conservation regulations are carried out.

While no mention is made by the Fuel Administration that plants with the lowest ratings will be the first to be cut off from fuel supply, when there is not enough coal to go around, it is believed that that practice will be pursued.

New Regulations Affecting Shipment and Sale of Bituminous Coal

A regulation issued on May 13 by the United States Fuel Administration prohibits the shipment by way of the Great Lakes and the sale, distribution and use of smokeless coal from the Pocahontas and New River districts in Virginia and West Virginia, for domestic purposes in Wisconsin, Minnesota, North Dakota, South Dakota and Iowa.

By an additional regulation bituminous coal from the states of Pennsylvania, Ohio, Maryland, West Virginia, Virginia, Eastern Kentucky and Tennessee, is barred from shipment by way of the Great Lakes into the State of Illinois for sale, distribution, or use for domestic purposes.

Lake forwarders, dock owners, wholesale and retail dealers, and others are warned of severe penalties for violation of the orders in disposing of coal from the Lake ports for domestic uses where the coal has come from the prohibited districts to the Lakes for blacksmithing and byproduct uses as permitted by the zoning orders put into effect by the Fuel Administration and Railroad Administration on April 1.

Under the zone plan coal from these districts when shipped to the Lakes must be used for certain specified purposes and those coals named are among those prohibited under the zone plan for domestic use. The new regulations are designed to prevent the coal, after reaching the Great Lakes, from being transferred and distributed for domestic purposes. Both regulations are made effective at 7 a.m., May 27.

A third regulation issued today by the Fuel Administration widens the zone in which coal from the Lake Superior docks may be sold and distributed so as to include all points in the State of Montana, located along the line of the Minneapolis, St. Paul & Sault Ste. Marie Ry. between Westby, Mont., and Whitetail, Mont. This order is effective May 20.

To Curtail Use of Fuel Oil

No significance should be attached to the fact that the Fuel Administration has in mind the curtailment of the use of fuel oil in the States of Oregon and Washington, according to Mark L. Requa, the head of the petroleum division. Local conditions in those states, Mr. Requa says, probably will require such action. He explained, however, that it does not hold that fuel oil is to be denied consumers in other sections where coal is available.

Maximum Prices Fixed on Beehive Coke

Beehive coke made in Wise and Lee Counties of Virginia must not be sold for more than $7.25 a ton f.o.b. cars at the ovens. The price of 72-hour selected foundry coke is fixed at $8.25.

At the Howe plant in Oklahoma the price fixed for blast-furnace or smelting coke is $10.75, and for 72-hour selected foundry, $11.75.

Screened and sized crushed beehive coke made anywhere in Colorado is subject to a maximum price of $9.80, according to an order issued last week by the Fuel Administration.

Tonnage Lost Because of Car Shortage

A table, showing the full-time capacity of mines in the more important producing fields and the loss during the week ended Apr. 20, due to car shortage, has been compiled by the Geological Survey. It follows:

Producing Field	Full-Time Output Tons	Production Lost Because of Car Shortage—Tons
Illinois	2,370,000	322,000
Indiana	640,000	112,000
Southern Ohio	460,000	243,000
Northern and central Ohio	930,000	293,000
Western Pennsylvania	2,075,000	263,000
Central Pennsylvania	1,882,000	147,000
Somerset County, Pennsylvania	153,000	70,500
New River and Winding Gulf	413,000	114,000
High-volatile fields of Southwest Virginia	825,000	265,000
Fairmont, W. Va.	230,000	102,000
Cumberland and Piedmont	214,000	17,000
Northeast Kentucky	230,000	37,000
Western Kentucky	320,000	33,000
Southern Appalachian	428,000	20,000
	11,170,000	2,038,500

No Coke To Be Shipped to New England

New England must rely on itself for coke. An order has been issued by the Fuel Administration forbidding the shipment of coke, made in New England, outside of those states except to Albany, Cohoes, Green Island and Troy, New York. Shipments of coke into New England from other states are also prohibited.

Plan To Reorganize National Coal Association

A plan for the reorganization of the National Coal Association is to be presented at the annual meeting to be held in Philadelphia, May 28 and 29. The form of organization will be changed from a temporary one to a corporation. It is proposed to incorporate it under the laws of the State of Delaware. There are to be 37 directors, as follows:

Washington, Iowa, Indiana, Alabama, Michigan, Virginia and Maryland, one director each. Montana and Northern Wyoming, one director. Utah and Southern Wyoming, one director. Colorado and New Mexico, one director. Arkansas, Oklahoma and Texas, one director. Kansas and Missouri, one director. Tennessee and Georgia, one director. Western Kentucky, one director. Eastern Kentucky, one director. Ohio, two directors. Pennsylvania anthracite, two directors. Illinois, three directors. West Virginia, three directors. Pennsylvania bituminous, four directors. Eight directors at large also are proposed. An initiation fee of one-fourth of one mill on each ton of annual production will be charged.

Brief Washington Notes

Zone B regulations have been changed so that shippers may forward smithing coal into the area west of the western boundary of North and South Dakota, but not south of the southern boundary of Zone B.

No anthracite will be allowed to move west of the Mississippi or into the South, it is understood. It has been deemed necessary to restrict the consumption of anthracite to those sections of the country where it is most greatly needed and which are not too distant from the points of production.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The strike of the coal miners in the Huntingdon and Broad Top region of the bituminous coal field of Pennsylvania was not unexpected. The wage provided Dec. 4 of last year was arranged to end Apr. 1 of this present year. The operators apparently thought that December was not a seasonable time for resisting a strike and preferred to shelve their difficulties rather than to face them.

In effect they seem to have believed that Apr. 1 would find such a slackness of market as would make them and the public generally indifferent whether the mines worked or were idle. Some may have thought the war might by that time be at an end.

Early last winter there were in the country plenty of optimistic people who believed that the war game would never be played to a finish, that the players would lay their cards on the table, the Kaiser then conceding that it was useless to hope to win as against the full hand of Uncle Sam. We now know that the Kaiser was figuring on the man-power of Russia; we have recently seen two big salients driven into the British line, and we are now more ready than ever to admit that several Mitchell days may go by before the war comes to an end.

As the war excitement became greater rather than less, Apr. 1 found the demand for coal almost as great as on Dec. 4. Consequently the miners' strategic position is in many ways as good or better than in the year past; for the demand for coal is still severe, and now the miners can claim that the scale they are asked to accept is a reduction from the former scale. Had the higher scale never been granted that could not have been said.

The rate of mining per ton during the winter was $1.11. It is now $1.01. The yardage rate is also cut 8 per cent. As stated, the change in rate took place Apr. 1, but the mine workers did not strike immediately. They accepted one pay at the lower rate and finally quit on May 8.

CARS WILL GO TO IDLE MEN IN OTHER FIELDS

The laying idle of this small area need not reduce the output of bituminous coal. The cars it would normally receive can be shifted to other sections of the country where the men have been satisfied to fare as well as, and no better, than their fellows. The output of the region is not large, only 8500 tons a day. As some big single mines produce an equally large amount of coal it would be a small matter were the whole tonnage of the Huntingdon and Broad Top region lost to the country, but, as stated, this 0.45 per cent. of the whole national tonnage can be readily supplied elsewhere by miners who would otherwise be kept idle for lack of cars.

The fact that the Huntingdon and Broad Top miners got a larger wage than the rest of the miners in central Pennsylvania was the reason for the recent dissatisfaction in that large and important region. To give the miners in the Broad Top region what they ask is likely to make trouble in the larger area. To deny it to them is likely to result in greater satisfaction. Everything seems to show that the improvement in the strategic position of the Broad Top miners is offset by the knowledge that what they ask can only be conceded by raising up difficulties which cannot be dismissed with indifference.

On May 9 the only mine in the region still working was that at Jacobs. A meeting, called by Fuel Administrator Garfield, was to be held May 17 at Washington, D. C., but at the time of going to press the delegates to that meeting were not yet in session.

Another development of interest is the determination of the Consolidation Coal Co. to enter into contract relations with its men. The company has always been a model employer, but it has resolutely combated the unionization of its workmen, feeling that a union meant an organizing of discontent. Operators have feared that discontent became chronic wherever an institution was formed with the apparent purpose of keeping such discontent alive. Some men who read patent-medicine advertisements are ready to crawl into the grave, imagining they have all the ills described, and similarly some well-satisfied men who join a union begin to sense all manner of social ills as soon as they are suggested to them. A fear of something akin to hypochondriacism makes operators afraid of the spread of union activity.

On May 9, George T. Watson, president of the Consolidation Coal Co., at a meeting of the leading operators of the Fairmount region said as follows: "The war has changed everything. The get-together spirit is in the air. Labor and active capital are working together in a common cause—winning the war—and real democracy is sure eventually to triumph.

CONSOLIDATION COAL COMPANY GRANTS OPEN SHOP

"The Consolidation Coal Co. heads have, for some time, been engaged in formulating a plan of getting-together with their men. Consequently, the present action is not exactly sudden, though the determination to put it into effect came very suddenly, without giving the opportunity for such a general consultation as we would have preferred.

"The coal industry has never had a clear sky until now. It has been handicapped by conditions which are being remedied by the coöperation of employer and employed with the United States Fuel Administration."

The Consolidation Coal Co. is proposing to have mine committees at all its mines and plans to welcome the appointment of an umpire by the judge of the United States District Court, whose appointment will be subject to the approval of the United States Fuel Administration and who will be payable by the company and the employees conjointly.

On May 6 the aides of the United States Fuel Administrator, Rembrandt Peale and John P. White, proposed a solution for the Maryland trouble which solution follows closely along the lines of the Alabama settlement, namely: (1) Mine committee of three at each mine. (2) Secret balloting for that committee. (3) No grievances to be discussed during working hours by mine committees. (4) Reference of debated matters to manager and, if not settled in three days, further reference to an umpire. (5) Matters must be submitted to umpire within 30 days or right of appeal will be denied, unless an extension of time has been agreed upon. (6) All agreements shall be in writing, shall be final and not subject to appeal. (7) Umpire shall be appointed by Judge Rose of the United States District Court of Maryland and be subject to the approval of the United States Fuel Administration. (8) Should two nominees be found unsatisfactory, the administration itself is empowered to name the umpire. (9) The umpire shall be paid by operators and mine employees jointly each contributing one half of salary. (10) Mine committee members to be protected against discrimination except when using intimidation or coercion. (11) Right of reëmployment conceded to employees discharged for affiliation with the union. (12) Right to have a check weighman on each tipple where coal is weighed. (13) Checkweighman shall not be elected more often than once in three months unless a vacancy exists. (14) Checkweighman shall be paid by a check-off taken from the wages of hand and machine miners and loaders. (15) The turn shall be even. (16) Pay day shall be semi-monthly. (17) The penalty for

interrupting the operation of a mine or causing a strike is $1 per day for each day or fraction of a day the mine worker lies idle. (18) The penalty for a lockout is a dollar per day for each mine worker affected. (19) All fines are payable to the American Red Cross through the umpire. (20) The agreement shall continue in force at least two years or for the duration of the war, whichever is the longer period of time. Thereafter it shall be subject to revision upon 90 days' notice by either of the parties.

The action of the Consolidation Coal Co. and the anticipated action of the United States Steel Corporation seems to make the "open shop" in the mines of the United States almost an accomplished fact. A few ununionized sections will still remain in southern West Virginia and some in western Kentucky. Everywhere else the open shop will have full sway. Much water has passed over the wheel since the United States entered the world conflict.

The union and operators alike prefer to do business through the Fuel Administration and do not like to submit their differences to the so-called Labor Dictator, who bears the euphonious name of Felix Frankfurter. Mining men believe that they understand their own wants best. A meeting was held Thursday, May 16, to discuss the situation, Fuel Adminstrator Garfield, Advisers Peale and White, President Hayes, Vice President Lewis and Secretary Green being present.

The gradual unionization has done much to heal the differences between operators. The union and nonunion operators have always looked at one another somewhat askance. Propaganda suited to one field did not suit the other. Institutes found their members more or less at cross purposes. Coal associations spread with difficulty over the line which divided union from nonunion regions. Several companies were opposed to any entry into organizations doing business with the union. In fact they could not well associate themselves effectively with them.

The new labor conditions have had no little to do with the formation of the Central Pennsylvania Coal Producers Association with a membership representing mines producing 30,000,000 tons per annum. This has taken the place of the Coal Operators Association of Central Pennsylvania which represented about 8,000,000 tons of annual coal production and the Low Volatile Association, a newer body representing 20,000,000 tons.

Charles O'Neill, who has been vice president of the central Pennsylvania United Mine Workers, has been selected as general secretary of the Central Pennsylvania Coal Producers Association. O'Neill is a young man, but he has been quite influential in the union. He was for a number of years private secretary to Patrick Gilday, the president of District No. 2. When James Purcell succeeded Patrick Gilday, O'Neill became vice president of that district. For some months O'Neill has been in Washington taking the place of ex-president J. P. White, whenever the chief was touring the country for the Fuel Administration.

Reports about Liberty Bonds still come in and some will have to be deferred to the coming issue. In some instances there seems to have been some well-meant, but unfortunate, violence used by the bond sellers. It is just as well to avoid physical compulsion in the selling of bonds. If anyone thinks more should be subscribed let him buy more himself. If the Government had intended a forced levy; it would have provided for it by law. There are some arguments for the Government taking such a course; to many Australians, especially, this has seemed the best plan to adopt. However, till we make such a law there is no compulsion, and we certainly under no circumstances do well to haze or mistreat those who do not buy.

A more generous subscription would be a better way of meeting the issue, for the purchase of a big bond is a financial bargain for the investor. If he buys twice or three times as large a bond by that much is he the more benefited. When the verdict of the people is for compulsion, then let us have compulsion. At all times let us use alone methods that are lawful.

At a special convention held May 3 the Alabama mine workers ratified the new wage scale, details of which appear in our issue of Apr. 27, and on May 12 the Maryland mine workers approved of the working conditions already outlined in this review.

A 100 Per Cent. Liberty Loan Subscription

The Lehigh Valley Coal Co. has 17,496 employees. Out of this large number not one failed to subscribe in some amount to the third Liberty Loan. The average subscription was $57.01.

The employees of the company purchased $313,550 worth of the first Liberty Loan and $446,500 of the second, while the subscriptions to the third loan booked by the company for its employees lacked only $2500 of reaching one million. In other words $997,500 in third Liberty Loan bonds were sold by this company to its employees.

The men themselves took great interest in the loan and did much both individually and collectively to swell the number of bond buyers. Sometimes the arguments presented to the men who were reluctant in their purchases took forms bordering on the disorderly. "Slackers" were painted or placarded, and paraded through the villages where they resided.

In obstinate cases the mines were made so unpleasant for them that they either subscribed for a bond or quit work. So far as is known no actual violence or permanent injury was done either to person or property. In one instance the "patriots" conducted a miner to the brink of a reservoir and induced him to purchase a bond by threatening to "baptize him by immersion." Confronted with the certainty of a thorough ducking he finally consented to buy a bond. But after exacting this promise somebody suggested that he be given a ducking "just for luck," and he accordingly got his ducking, much to the delight of the crowd.

Throughout the campaign the coöperation between the local unions and the company officials has been close and cordial. Local union No. 458, at Maltby colliery, had $2000 which it decided to put into Liberty Bonds. The local banks got wind of the fact and several put in an application that the purchase be made through their institutions, but the union men wanted the subscription to be given through the company. Local union No. 1546, of Franklin colliery, with its investable fund somewhat depleted by a subscription of $1200 to the previous loan put $300 in the third issue, and gave the company credit for gaining the subscription. Local No. 1732 of Warrior Run colliery similarly invested $1000 in bonds.

Southern Anthracite Locals Also Buy Bonds

When the locals of the Lehigh-Coxe, the Delano and the Mahanoy & Shamokin divisions heard that the locals of the Lackawanna and Wyoming divisions were placing their subscriptions through the company they decided to do the same. In consequence Local No. 2848, of Sayre colliery, bought $500 worth through the company. Local No. 82, of Spring Brook colliery, took $100 worth, Local No. 961, of Spring Mountain colliery, $500 worth; Local No. 185, of Tomhicken colliery, $100 worth; Local No. 1381, of Lattimer strippings, $200 worth; Local No. 2631, of Oneida colliery, $100 worth and Local No. 2838, of Vulcan colliery, $250 worth, all through the Lehigh Valley Coal Company.

The company showed its appreciation ungrudgingly and in a little booklet it gives in greater detail the list we have just quoted in brief. The gracious act of the unions has strengthened the strong accord which is growing up between them and the company, and the good will is heightened by the Lehigh's recognition of the broad-minded attitude of its employees.

The company's record somewhat remodeled is as follows:

Division	1st Loan Amount	2d Loan Amount	3rd Loan Amount	3rd Loan Per Person
Treasurer and Controller's Dept., New York	$3,750	$3,100	$5,550	$132 14
Snow Shoe	8,850	12,400	22,000	60 27
Drifton Shops	10,050	6,350	15,900	58 45
Lackawanna Division	39,400	95,300	191,900	55 93
Mahanoy & Shamokin Division	75,300	42,800	175,200	55 58
Wyoming Division	56,600	118,700	211,650	55 30
Wyoming Valley Water Supply Co	950	200	3,150	55 26
Delano Division	34,850	28,850	106,550	55 20
Lehigh-Coxe Division	45,700	104,800	225,600	53 49

It will be seen that the one bituminous mine of the corporation led all the anthracite mines of the company in the generous size of its subscription.

EDITORIALS

Making Coke May Yet Be "Verboten"

NEW developments make new duties. In the coke industry manufacturing coke in "clamps" was the first development, and therefore the first offense against conservation. Only in China is that wasteful process still in operation. The beehive oven then followed as the ideal means of coke making, because it made better coke with less waste of fuel. Then came the Belgian oven, which saved labor, and the flue system, which supplied heat to boilers. Then, as what seemed a final economy, came the byproduct oven, or rather the series of byproduct ovens. To build anything else is now a crime punishable by unsuccessful operation and financial loss.

The article which we publish on page 912, "Bettering Coal by Heat and Pressure," awakens grave question as to whether we have any right to make coke at all. We are led to question whether instead of merely aiming badly we have been actually shooting at the wrong target altogether. This is almost certain if the experiments of Charles H. Smith are as revolutionary as they appear from the figures given in the article. However, it must be remembered that some mixtures of coal when coked in byproduct coke ovens give twice as much oil and tar as others and that the metallurgical value of carbocoal can only be determined by careful tests.

The following table is taken from Table II of Mr. Malcolmson's paper, but some of the information is consolidated and we think it reveals in consequence the value of the low-distillation process in a more striking manner. The last column shows the relative proportions of substances obtained by low-temperature distillation and by coking, the difference being most marked in the light oils. With carbocoal, according to the table, seven times as much oil is obtained as with byproduct coke.

RECOVERY OF LIQUID PRODUCTS PER SHORT TON OF RAW COAL PRODUCT

Product	Byproduct Coke Oven	Carbocoal	Relative Product
Light oil	0.27	1.583	5.863
Middle oil	0.44	3.326	7.559
Creosote oil	0.78	3.236	4.149
Heavy oil	1.26	11.365	9.020
Total oils	2.75	19.510	7.095
Pitch	4.66	10.190	2.187
Total products	7.41	29.700	4.008

The amount of carbocoal obtained is also quite high, and the ammonium sulphate produced 21 lb. per short ton of raw coal carbonized. Whether coke is to be a forbidden product or not is, of course, a question; but it looks as if a formidable rival had arisen. Our treatment of coal has always been ruthless. A body with such complex characteristics should have been handled with more circumspection.

In England low-temperature distillation of coal has made much progress, and it seems fully probable that the saving of byproducts will pay many times for the work involved, even should it be found that the improvement in the fuel was not enough in itself to pay the expenses of manufacture.

For the Worker, Work Is Patriotism

THERE is a complaint that some mine workers are of such a patriotic kidney that they take every opportunity to celebrate. It is hard to keep them at their work. A little celebration now and then does no one any harm. It puts vision into one's work and vim into one's labor, but it can easily be carried too far.

The purpose of celebration is to stimulate service, but with some the idea of celebration is divorced from the idea of labor and is associated only with pleasure or idleness. At Marion, Ill., a traveling war exhibit recently laid the mines idle. As coal is in great demand and the cars to move it are needed even more, it is incumbent on every man to load cars whenever opportunity is provided and to exhibit his patriotism on idle days when that is the only service he can render. Celebrating will not win any victories. If we do too much of it now, there will be nothing but defeat to commemorate when the war is over.

Naturalization vs. Americanization

IT IS interesting to note that the campaign about to be put into operation for the Americanization of foreigners is not laying any stress on the ceremony of naturalization. Too clearly we are learning that this legal status is often given to people who have never acquired the spirit of America. They have not our heritage of democracy; they have not our patient spirit which seeks to progress from precedent to precedent; they are suspicious of our institutions, and many of them are illiterate and so unable to enter into the purpose of our laws or to understand our business relations.

We do not need any more such Americans. We are surfeited with them now. If we give them citizens' rights, we shall find they control us and not we them. Let all those who are not pro-American remain foreigners, till they are brought to a new and better mind. We should be slow to welcome them to citizenship, for they do not welcome us to their fellowship.

The movement for Americanization, however, is based on broader, better grounds. If it were not we would do far better without it. The leaders of the movement do not scheme so much to make Americans as to make pro-Americans. The republic would be safe with 75 per cent. foreigners if that 75 per cent. was ardently pro-American and imbued with friendship toward the other 25 per cent.; but if the proportions were reversed and we had 25 per cent. naturalized foreigners whose only affiliation with America arose from an oath taken under economic or physical pressure, or even under earnest persuasion, the republic would be in considerable danger of disruption.

Americanization is a slower process than what we speciously term "naturalization." We can "naturalize" in an hour. Americanization takes some months. We can "naturalize" with a little violence, but it takes the rarest

sympathy and tact to Americanize. But like all things expensive and slowly acquired, Americanization is worth all that it costs in time, money and trouble.

The enemy alien is just now peculiarly susceptible to Americanization, especially if he is not of Teutonic but of Magyar, Slovak, Czech or Serb stock. He knows that in most countries he would be treated with far greater severity. If he is reasonable he realizes that he is being used with exemplary indulgence. He is ready therefore to become pro-American if only a little impulse is given. He cannot become an American. Few care much that he should. If we have his heart and his hand who cares if we are deprived of his ballot?

As for the alien from an allied nation, we could not find a better time to bring him under the spell of our affection whether he be Italian, Russian, Irish or British. But we do not do well to ask him too sedulously to seal that affection with a bond, nor will we make headway with him if we too suspiciously urge upon him on every available occasion that in the words of Charles Dickens: "Codlin's your friend and not Short."

Our readers will pardon the following simile: The care of a child passes to a foster mother, a mother whose care is perhaps unremitting, but whose justifiable pride refuses to be hidden. She tries to ingratiate herself with her protégé by suggestions that his former mother was not as generous, sympathetic and beneficent as is his foster mother. The suggestion is not tactful even when true.

Unfortunately, we do not always see Americanization in that light. We are continually asking for pledges and persistently urgent in the question "Don't you like America better than Transpontiana?" It suffices if we punish disaffection and disloyalty. Positive declarations of affection if obtained by pressure are apt to foster the very spirit we seek to quell. Patriotism is an affection of the heart; it has been the great offense of the Germans that they tried to plant that delicate flower in alien soil by dint of forced naturalization and repressive measures.

Lengthening the Worker's Stride

IN SOME companies the number of men who subscribed for the Third Liberty Loan formed a large percentage of the whole force employed, but it still seems possible to improve the record a little. If the 40,000,000 wage earners in the United States buy a $50 bond, the amount raised is only $2,000,000,000, about one-tenth of what we shall require annually when we get our war stride and half what we are raising by taxation. If, as was the case in the Third Liberty Loan, only 17,000,000 subscribe, the amount raised by a $50 subscription would be only $850,000,000, quite a little less than a billion.

For this reason it seems that the size of the taking has not been sufficiently emphasized. In some companies the subscription came so close to $50 per employee, though all subscribed, that assuming that no one bought more than $100 worth of bonds the number of men buying two bonds apiece cannot have been more than 6 or 10 per cent. of those buying $50. It seems therefore that the canvass was conducted on the supposition that $50 was all that a workman could or should be expected to take.

There are not a few stories told of men who came to the boss and asked to buy a bond. The employer offered to sell him a $50 obligation and the workman, not satisfied, finally demanded one of a $1000 denomination. In one case a boy turned in his father's order, and when the manager was informed he summoned the old man to the office, bent on explaining to the foolish fellow that he could never pay for a $1500 bond by installments from his slim pay. The workman however closed the argument by producing from the lining of his coat a roll of bills which was more than sufficient to buy all the bonds his boy had contracted for.

The operator needs a little more faith. He does not yet know the splendid spirit of the men whom he commands industrially. Unfortunately he too often comes in contact with the mere wastrels of the mines, but the main body of the men have the interests of their family, the country and the company at heart. Loyalty is a virtue they have in abundance. The operator has had many a time to fear that spirit of loyalty when it was used against him. It is now directed in favor of national unity and victory, and the miner is showing how powerful its appeal obsesses him, and if he is approached to buy in hundreds of dollars, that is how he will buy; for he never was a quitter.

Give Till It Hurts?

ONE of our national organizations for war relief has urged that we give till it hurts. But giving doesn't hurt. If you doubt that statement just look at the givers. They are the happiest, heartiest, liveliest and most desired of all our friends. Hurt? They are not hurt. The crabbed soul who never gave a cent, or gave it grudgingly and of necessity, is the man who is hurt; and that injury is vital. It has attacked the very soul of the man, and it can go no deeper. Slowly, all that was best in him has been destroyed. It is not giving, it is refraining from gifts that hurts.

The American Red Cross is making a drive for $100,000,000 for war-relief work. The men who are making the call—we purposely do not term it an appeal—the men who are making the call are business men, and they ask a generous people for generous gifts. They are in touch with the American heart, and they know it is not the shriveled organ of a curmudgeon. They do not come to us each month with a new appeal, but ask us for enough to keep them going handsomely for some months. And the American people, capitalists and workingmen, will not deny them.

No body is all heart. The human heart is but a part of the human body. Similarly, the whole body of American people is not all heart. There are a few among us who do most of the giving. From them the American nation receives its glory and the American flag its luster. They must give, not a fair share, but an abundant share. The factor of safety for them must be not one, but ten, or this great donation will not be fully subscribed.

Therefore give—not till it hurts—but till it helps, till an allopathic dose of giving clears the foul humors from your heart and brain, and leaves you convalescent from your surfeit of self-indulgence. By thus giving you can help our boys and at the same time help our land to beam with the happy smile of the generous giver.

DISCUSSION BY READERS

Men in Blind Alleys

Letter No. 3—I agree wholly with the ideas advanced by "Lumen," *Coal Age*, Apr. 6, p. 644, in regard to men who continue to live in "blind alleys."

In my opinion, every man is the architect of his own fortune. When one is content to live in a blind alley he is in a rut. Such a man makes no effort to get out and travel a new road or explore a new country, so to speak. I want to indorse the sentiment already expressed, that every worker in this country, today, must study the theory of his work. It is a great mistake for a young man to be so indifferent to his future welfare that he neglects to study the principles underlying his occupation.

Whether a man works in an office or in a mine, he has the same chance to advance and gain a higher position, from month to month and year to year. Employers are not slow to recognize that the men who study do better work, make fewer mistakes, and the cost of production is reduced, because more work is accomplished in the same time. This is true of all work outside or inside of the mine.

Let me say, in closing, that to every young man there comes the opportunity to climb. The ladder is before him, but he must mount it step by step before he can gain the top.

C. McMANIMAN.

Rawdon, Quebec, Canada.

Transportation of Coal by Canals

Letter No. 1—I was deeply interested in reading the article of W. W. Wotherspoon, state superintendent of public works, entitled "The Canal as a Carrier of Coal," which appeared in *Coal Age*, Mar. 2, p. 402.

The author of the paper says, "It is believed coal may be profitably transported in large volume via the canal at a rate of two mills per ton-mile."; but he does not tell how he arrives at that figure or what such estimated cost includes. It would be of interest to know if the expense of returning the empty cars to the mines is included.

In order to reach a right conclusion, one should know what the actual cost of transportation is, including maintenance and repair of the canal, and the locks and dams, and what is needed to cover interest and sinking fund charges on the bonds issued by the state to pay for the construction. If this two-mill rate does not include all of these items, then the public, or at least the taxpayers of New York State, indirectly pay a large part of the transportation cost of the coal.

That this was feared by the taxpayers of the farmer class is shown by an editorial in a recent number of the *American Agriculturist*, which says, "it has all worked out as the farmers of New York State feared some years ago when they voted so heavily against the bond issue. We showed that the canal, being mainly of national concern, should be improved by the nation. But the cities of the state overrode the farmers and the money was voted, the cost advanced 50 per cent. and the farmers' property will now be taxed for years to come, to pay heavily for the most colossal mistake ever foisted upon the taxpayers of the Empire State."

Kindly let me suggest to Mr. Wotherspoon that if the two-mill rate, per ton-mile, does not include the factors I have mentioned and the cost of carrying, the coal must then be paid for by the public, in the shape of taxes to cover these items, it would be of interest to have him revise his figures so as to include them and make the results public.

I fully believe that the public and the taxpayers of New York State, are entitled to know what is the *real total transportation cost* by canal, as well as the cost of the operation of the boats. With regard to this phase of the question, the following extracts from the Final Reports of the National Waterways Commission are enlightening:

> The amount of traffic available with a given equipment affects the cost of transportation by water in much the same way as it does the cost by rail. In both cases there are certain fixed costs on which interest must be paid, regardless of the amount of traffic moved, so that an increase of business, with the same equipment, results in a rapid decrease in cost per unit.
>
> When the waterway is a canal and is intended to be self-supporting, the analogy is perfect; but the same principle should apply to expenditures for the improvement of rivers. In determining the cost of transportation by water, each ton should be charged with its proportion of the cost of the improvement, even though in actual practice the expense is borne by the Government.

Cost of Transportation on the Erie Canal

The report then goes on to say regarding transportation rates and costs on the old Erie Canal:

> The average rate, per ton-mile, on the Erie Canal, is about 2.45 mills. Comparing this with the average freight rate, it is frequently stated that the cost on this canal is about one-third of that by rail. But no such exact comparisons can be made, for the reason that the rates compared do not include the same elements of cost. . . .
>
> The average cost of transportation on the Erie Canal includes only the bare cost of conveying the traffic, plus a small return on the equipment used. It contributes nothing for the maintenance, nor does it make any return on the capital expended for the construction and enlargement of the Canal. Both these expenses are paid by the State of New York.
>
> It has been conservatively estimated that if the canal traffic was charged with a toll sufficient to cover these additional expenses the rate, per ton-mile, would amount to 8.61 mills. The average rate for similar commodities, especially on the railroads in New York State, is probably not more than five or six mills, per ton-mile. . . .
>
> Any comparison between cost of transportation by rail and by water will be of value only when the two rates include similar elements of cost. Few such comparisons have ever been made.

The statements here quoted were made with reference to the old Erie Canal, which, according to the authority

of A. Barton Hepburn, in his book "Artificial Waterways and Commercial Development," cost $49,591,853.

If the figures given above, showing a cost of 8.61 mills, per ton-mile, on the old canal, which cost in round numbers fifty million dollars, are correct, how can the new canal, costing over three times that of the old, be operated at a rate less than one-quarter the cost, per ton-mile, on the old canal, when all the proper charges entering into the cost of operation are taken into account?

Can it be denied that if coal can be transported on the new canal at two mills, per ton-mile, with a profit to the boat owner, it is because the taxpayers of New York State pay all the other items mentioned above that go to make up the real total cost of operation? Would not this be equally true, even if the canal had been constructed by the National Government, as suggested by the editor of the *American Agriculturist*, except that all the transportation cost, over the actual cost of the operation of the boats, would be borne by the public at large, instead of the taxpayers of New York State?

Pittsburgh, Penn. W. G. WILKINS.

Mining Equipment

Letter No. 4—The letter of P. K. Howard, *Coal Age*, Apr. 13, p. 710, drawing attention to the importance of providing better axles for mine cars, interested me greatly, because for years I have felt that mine superintendents were restricting the capacity of their mines by the use of low-grade equipment.

Not being a technical man, I frequently fail to understand the details of the heat treatment of steel axles, such as advocated by Mr. Howard. But, as a stockholder in several important mining operations, I constantly visit the coal mines, and have often been impressed by the seeming loss in efficiency and the comparative short life of the average mine equipment.

This is largely due to the low-grade materials used and the fact that many mining companies, in buying equipment, hold the manufacturer to their own specifications. In many cases the manufacturer, by reason of his better knowledge of the proposition, is in a position to furnish much superior equipment at the same price if he was allowed to follow the methods and plans that his experience has shown him to be the best.

USE OF LOW-GRADE MATERIAL IN MINE EQUIPMENT

My impression gained from personal observation and by talking to practical mining men, is that the general run of equipment used in coal mines today is of a lower grade than that used in any other industry that is as important as that of coal mining. Every year sees tremendous strides in the improvement of machine tools. Careful redesigning, based upon experiment and continued research, suggest improvements in the kind and quality of material used, all of which goes to speed up the work produced by machine tools and makes it possible to turn out better tools at a lower cost for labor and there is less depreciation of equipment.

In the average coal mine of today, however, one can find mine cars that are essentially the same in design and materials as those used in the earlier days. But, as Mr. Howard says, this state of unprogressiveness is not the fault of the mine-car manufacturers, who are frequently in a position to supply a higher grade of equipment, but are forced by the demands of the operators to furnish cars of inferior material and design, at a low price.

DESIRE TO REDUCE FIRST COST

It is my honest opinion that the men who are responsible for the purchase of new equipment, are giving too much of their attention to the first cost of the mine cars they require, and disregard the ultimate cost, which is caused by the labor and materials used in making frequent repairs, the time lost when cars are in the shop and the depreciation charges, which are abnormally high on short-lived equipment. Any man who has ever tried it knows that one good suit of clothes will outwear three cheap suits and give much greater satisfaction throughout its useful life.

I am glad to learn from Mr. Howard's letter that heat-treated axles are being used by some of the far-sighted mine opertors, and believe that the coal-mining industry will benefit greatly by the constant improvement in the design and material entering into the construction of mine cars. Any results that practical mining men have obtained from the use of heat-treated axles and other improvements in car designs would certainly be of benefit to other mining men and all should come forward with their experiences.

An authorative article by an expert on steel for mine-car bodies and running gear could not fail to be of value to men who realize that their mining equipment should be improved, but who hesitate to change from their old style of equipment, because they do not know the possibilities of superior material and modern design.

Washington, D. C. MAVERETT ASHLEY.

Letter No. 5—I agree thoroughly with "Progressive" when he urges, in his letter, *Coal Age*, Mar. 9, p. 468, that coal operators who have bought and used certain types of mine equipment should discuss their merits and demerits for the benefit of the industry. The experiences of users must serve as a guide to prospective buyers, and this applies to all classes of mining equipment. The discussion of the actual performance of equipment it is desired to purchase is indeed most valuable to the prospective buyer.

Coal-mining executives, as a rule, however, decline to discuss the benefits received from the use of a new machine. *Coal Age* has, from time to time, called attention to the fact that the columns of the paper are always open for a discussion of this kind; but mining people have not generally availed themselves of this offer.

Letter No. 2, which appeared Apr. 13, p. 710, calls attention to the fact that coal operators hesitate to express their views for fear of giving away valuable information. Let me say that any manufacturer of worthy equipment should welcome a full and free discussion of the worth of such equipment when written by users.

Since this is not done, however, it remains for manufacturers to resort to advertising and personal solicitation in order to reach the probable prospect. Letters of endorsement substantiate the facts set forth in this way, and they are worthy of the most serious consideration on the part of people contemplating the purchase of the

equipment or product described. Such a letter is not given as a result of one or two days' trial; but, instead, after the equipment or product has undergone a severe trial and the user is convinced of its real worth.

It is to be hoped that operating officials will relate their experiences with mining equipment for the benefit of those who contemplate purchasing. Particularly is this true of roller-bearing mine cars and storage-battery locomotives.

In the same issue of *Coal Age*, page 710, P. K. Howard, speaking of mine equipment, discusses the use of heat-treated axles on mine cars. From my own observation, the use of heat-treated axles on mine cars has never been considered by the coal operators, in the bituminous fields of Pennsylvania, West Virginia, Ohio and Maryland. However, the adoption of 5- and 6-ton cars to take the place of the 1- and 2-ton cars formerly used, may make it necessary to use heat-treated axles, on these larger cars. But, their use can only be brought about as the result of education on the part of advocates of this type of axle.

Cars holding 6 tons of coal are used in the anthracite region of Pennsylvania, and these are subjected to severe service; whereas the cars used in the bituminous fields rarely hold more than 4 tons of coal, though they too are subjected to severe service.

I agree with Mr. Howard when he states that a discussion of this subject will prove of untold interest to coal operators. For myself, I must profess ignorance on the subject of heat-treated axles for use on mine cars and, for that reason, hope that someone will furnish light and illustrate the subject with sketches or photographs. K. J. WALTERS.

Pittsburgh, Penn.

Gathering Motors

Letter No. 2—In these days of national crisis, the mine operator and management are confronted with the ever-increasing cry, "Produce more coal." Every practical mining man knows that the installation of a successful haulage system, in a mine, goes a long way toward meeting the demand of increased production.

In this connection, I have been greatly interested in the several articles that have appeared in recent issues of *Coal Age*, regarding the storage-battery locomotive as being the best adapted to the gathering of coal at the working face. The merit of a mechanical haulage system over the old fashioned practice of mule haulage is freely admitted by practically all mining men of experience who have made any study of the haulage of coal in mines.

However, while admitting the advantages of mechanical haulage over mule haulage, I am hardly prepared to go as far as some claim, in respect to the comparative merits of the storage-battery locomotive and the trolley system of haulage. To my mind, each of these systems has its peculiar adaptation to different mining conditions, and they can hardly be regarded as belonging to the same class.

My experience convinces me that the trolley system of haulage is well adapted for use on the main haulage roads in mines, while the storage-battery locomotive is particularly fitted for the gathering of coal from the working face and placing it on the inside parting, in readiness to be hauled out of the mine.

The work of gathering was formerly done by mules, but so successful has been the use of the storage-battery locomotive at the face that it can be predicted, almost with certainty, that the mine mule will soon be relieved of his burdensome life in the mine, and permitted to pass the remainder of his days in a more congenial atmosphere.

Storage-Battery Locomotives Used on Main Haulage Roads

I do not wish to be understood as restricting the storage-battery locomotive wholly to the work of gathering cars at the face. In my opinion, in a large number of instances, this type of locomotive can be used with decided success on main haulage roads. The operation of the machine is so simple as to require no mechanical ability worthy of mention. It can be much injured by neglect and carelessness; but, with proper care in its operation and with suitable attention to the batteries and an occasional inspection of all working parts, the cost of upkeep will be reduced to a minimum and the efficiency of the machine maintained at a maximum.

In a number of mines recently visited, I have been greatly impressed with the working efficiency of this type of motor. A number of those observed I found were built by the Ironton Engine Co., of Ironton, Ohio, and it gave me pleasure to note the ease with which they were handled and how much they increased the general efficiency in the production of coal. SPECTATOR.

Meyersdale, Penn.

Letter No. 3—I read with much interest the letter by "Motorman" of Herrin, Ill., *Coal Age*, Apr. 27, p. 800, and desire to offer a few comments on his suggestion recommending the combination battery-and-trolley locomotive as being desirable for use in the mines. The several letters that have appeared recently in *Coal Age*, regarding locomotive haulage in mines have been very good and practical. They should prove a great help to coal operators and mine foremen, in choosing the system of haulage best adapted to their needs.

My personal opinion in regard to the combination battery-and-trolley locomotive, recommended by "Motorman," is directly opposed to that expressed in his letter. I have investigated a number of designs of this type of locomotive and observed its performance under different conditions in mines, and conclude that the combined type is not practical.

Why Combined Battery and Trolley Operation Is Not Practicable

In the first place, a locomotive operated by trolley or battery must have sufficient motor capacity for the given weight. This capacity, we will say, is, at least, 10 hp. per ton, in order to utilize the full tractive effort of the machine and avoid the slipping of the wheels on the rails. But, it is not possible to find a storage-battery locomotive with this capacity of motor, whether the machine is equipped with a pole or not.

My claim is, therefore, that the motor capacity of a storage-battery locomotive is not suitable for use on a trolley system, and such a machine cannot be adapted to that work by simply equipping the machine with a trolley pole. If the motors are made efficient for bat-

tery work, they are not suitable for good operation on trolley work; and if they are made of suitable capacity for operation by trolley, they will prove very inefficient for battery work.

Again, the combination trolley-and-battery locomotive is more complicated than the trolley machine, and would require to be looked after by the mine electrician. Also, the machine is more susceptible of abuse by the motorman, because of the battery being overcharged or discharged and run at exceedingly high temperatures.

Essential Features of Battery Locomotives

The best form of storage-battery locomotive, for gathering purposes, therefore, is one whose motors are designed for storage-battery work, having a low internal resistance and low iron loss. The machine should be designed to give equal efficiency at one-quarter full load as at full load. In other words, the losses in the motor should be so balanced that the motor will be equally efficient when hauling light or heavy loads.

The battery should have sufficient capacity to complete the necessary work of a full shift, so that all the charging, filling, cleaning, etc., can be accomplished at the battery-charging station where proper facilities are provided for that purpose, including switchboard and other measuring instruments.

While there are some practical installations of combination battery-and-trolley locomotives that are highly successful, such installations are not generally recommended because the simplest possible combination of mechanical and electrical parts, as we all know, are required in coal-mining conditions. In this connection, allow me to present the following little burlesque, which was written by a friend of mine when these locomotives first appeared on the market.

Columbus, Ohio Edison Marconi Ampere.

The Wonder Mfg. Co.
Cincinnati, Ohio
Gentlemen:—

I got your letter askin did the new combinashun troley and battery locomotive run. It does. When we got it we put it on the new circular track in no six entry and Bill Stevens which is our best motorman wanted to show off and he got on the locomotive and there is so many little hickies and dewdads on the durn buss an Bill evidently didnt know as much as he thought he did and he got bawled up and must have jimmied something and jammed the rong lever for the locomotive run steady through 19 shifts or nearly six days the track is circular as i sed before and when the battery run out the durn thing hit the troley wire and charged up the battery again and the locomotive stept along a little livelier and we were afraid we would have to shoot Bill to keep him from starving to deth.

Some ginnie in the power house tried to shut the power off and he hit the rong switch and we had forth of july and the last daze of pompey simultaneously and to oncet. We gobbed the ginnie. The locomotive kept on goin til it run off the track and Bill went up in the air and came down on the hot resistance burning his pantz an swore awful. When we got the locomotive in the charging shed say Bo you ought to have saw that battery it looked like a piece of limburger cheese what some one had carried in their hip pocket in hot weather it was some mess believe me. We had volts and kilowatts scattered around all over the place to say nothing of ohms. The locomotive is not what you call a success at least not on no circular tracks with a green motorman.

Yours truly,
Juan Hrdlika Pit Boss.
Circle City, Skiddoo County, Colo.

Selection of Mine Timber

Letter No. 1—Since reading the inquiry that appeared in *Coal Age* [Dec. 29, p. 1113], regarding the size and kind of timber required in mines, I have become much interested in the selection of timber that is best adapted to mining conditions, in respect to both the strength and life of the timber.

As is well known, the timber required in mines for different purposes, such as props, crossbars, caps, track-ties and lagging, ranges from mere saplings to large logs varying from 20 in. to 2 ft. in diameter. In the selection of mine timber regard must be had to the use intended, as all timber is not equally strong or equally durable under the severe conditions to which it is subjected in mining.

Timber that is not properly seasoned or dried before being taken into the mine may develop dry rot or be rapidly destroyed by fungus growth or worms. For mining use it should be cut in the winter season, say from the last of November to the first of March. During these three months of the year the sap has practically drained from the wood, and timber cut then is more readily seasoned for use.

When the trees are felled they should be cut at once into lengths suitable for use as props, crossbars, ties and lagging, while all waste ends should be split for cap-pieces to avoid undue waste. The cut timber should be stacked on end, in piles, to aid the process of drying, and the brush piled and burned.

In general it may be stated that the best timber is to be found on high ground where its slower growth develops greater strength in the wood. The weaker timbers, for the most part, grow on low ground where the moisture affords a more rapid growth.

The principal woods used in mining are the following: Oak, hickory, pine, cedar, spruce, tamarack, hemlock and cedar. These make the best mine timber, because they possess greater relative strength and durability than most of the other woods found in the states and Canada. Probably the strongest and most durable of the timbers named are the oak and hickory, which are commonly classed as hard wood. Allow me, now, to briefly summarize the character of each kind of timber named, as follows:

Character and Qualities of Mine Timbers

Oak—There are a number of different kinds of oak, as white oak, red oak, black oak, etc. These differ mostly in color, texture and grain. The white oak, so largely used in mining, is a heavy, hard and strong wood of a close, straight grain. It is used chiefly on main airways and haulage roads where timber of greater strength and durability is required. The red and the black oak are both softer and more porous than the white oak but still make excellent mine timber.

Hickory—This, also, is a heavy, hard and tough wood. Good, sound hickory is stronger than oak. The wood, however, is not durable, and its use in mines is chiefly limited to the timbering of rooms where the life of the timber is not so important as on the haulage roads and airways.

Pine—This is a good, light, soft wood that is easily handled and cut for use in the mine. It is straight

grained, comparatively free from knots and fairly durable. It is much used in lining shafts, building doors, air bridges and brattices in mines. When well seasoned it makes good prop timber and cap-pieces.

Spruce—Like pine, this is a soft, straight-grained light wood that is useful in the mine. It is slightly less durable than pine timber, being subject to dry rot, which may be largely prevented by chemical treatment. The variety known as white spruce is remarkable for its clear satiny appearance from the bark to the center. The spruce tree has many branches, which make the wood knotty and of inferior strength.

Tamarack—This is one of the most durable of all mine timbers. It is frequently found in the vicinity of lakes on low or middle land. In appearance it resembles the spruce with the exception only that, unlike trees of this class, it sheds its leaves in winter. The sapwood is white for about an inch in depth, while the remaining heartwood is a dark red in color. Tamarack makes an excellent mine timber. Its strength is almost equal to that of oak, and it breaks more slowly.

Hemlock—This is a soft but brittle wood of a coarse, uneven grain. It is light but not durable. When used in mines it is chiefly employed for props in rooms and for cap-pieces. Because it breaks quickly without warning, it is of no value for crossbeams or collars.

Cedar—This is a favorite wood in mining, because it is soft, light, with a generally fine texture, straight-grained and durable. The best cedar is not subject to dry rot. This variety is known as mountain cedar and is preferable to the growth found in valleys or swamps, which has a coarser grain and develops dry rot at the center. Valley cedar, however, is much used in room-work and in longwall mining, because it is easily worked to size.

Other soft woods used to a limited extent are the beech, chestnut, elm, locust, poplar and walnut. With the exception of the locust and walnut, these woods are much too soft and lack the necessary durability.

Rawdon, Que., Canada. C. McMANIMAN.

Mass Education Needed

Letter No. 3—There comes a time in the history of every nation when it becomes necessary to take account of its many activities, in order to ascertain its stability as a going concern, estimate on its rate of progress and determine what means of improvement there are in respect to future operations. It appears to me that such a time has arrived in respect to the education of men employed in the mining of coal in this country.

In the past, mining education here, has been confined very largely to the training of colliery officials. As a rule, little attention has been given to the education and training of the general body of workers on whom the safety of the mines so largely depends. Every boy and man employed underground and ignorant of the many causes of danger is a menace to safety—a state of things that ought not to be allowed to continue.

No system of education is complete that does not provide for the training of young workers to appreciate the dangers of their occupations and their individual responsibilities. The educational ladder, so to speak, must be so complete as to permit any intelligent man to gradually mount, step by step, until he has reached the top.

Mining classes should be in the hands of capable and sympathetic teachers, who should be supplied with the necessary books and apparatus to enable them to teach the underlying principles and make the course of study a practical one. The work should receive the hearty coöperation and assistance of the mine officials who should realize the increased efficiency and safety to be derved from this source.

When proper attention is given to the matter of education, there should be no difficulty experienced in securing the attendance of the majority of young men, in any mining district. The enthusiasm aroused by those attending the first session should be a strong factor in bringing others into the classes, which should include the study of English, drawing, practical mathematics, physics and chemistry.

Although the movement to educate the great body of mine workers is now widely established in the larger mining towns and districts, many of the smaller camps are without these advantages. It is a mistake to attempt to teach experimental physics or practical chemistry relating to mining, by means of a piece of chalk and a blackboard, as is still frequently done, with the result that interest lags and little good is accomplished.

Students Should Be Taught How to Perform

The teaching of science should be closely associated with the actual doing of what is taught. A man may know many things wthout beng able to do one of them. The mathematics taught ought to be such as can be applied to the working of practical mining problems and this should constitute the method employed in teaching. The same applies to drawing.

When the student has been taught how to handle his instruments, and the difference between a plan and an elevation or cross-section has been explained, and the purpose of each made clear, he should be drilled in acquiring accuracy and speed, in making simple drawings of such objects as he is familiar with in his work. In other words, the course should form a part of his mining training and not considered as a preliminary study to enable the student to gain a knowledge of things without performing the work.

Were this scheme of practical training generally adopted, not only would the mines be safer, but the work would be more efficiently done and the mining of coal would be a better investment. In my opinion, mine officials make a mistake in demanding the long hours the miner must work underground. Better work would be done in less time if a portion of these long hours were to be devoted to the training of men in practical work. Where a man is compelled to work from 12 to 13 hours a day, he has little ambition or time for study and training.

Observation would seem to show that there is far less interest being taken by many mine officials in the anthracite region today than was exhibited a few years ago. Some of these men are paid a lower compensation than the men who work under them, and this may be one cause for their discouragement and lack of interest in the work of education among their men.

Plymouth, Penn. JOSEPH R. THOMAS

INQUIRIES OF GENERAL INTEREST

Chart for Estimating Change in Declination of Sun

Kindly allow me to refer to the interesting chart given in the article describing the Ross meridiograph, *Coal Age*, Apr. 20, p. 732. The chart appeals to me as somewhat better than the one with which those who have used the meridiograph are familiar, and I am anxious to know how it is constructed.

It has occurred to me that the average engineer does not cover more than, say 10 deg. of longitude, and many are limited to the half of that. My idea would be to construct a chart on a larger scale arranged to read minutes of longitude and half-hours of time, besides drawing the declination lines for each degree or half-degree of declination. Kindly explain. H. M. K.

———, Penn.

The chart referred to by this correspondent is a simple diagram for estimating the change in apparent declination of the sun, for any longitude east or west of Greenwich and for any local time of observation, between the hours 9 a.m. and 4 p.m. The estimated change is that which has taken place in the sun, counting from Greenwich noon to the local time of observation.

By way of explaining the construction of the chart, attention is first drawn to the fact that the rate of change in the sun's declination varies with the angle that the plane of the ecliptic makes with that of the equator. A reference to the Ephemeris shows that the declination changes 23.7 min. in 24 hours, at the equinoxes, while at the solstices the change, in the same time, is practically zero.

As there is no appreciable error in assuming that the change in declination is uniform for 12 hours, a diagram is constructed on a pair of coördinate axes, by laying off the change, in minutes, for each degree of declination, as abscissas; and the corresponding time, in hours, as ordinates. This will explain how all the declination diagonals start from the origin of coördinates at the lower left-hand corner of the diagram. For the sake of convenience only, the vertical line in the diagram, representing the meridian of Greenwich, is marked 11.85, which is the maximum change in 12 hours, and the diagonal for a zero declination is drawn to that point. The scale of minutes is then divided accordingly.

The next step, after marking off this scale, is to find from the Ephemeris the amount of change in 24 hours, for any desired degree of declination, by subtracting two consecutive declinations embracing that degree, as given in the table. One-half this difference is the change for 12 hours, and the diagonal for that declination is then drawn from the origin of coördinates to the point, in the declination scale, corresponding to this change. In like manner the change in 12 hours for other declinations is found and the diagonals drawn.

For example: To find the change in 12 hours for a declination of 10 deg. Referring to the Ephemeris for 1917, which can be used with no appreciable error for a period of 10 or 15 years, the declination for Feb. 23 is given as 9 deg. 55.8 min., while that for Feb. 22 is 10 deg. 17.7 min. The difference between these two declinations (21.9 min.), divided by 2, gives the change in 12 hours, for that angle of the ecliptic as 10.95 minutes.

The next step in the procedure is to determine the time that has elapsed from Greenwich noon to the local time of observation. Clearly, this difference in time is made up of two parts: (1) The difference between local noon and Greenwich noon, which is 1 hour for each 15 deg. of longitude; (2) the time of observation, before or after noon. Hence, each hour diagonal must start from the corresponding hour on the meridian of Greenwich and incline upward at the rate of 1 hour for each 15 deg. of longitude.

From this construction it is clear that following the hour diagonal corresponding to the local time of observation to its intersection with the given longitude gives the proportional rise vertically above the datum line or horizontal axis and divides the declination diagonals, each in the ratio of the estimated difference of time to the full 12 hours of the declination scale.

Most engineers will agree that there is no advantage to be gained by constructing a local chart to cover, say 10 deg. of longitude. This can be done, if desired, by following the same method of procedure as that just explained. The chief difficulty encountered in the undertaking is the length of the chart vertically.

For example, to enable the accurate reading of the chart it is necessary that the hour diagonals cross the horizontal lines at an angle that will clearly define their intersection, say 25 or 30 deg. The difference of time for 10 deg. of longitude is two-thirds of an hour. Then, if the hour diagonals incline at an angle whose tangent is 0.5, two-thirds of an hour, on the vertical axis, will be one-half the length of the horizontal scale; or 1 hour on the vertical scale will be three-fourths of the width of the chart.

Starting the 9 a.m. diagonal from the lower right-hand corner of the diagram, and terminating the 4 p.m. diagonal in the upper left-hand corner, will make the height of the chart ($7\frac{2}{3}$ hours), $7\frac{2}{3} \times \frac{3}{4} = 5\frac{3}{4}$, or nearly six times its width. This, again, would make the declination lines present too close a parallelism with the vertical lines and make the accurate reading of the scale difficult.

When one considers that the maximum change in declination is only, approximately, 1 min. of arc in an hour; and the difference of time is 1 hour for 15 deg. of longitude, it is clear that there is no need for a closer approximation than the original chart affords.

EXAMINATION QUESTIONS

Bituminous (Penn.) Examination, Apr. 11-12, 1918

(Selected Questions)

Ques.—State where and under what conditions it is unlawful to use an open light in the mine.

Ans.—The bituminous mine law of Pennsylvania (Art. 10, Sec. 1) prohibits the use of open lights "in any entry, airway, travelingway, room or any other working place where explosive gas is being generated in such quantity as can be detected by an approved safety lamp; also in pillar workings where a sudden inflow of explosive gas is likely to be encountered.... [Also,] in all working places, roadways, or other portions of the mine through which explosive gas might be carried in the air current, in quantities indicating danger."

The same section further authorizes the mine inspectors, with the approval of the court, to prohibit the use of open lights in any section of the mine that, in their judgment, should be worked exclusively with locked safety lamps. Sec. 3 prohibits the use of open lights in the return air current of any portion of a mine where locked safety lamps are used.

Ques.—Are regulators necessary in the ventilating of coal mines, and, if so, where should they be placed, and why?

Ans.—The use of regulators is necessary, in the ventilation of any section of a mine, where more or less air is required than the quantity that is provided by the natural division of the current. Regulators must be placed in those splits that offer less resistance than what is required to provide the desired distribution of the air. As far as practicable, all regulators should be located either on the back entry or at the mouth of the split, but in such a position that they will not obstruct the haulage roads in the mine.

Ques.—After you, as fireboss, had completed your examination of a mine, how would others know you had examined all the working places? If you discovered danger, how and where would you place your danger signals?

Ans.—The mine law requires that the fireboss shall mark the date on the face and side of every working place examined, as evidence that he has performed his duty. The law further requires the fireboss to enter, with ink, the results of his examination, in a book kept for that purpose. This entry must be made immediately after the examination is completed and must show the time taken in making the examination and the nature and location of any dangers that may have been discovered. The fireboss must place a suitable danger signal across the entrance to any place where danger is discovered, and remove the danger sign from the mine entrance, showing that it is safe for men to enter for work.

Ques.—What instructions would you give workmen in regard to their safety, and what action would you take to see that your instructions were carried out? Explain fully.

Ans.—Every workman should be made to understand that he is personally responsible in the matter of securing his own safety and must report promptly any danger that he may discover in his own or any other working place. He must be instructed to withdraw from his place should danger develop while he is at work. He must report the same to the mine foreman or his assistant. The workmen should be instructed to obey promptly what orders are given them in regard to the timbering of their places or the mining of the coal. When intrusted with safety lamps, workmen should be given full instructions in regard to their use. The mine foreman and his assistant should visit the working places frequently enough to ascertain that their orders are obeyed.

Ques.—What is the pressure of one atmosphere equivalent to, in pounds per square foot?

Ans.—The normal or average atmospheric pressure, at sea level, is commonly taken as 14.696 lb. per sq.in. This is what is termed "one atmosphere," at sea level, and is equivalent to $14.696 \times 144 = 2116.224$ lb. per sq.ft. Or, taking the normal sea-level pressure as 14.7 lb. per sq.in., this is equivalent to $14.7 \times 144 = 2116.8$ lb. per sq.ft.

Ques.—What is the weight of a cubic foot of air, at a temperature of 60 deg., and a barometer reading of 29.5 in.?

Ans.—The weight of a cubic foot of dry air at a temperature t, in degrees Fahr., and a barometer B, expressed in inches, is calculated by the formula

$$w = \frac{1.3273B}{460 + t} = \frac{1.3273 \times 29.5}{460 + 60} = 0.0753\ lb.$$

Ques.—An airway 5 x 9 ft., 1200 ft. long, is passing 15,000 cu.ft. of air and gas per minute. The mixture contains one-half air and one-half gas. If one-half more air were added, what would then be the velocity of the current, in feet per second, and what would your lighted safety lamp indicate if placed in the current?

Ans.—The sectional area of this airway is $5 \times 9 = 45$ sq.ft., which gives a velocity when passing 15,000 cu.ft. of air and gas, $15{,}000 \div 45 = 333$ ft. per min., before any air is added. Since the original current is half air and half gas, there are 7500 cu.ft. of gas and the same quantity of air in the original current. After one-half more air is added, the volume of air will be $7500 + 3750 = 11{,}250$ cu.ft. The total volume of the current of air and gas is then $7500 + 11{,}250 = 18{,}750$ cu.ft. The velocity is $18{,}750 \div 45 = 416+$ ft. per min.

The percentage of gas in this current is $7500 \times 100 \div 18{,}750 = 40$ per cent. If a lighted safety lamp was introduced into this mixture it would be promptly extinguished by the gas.

COAL AND COKE NEWS

Harrisburg, Penn.

Arrangements to get greater service out of cars and railroad facilities in the handling of coal were made at a recent conference of Lehigh Valley R. R. and Lehigh Valley Coal Sales Co. officers in Hazleton. Shipments in solid trains are to be made up so as to avoid shifting.

The daily output of domestic sizes of coal from the Prospect colliery is to be sent to the Lehigh docks at Jersey City for transshipment to New England. If the output of this colliery is not sufficient for the purpose, that of the Dorrance colliery, or part of it, will be added to the Prospect shipment.

The Hazleton region is to furnish coal for the west to be taken from Drifton and Hazleton No. 1 collieries and the Hazleton shaft. Shipments are to be made four days each week. Egg, stove, chestnut and other sizes of anthracite going west are to be sent to Jersey City, Newark, and other points for distribution. This will greatly aid New York.

The action was decided upon following the notice sent out by the Director General of Railroads that solid trains should go from collieries to tidewater points in order to avoid the unnecessary shifting of cars by the railroads.

Holding that a man whose hands are frostbitten in the course of his employment is entitled to compensation, an interesting and important decision in the courts on May 10 sustains the decision of the referee allowing compensation. The decision promises to become a leading one in all states having compensation laws, also in Great Britain, as several English decisions are quoted and a difference pointed out to distinguish the phrase "in the course of his employment," as contained in the Pennsylvania law, and "arising out of the employment," as contained in the English law.

In appealing from the decision the defendant company had complained that frostbite was not compensable under the act of 1915, because the injury (1) was not received "in course of employment," and (2) was not "violence to the physical structure of the body."

Judge Fuller admits that both propositions are exceedingly close and that he found difficulty in reaching his conclusions. He proceeds, however, in a convincing manner to decide both in favor of the claimant and quotes American and British decisions to show that consideration of employer's lack of control of the weather and employee's lack of precaution were only pertinent on the question of negligence or contributory negligence, which the Compensation Act entirely eliminates.

Fairmont, W. Va.

A. W. Calloway, Director General of Bituminous Distribution of the Federal Fuel Administration, made some important statements at last week's meeting of the Fairmont Coal Club. Too large a percentage of the coal is not needed in the war program, was one of his declarations, which was followed by an intimation that if the present policy of the Fuel Administration did not solve the problems which confronted the Government there was likely to be some sort of a different arrangement "before Christmas."

Mr. Calloway mentioned a growing insistence on the part of those controlling the war industries for what the Government classified as "No. 1" coal, and his remarks indicated that it was possible that coals which were most essential in war work would be given priority. One of the many trite statements with which he dismissed subjects which had given the local coal association much worry was that "priority assignment of coal was more important than the priority assignment of cars" in the "war program," to which reference was made on frequent occasions, which emphasized the fact that the war program took precedence in the workings of the Fuel Administration.

Mr. Calloway referred to the fixing of the price of railroad fuel and the doing away with the assigned car policy by a mere statement, not emphasized in any way, that the Fuel Administration and the Railroad Administration were dangerously near a break six weeks ago. The decision reached will benefit the war program, he insisted, and will not hurt the individual operator. He stated that the Fuel Administration knew what it was about when it insisted that the matter of railroad fuel contributed more largely to the war program than any other problem which had arisen, and made the point that every coal man was a part of the Fuel Administration and therefore interested in its problems.

Mr. Calloway said that it was unreasonable to permit the railroads to choose the best coal when other coal was almost as well suited for their purpose and the coal that was their choice was essential to the work of war industries.

If an equal distribution of cars did not solve the coal problem he thought readjustment necessary, and believed that mines producing "No. 1" coal, imperative in the demands of the war industries board, would be called upon to provide such coal under modified arrangements.

The idea advanced that the coal operators are a part of the Fuel Administration was new here. He supported the declaration by pointing out that the operators selected their own District Representative. Every operator had a right to protest, he said, in event that the District Representative erred, but in the event of no protest it was presumed things were working all right. He insisted that the inspection system was also in the hands of the coal operators. He took a more drastic attitude in this connection and said that if any man sent out coal not fit to be shipped with transportation conditions as they are at present, he does not deserve to be classed with coal men as now known and that such men ought to be "wiped off the earth" if necessary.

Charleston, W. Va.

Reports from all the coal fields in this section reached by the Chesapeake & Ohio disclose the fact that the car supply continues to improve, the supply averaging from 60 to 75 per cent. of total requirements or cars asked for, running as high as 75 per cent. in Raleigh County, where there are a very large number of operations. The same is true as to the New River District, where the percentage, however, is not quite so high.

Operators in the southern section realize that it will be necessary to materially increase the present output in order not only to meet the demands of war but to show a production greater than the last few years. The efforts of the coal mine owners to speed up production will depend upon two factors—cars furnished and the ability to secure labor. Questions have elicited the fact that miners are not putting in full time in the mines but are working only a fraction of the week and for only a sufficient period each week to meet their living expenses. Unless miners are awakened to the necesity of producing a greater tonnage, it will be impossible, operators contend, to reach the average and to forge ahead of previous marks. The loss in tonnage earlier in the year was very heavy owing to an inadequate car supply, and the tonnage shortage lost in that way must be overcome before the producer can hope to increase the output so as to make such production felt throughout the country.

While here and there in this section opposition to the zoning system is manifested, most of the operators and particularly those whose mines are in a field producing coal of a quality which always finds a ready market are reconciled to the zoning system, so long as it saves transportation and permits the steady movement of cars back and forth. This is particularly true as to the New River and Pocahontas districts.

For the most part the car supply in the Fairmont field was good last week, the region receiving 1458 cars on Monday, or nearly a full quota. On Tuesday the supply was somewhat less. However, the supply was sufficient throughout most of the week to create some enthusiasm and sustained hope of better conditions in the future.

Companies in this section are planning to make a record for coal loading during the week of June 3, which according to published statements is to be known as "Coal Week."

The first step in a move to extend the coal trade of West Virginia so that this state might compete with the Hun after the close of the war was taken last Wednesday, when coal men representing the various coal operators' associations of the state met in conference with Governor Cornwell at his office here to discuss plans for obtaining a wider market for West Virginia coal. Governor Cornwell opened the conference with a short address in which he alluded to German business methods and the necessity of introducing more efficiency into American methods if the American is to compete successfully with the Hun producer at the close of the war. He spoke of the possibilities which lie in the South American trade and dwelt particularly upon the necessity of introducing American coal and especially West Virginia coal into this trade. Once introduced, he said, America would be able to hold the trade because of the superior quality of American coal.

Birmingham, Ala.

A new stripping coal mine will be added to the list of Birmingham mines within the next 15 days, it is officially announced. This mine is located in the Blue Creek region in the southern part of Jefferson County. J. C. Maben, president of the Davis Creek Coal Co., is directing the new project. Machinery, including steam shovels, is now being placed and coal about 12 ft. thick will be worked.

Modernizing of present blast furnaces, in time, building of new furnaces, construction of a byproduct plant and other developments are said to be included in ultimate plans of the Sloss-Sheffield Steel and Iron Co., discussed last week by President J. W. McQueen with the chairman of the Board of Directors, Waddill Catchings, in New York.

While great trouble is being experienced in getting material, which may serve to retard to a slight degree the work contemplated, the plans are to be carried out in relatively short time, it is reported. The contemplated improvements, it is estimated, will represent an outlay of several millions of dollars.

The coal-mining district at the close of the present week has a larger number of men at work than ever before, but the percentage of increase in production is rather disappointing. Investigations, however, fail to determine whether this condition is due to a "laying-off" on the part of the miners during the week or because of a deficiency in the labor.

The tonnage is increasing, but none too rapidly, for there are demands coming in from all sides which are not being met promptly. Accumulation of coal for next fall and winter, as suggested by the Fuel Administrator, has not yet started in, and there is doubt expressed among the producers whether there can be a great amount of coal put into bins or other places for use next year.

Miners and employees at mines begin this week at the new wage scale, advances in tonnage and day scales having been granted all along the line. The miners get 5c. additional for mining, while the day labor will receive a greater per cent. increase.

PENNSYLVANIA

Anthracite

Georgetown—By spreading the burning culm over a flat surface and covering it with sand and clay, the Lehigh and Wilkes-Barre Coal Co. has started to extinguish a fire which has raged for months on a large culm bank between the Blackmand and Stanton collieries.

Plains—Fear of extended caving of the mining property of the White Coal Co. at Pittston has caused the operation to remain in idleness since early last week, when 20 homes were damaged by a settling of the surface. James C. White, president of the company, is awaiting a decision from the State Mine Inspectors. John Conlon, president of the Conlon Coal Co., will pay for the rebuilding of Sacred Heart Church there after its damage by a cave-in work-

ings he controls. Mr. Conlon showed a generous spirit, as it virtually has been proved the cave was caused by mining conducted 20 years before he bought the coal tract. Residents of this town have refused the offer of the Madeira Coal Co. to repair 40 homes that were shaken and torn by settlings of the earth due to robbing of the coal pillars. They are in hopes of finding a law that will give them more than mere property damages.

Dickson City—Work started on May 1 by the Delaware, Lackawanna & Western R. R., Coal Department, in the excavation of ground a few feet west of the present Storr's breaker, for the erection of a new breaker. The breaker will not be an all concrete structure such as the one owned by the Lackawanna company at Taylor. However, when finished, it will contain the latest in breaker-building and will be one of the largest and best equipped in the anthracite region. It will be erected practically along the same lines as the wonderfully equipped Loomis breaker at Nanticoke, only the construction will be on a larger scale. Its capacity will be 4000 tons of coal per day.

Harrisburg—Approximately 2500 tons of river coal are taken from the Susquehanna River daily. There are 27 pumps working daily above the dam and about a score below. At least 50 tons can be drawn from the river bed daily by one pump. One of the largest fleets on the river is that of the Harrisburg Light and Power Co., including seven pumps, four steamers and fifty flats. Another operator has the contract to supply the state capitol building with its yearly supply.

Bituminous

Dubois—The large A. C. Hopkins coal holdings to the northwest of this city are about to be opened by the Hopkins Coal Co., some of the workings to be within city limits and beneath land already built over. The output will be hauled by way of the Harriger mine to the Hildrup tipple, or to a tipple to be built nearby, a two-mile tramroad being constructed up Slab run.

Indiana—The Two Lick Coal Co. has started the sinking of two shafts on the Ajax property, about 1½ miles from here. The new mines will be electrically equipped and will supply most of the commercial and local trade for Indiana. F. L. Neff is general manager of the new operations.

Punxsutawney—The Onondaga shaft just north of Punxsutawney and operated by the Buffalo & Susquehanna Coal and Coke Co. for some time, but abandoned by this company about ten years ago, has been leased to several capitalists of Buffalo, N. Y. They have begun to install new machinery, build houses, repair the tipple, power house, etc. The mine will be electrically equipped, and it is planned to start off with a production of about 600 tons per day. This will be increased until the production is 2000 tons per day, the requirements of the manufacturers who have charge of the property.

Savan—The Dormar Coal Co. of Indiana, has started work on the drifts, tramroad, incline plane, etc., on the tract of land known as the Hamilton farm. The tipple will be erected on the present siding, known as Leisure siding, on the Buffalo, Rochester & Pittsburgh Railroad.

West Lebanon—The stripping plant of the Corbett Coal Co. has begun to ship coal. The stripping of the overburden has been going on for the past year, and at the present time several acres of coal are ready to be loaded. The first day's shipments totaled 1000 tons. The shipments are made over the Buffalo, Rochester & Pittsburgh Ry., and the railroad cars are handled from the switch at the main tract to the operation over a switchback railroad by the company's private locomotive.

WEST VIRGINIA

Clarksburg—The Franklin Gas Coal Co. has begun shipping coal from its mine at Interstate, having recently opened a mine at that point.

Four different coal companies with as many openings are mining coal from a tract of only 12 acres, near Mt. Clare, in this county. The coal is hauled to the siding at Mt. Clare and shipped in box cars.

Former Sheriff Ross Stout is developing a 40-acre tract of coal near Mt. Clare, shipping about three cars a day.

Wayne—Having acquired 700 acres of coal land in Wayne County containing three excellent seams of coal, the Tri-Vein Coal Co. is opening a mine. As soon as a siding is completed it will begin the shipment of coal.

Fairmont—A ten million dollar byproduct plant is to be established here and the Fairmont Byproduct Corporation has been granted a charter for the purpose. The incorporators are O. F. Lough, C. E. Smith, E. B. Moore, F. B. Pryor and W. J. Wiegel, who represent the Monongahela Valley Traction Co. and the Greater Fairmont Investment Co., two important local interests of which Senator C. W. Watson is the dominant financial interest. Fairmont district coal will be turned into coke under this plan at Fairmont, which will materially relieve the railroad congestion. The plan contemplates the erection of 110 ovens at a cost of $50,000 each.

Fairmont—A new record was established at the Federal mine of the New England Fuel and Transportation Co. when in one day it hoisted 1206 mine wagons, representing 3800 tons of coal, or a tonnage sufficient to load 76 railroad cars.

Fayetteville—The Mill Creek Colliery Co.'s power house, which was washed out during the flood of March 13, is being rebuilt. New equipment has been ordered and a part of it is now on the ground.

ILLINOIS

Carlinville—Miners employed in sinking the three new mines of the Standard Oil Co. north of here are agitating the formation of a new local, in preference to joining the locals at Carlinville or Nilwood. They sent Michael Kelly, engineer at one of the mines, to see President Frank Farrington at Springfield about it. Farrington notified the State Board, which will make an investigation and probably grant the men at the new mines a charter, which will be the 301st in the state. It is expected that about 2700 men will be employed at the three mines.

O'Fallon—Work at Nigger Hollow mine No. 2 was halted one day this week while about 300 miners disciplined John Kupala, one of their number, for alleged disloyalty. Kupala has been earning $150 and $175 a month, but when asked to buy a Liberty Bond said that he had bought one. Some of the miners investigated and found that he had not. He was confronted and is alleged to have said something disloyal. He was permitted to go down, but later he was seized and taken to the top and tar and feathers were prepared. He fell on his knees and begged for mercy. A flag was brought and he kissed it. He was then permitted to leave.

Belleville—Fire believed to have been of incendiary origin recently destroyed the tipple and shaker house of the Little Oak mine, causing a loss estimated at $12,000 to $15,000. The fire started in the tipple and spread to the shaker house. There were large quantities of coal in both structures. The miners had departed 45 min. before the fire was discovered. The mine is owned by the Southern Coal, Coke and Mining Co. The 275 employees are thrown out of work. The mine was listed as 100 per cent. on third Liberty Bonds, but some of the miners bought with such manifest reluctance that they were threatened with a ducking. The State Fire Marshall has been asked to make an investigation.

Foreign News

Zurich—According to advices received from Vienna, the Austrian Minister of Railways recently announced the entire suspension of passenger traffic on the northern railways. This action was taken because of a shortage of coal, due to a strike of miners.

Brockville, Ont.—The St. Lawrence Coal and Freighting Co., Inc., was organized May 3 by the election of officers as follows: President, E. F. McCourt, Montreal; vice president, E. J. Burns, Ogdensburg; treasurer and managing director, J. A. Bresnahan, Brockville. The company will undertake to meet coal and freighting requirements at lake and river ports from Belleville to Cornwall, supplying a want which has for the past few years been a serious drawback to the coal trade.

Sydney, N. S.—Officials of the Dominion Coal Co. state that owing to the continued lack of shipping facilities it is quite improbable that much coal will be sent from Sydney up the St. Lawrence this season. The company finds it difficult to secure adequate vessel accommodation for the Maritime Province trade, and if coal is needed in any large quantities in Quebec or Montreal, purchasers will have to send their own ships to Sydney for cargo. This was done to some extent last year. Steamers will probably be sent by the Canadian Government Railways to bring coal to Levis, Que., to be distributed from that point.

Obituary

Carvin Pardee, Jr., general manager of Pardee Brothers & Co., Hazleton, Penn., widely known anthracite coal operators, died on May 13 from appendicitis.

Leo Miorelli, of Hazleton, Penn., 35 years old, national organizer of the United Mine Workers and member of the executive board of District No. 7, died after a long illness, on May 2. He worked for the miners' union in almost every state in the East and South.

Personals

C. E. Bockus, of Dante, Va., president of the Clinchfield Coal Corporation, has been elected a director of the National Coal Association, of Washington, D. C.

John Osborne, of Ashley, Penn., has been appointed outside foreman of the Maxwell No. 20 colliery of the Lehigh and Wilkes-Barre Coal Co., to fill the vacancy caused by the death of D. C. Tiffany.

Andrew K. Morris, superintendent of docks for the Erie Railroad Co., has been appointed director of tidewater coal traffic by the Anthracite Committee of the Fuel Administration and will have his offices at No. 50 Church St., New York City.

D. B. Wentz, of Philadelphia, Penn., president of the Stonega Coal and Coke Co., has been commissioned a lieutenant-colonel in the Quartermaster Corps of the Army. Colonel Wentz probably will be sent to France in the very near future.

Thomas Gambold, of Wilkes-Barre, Penn., who has been employed for a number of years as inside superintendent at the Stanton No. 7 colliery of the Lehigh and Wilkes-Barre Coal Co., has been promoted to the same position at Maxwell No. 20 colliery.

Charles O'Neill, formerly connected with the United Mine Workers of the central Pennsylvania District, and also the Fuel Administration, Washington, D. C., has been elected secretary of the Central Pennsylvania Coal Producers' Association, Altoona, Penn., recently formed.

C. F. Taylor, who was a member of the engineering firm of Harrop, Hopkins & Taylor, of Pittsburgh, Penn., has retired to take charge of the coal stripping operations of the Kehota Mining Co., of Zanesville, Ohio. H. S. Harrop and N. F. Hopkins will continue the engineering business as Harrop & Hopkins.

Charles Philip Coleman, who has been vice president of the Worthington Pump and Machinery Corporation, of New York, since May, 1916, was recently elected to the presidency of the company. The corporation, aside from pumping machinery, manufactures mining machinery, air compressors, gas power engines and blowers, crushing and cement equipment and water works engines.

D. C. Botting, of Seattle, Wash., former state mine inspector and now secretary of the Coal Producers' Association and Commissioner for the Washington Coal Operators' Association, has been appointed district representative of the Federal Fuel Administration. Until the Federal Government assumed control of fuel Mr. Botting devoted most of his time to working problems that arose between the operators and their men. He was largely instrumental in negotiating for the wage increases that were granted miners in the State of Washington last year and in effecting the latest agreement, which became effective last November, by which the miners and operators fixed a wage scale which is to be binding for the duration of the war. One of his principal duties in his new work will be to speed up production of coal in the state.

Trade Catalogs

Blasting Caps and Electric Blasting Caps. Aetna Explosives Co., Inc., New York. Booklet. Pp. 12; 3½x6 in.; illustrated. This little booklet contains in concrete form valuable information and data relative to the use of blasting caps. Precautions for the handling and storing of caps are given.

The Milburn Light. Alexander Milburn Co., Baltimore, Md. Catalog. Pp. 48; 6 x 9 in.; illustrated. An unusual feature of this well printed catalog is the embodying in the catalog itself of the complete directions for using the Milburn portable carbide lights. Several oxyacetylene torches and generating plants are also described.

Lower Pumping Costs with E-M Synchronous Motors—Electric Machinery Co., Minneapolis, Minn. Bulletin 183. Illustrated. 24 pp., 8½ x 11 in. The purpose of the bulletin is to demonstrate what the synchronous motor is now doing in the pumping field. Though not pretending to be an exhaustive analysis of the subject, anyone can gain from this bulletin an accurate idea as to the present status of centrifugal pump design and the duty required of the driving motors.

Coming Meetings

American Concrete Institute will hold its annual meeting June 24-26, at Atlantic City, N. J.

American Institute of Chemical Engineers will hold its summer meeting June 19-22 at Berlin, N. H.

Illinois Mining Institute will hold its next meeting May 23, 24 and 25, at Peoria, Ill. Secretary, Martin Bolt, Springfield, Ill.

Illinois and Wisconsin Retail Coal Dealers Association will hold its annual convention June 26 and 27, at Hotel Wisconsin, Milwaukee, Wis.

National Coal Jobbers Association will hold its annual convention at Buffalo, N. Y., June 4. Secretary, L. Romanski, Old Colony Building, Chicago, Ill.

American Institute of Electrical Engineers' annual convention June 26-28 at Atlantic City, N. J. Secretary, F. L. Hutchinson, 29 W. 39th St., New York City.

American Society of Mechanical Engineers will hold its spring meeting June 4-7 at Worcester, Mass. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

National Coal Association will hold a meeting May 28 and 29 at the Bellevue-Stratford, Philadelphia, Penn. Secretary, J. D. A. Morrow, 707 Southern Building, Washington, D. C.

Illinois and Wisconsin Retail Coal Dealers Association will hold its annual convention June 26 and 27, at Milwaukee, Wis., with headquarters at Hotel Wisconsin. Secretary, Isaac L. Runyon, Chicago, Ill.

National Retail Coal Merchants Association will hold its first meeting at Hotel Traymore, Atlantic City, N. J., Monday and Tuesday, May 20 and 21. Corresponding secretary, Jesse C. Suter, 1727 Pennsylvania Ave., N. W., Washington, D. C.

International Railway Fuel Association will hold a convention May 23 and 24, in Chicago, Ill., under the auspices of the United States Fuel Administration, and the United States Railway Administration. Secretary, J. G. Crawford, 702 E. 51st St., Chicago, Ill.

Industrial News

Charleston, W. Va.—The Dunlow Coal Co., of Williamson, Harry Scheer, president, has given notice of its intention to surrender its charter and discontinue business.

Philadelphia, Penn.—The Electric Service Supplies Co. annnounces that it has secured larger quarters for its New York office in the Hudson Terminal Building, 50 Church St., now occupying rooms 1771 and 1773.

Birmingham, Ala.—J. C. Maben, Jr., former vice president of the Sloss-Sheffield Steel and Iron Co., has announced that he will develop an extensive stripping operation in the Blue Creek field. Equipment is now being procured and placed.

Jersey City, N. J.—The Central Railroad of New Jersey, Communipaw Avenue, has contracted with the Robins Conveying Belt Co., 13 Park Row, New York, for the installation of a new belt conveying system at its coal pier No. 18, Jersey City.

Hazard, Ky.—The Industrial Engineering Corporation is the name of a new company that has been formed by R. L. Cornell, former general manager of the Kentucky River Power Co., to do all classes of electrical and mechanical consulting work and installation for the mining interests of this state.

New Lexington, Ohio—The Star Manufacturing Co., manufacturer of mine cars and mine-car equipment, is making a large addition to its plant, which will be ready for occupancy within 60 days. With its added facilities the Star company will be enabled to turn out 50 completed mine cars every day.

Wilmington, N. C.—The Cement Products Co., of Wilmington, N. C., manufacturer of the "Sanisep" portable sewerage disposal systems, announces the completion of its new electrically operated factory plant. This expansion of the manufacturing capacity is made necessary by the increased use of the "Sanisep" tanks in the coal towns as well as other industrial villages.

Altoona, Penn.—Substantial progress in furthering the organization of the new Central Pennsylvania Coal Producers' Association, which was launched at a meeting held in this city on April 24, was made at a meeting of the executive committee held here May 9, when Charles O'Neill was employed as general secretary and W. A. Jones as statistician, and John Lloyd, Jr., was elected permanent treasurer.

Russell, Ky.—Figures compiled here at the coal pool offices show that all records for movement of coal north have been broken since this coal pooling office was opened. The daily average number of loaded coal cars passing over the Chesapeake & Ohio during the first part of May was 1391 cars. The coal from the mines is shipped to Russell, from which point it is distributed in train loads, under the new Federal regulations.

Hazard, Ky.—The Electrical Supply and Repair Co. will begin at once the construction and installation of a large electrical repair shop and machine shop at this place. The concern, which is a new one, will also carry a large stock of electrical and mine supplies and equipments. L. B. Turnbull is president, and associated with him are R. L. Cornell and E. C. Carlin. It is understood that several well-known coal operators are financially interested in the new enterprise.

Fairmont, W. Va.—At a special meeting of the Central West Virginia Coal Operators' Association C. H. Jenkins, president of the district organization, was elected member of the executive committee for the West Virginia Coal Association, the state organization, the executive committee of which will organize at the Frederick Hotel at Huntington, June 1. At the same meeting J. H. Wheelwright and J. J. Tierney were named as directors of the National Coal Association.

Newport News, Va.—The Chesapeake & Ohio Railway Co., Richmond, is planning for the construction of a large new coal-storage plant at its local properties to have a storage capacity of 200,000 tons. The company has arranged for an extension to its trestle and trackage system to provide for an ultimate increase to 300,000 tons. Machinery for daily loading out to have a capacity for 6000 tons will be installed, this output to be ultimately increased to 12,000 tons.

Columbus, Ohio—Reports of loading at the Toledo docks during the week ending May 10 showed a large increase over the previous week. The Hocking Valley docks loaded 118,248 tons as compared with 85,810 tons the previous week. The total handled since the opening of the season is 250,150 tons. The Toledo & Ohio Central docks handled 47,000 tons as compared with 38,000 tons the previous week, making a total of 134,000 tons since the opening of the season.

Pittsburgh, Penn.—The E. J. Frauenheim Coal Co. calls attention to the fact that the item printed in the issue of May 11 relative to its operations reads as if the company was a recent organization about to start its development work. The E. J. Frauenheim Coal Co. has been organized for about one year, having already completed its two miles of railroad track. It is at the present time electrically equipped, the equipment being installed to handle 1000 tons of coal per day eventually.

Columbus, Ohio—An order has been issued at Washington changing the control of the Bureau of Coal Statistics, which has been operated in Columbus by all coal carrying railroads for more than 30 years. W. D. McKinney, a personal representative of the Federal Fuel Administration in southern Ohio, will be in charge. F. V. Davis, the present superintendent, will continue in that capacity. The bureau is regarded as one of the most valuable statistical collecting agencies in the Middle West, and a fight was required to keep it in operation.

Louisville, Ky.—Much interest has been shown by coal operators in the efforts of the Government to more evenly distribute labor through the opening of six Federal Labor Exchange Bureaus in Kentucky. One of these will be located at Fifth and Market Streets, Louisville; and others at Paducah, Henderson, Newport, Covington and Ashland. None of these offices are in the real coal districts, but several are not so very far removed. It is claimed that these bureaus will endeavor to prevent excesses in one place and shortages in others, and will work with the established bureaus and bureaus in other states.

Jefferson City, Mo.—The Missouri State Retail Coal Merchants' Association, at its first annual meeting here, indorsed the plan to pool all anthracite coal shipped into the state and have it distributed by the Missouri fuel administration. The opinion of the convention was that such pooling would result in each section of the state receiving its pro-rata supply, based on the business of 1916 and 1917. The following officers were elected: I. C. Knotts, St. Joseph, president; T. E. Williams, Springfield, vice president; E. J. Wallace, St. Louis, secretary and treasurer. Knotts and Wallace were elected delegates to the National Association, which will have its annual meeting May 21 at Atlantic City. Missouri Fuel Administrator Crossley and several prominent coal men delivered addresses.

Cincinnati, Ohio—The United States District Court has entered an order approving the contract entered into by John S. Jones, of Chicago, with the Hocking Valley Railway Co., for the purchase of $2,606,000 of bonds of the Sunday Creek Coal Co. at 25c. on the dollar, or about $626,531, thereby virtually holding that Jones now has valid title to the coal lands formerly owned by the Sunday Creek Co. in the Hocking Valley, about 25,000 acres. This is true because of the fact that the remainder of the company's $14,000,000 of outstanding bonds, held by several railroad companies, have been liquidated by the transfer of other properties covered by them. The Jones purchase was made as the result of an order of the court in 1914, requiring the railroad companies to dispose of all of their interests in the coal companies operating in the Kanawha and Hocking Valley fields. It is understood that large operations in the old Sunday Creek properties will now be pushed by Mr. Jones.

St. Louis, Mo.—Joseph W. Folk, general counsel of the Chamber of Commerce, has written to Attorney-General Gregory at Washington requesting that the Government institute contempt proceedings against the Terminal Railroad Association for violation of the United States District Court in enjoining the association from acting as an independent road between the east and west banks of the Mississippi River, and from making an arbitrary charge on traffic originating within the 100-mile zone that is not applied equally on traffic originating outside of the zone. The request is based on admissions in the answer of the Terminal association to the petition of the Chamber of Commerce to the Interstate Commerce Commission for the abolition of the arbitrary. These admissions are alleged to be that the Terminal association is an independent corporation and that the arbitrary of 20c. a ton on coal is imposed on shipments originating within the 100-mile zone and not on shipments originating outside of that zone.

Dallas, Tex.—C. W. Dawley, who owns much of the stock of the McAlester Coal Fields Co., of McAlester, Okla., is promoting a railroad to run from a point on the Rock Island near McAlester southeastward through a new coal field that is now being opened, and which promises to develop into one of the richest coal-mining sections of the state. The new railroad will leave the Rock Island between Dow and Bache, and will make use of what is now known as the Rock Island High Hill spur. The line will be of standard gage and its terminus will be about 3½ miles south of McAlester. Steel ties and other materials for its construction are now on hand and grading is going forward with all possible speed. Work of clearing away the overlying earth from the coal veins in the new field which will be tapped is now going forward, and it is desired to have the line completed and in operation before the winter sets in, as it is purposed to mine considerable coal and have it in storage for the early winter. Stripping operations will be carried on extensively in the new field, as the coal veins lie near the surface and the coal can be profitably mined with steam shovel.

Weekly Review

Drive To Be Made for Coal Orders—Production Sufficient for Immediate Needs Only—Anthracite Restricted to Eastern Seaboard—Car Supply Still Factor in Bituminous Production—To Conserve Fuel in Power Plants—Lake Trade More Active

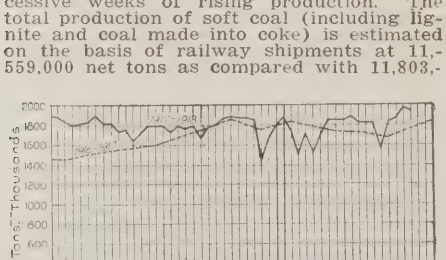
WE HAVE had Liberty Bond drives, Red Cross drives—and now there will be a drive for coal orders. During "Coal Week"—June 3 to 8—the Fuel Administration will redouble its already strenuous efforts to induce consumers to order their coal early. Thus the mines will be enabled to make immediate deliveries of all the coal that can be mined during the summer and to that extent help relieve transportation conditions next winter.

In the meantime coal production is barely keeping pace with the demand for fuel needed for immediate consumption. Some few plants here and there are accumulating reserve stocks, but a lack of sufficient storage space will prevent many from laying in much larger supplies.

Anthracite production is now at its maximum. The April shipments amounted to 6,368,372 tons, an increase of 776,074 tons over the corresponding month of 1917. Increased demands have absorbed the entire output, and no reserve stocks of any consequence remain in the hands of dealers. By order of the Director General of Railroads, shipments from the anthracite collieries to tidewater points are hereafter to be made up in solid trains, thereby doing away with the loss of time entailed by the unnecessary shifting of cars by the railroads. To further restrict the consumption of hard coal to those sections of the country where it is more urgently needed, no anthracite will be permitted to move west of the Mississippi River or into the South. The lifting of embargoes affecting New England, however, has resulted in the larger movement of much-needed coal to that quarter.

The steady increase in the production of bituminous coal recorded for three successive weeks suffered a setback during the week ending May 4, when 11,559,000 net tons were shipped. Telegraphic advices show that production for the week ending May 11 practically equals that of the week ending May 4. The greatest factor limiting production is the old one of inadequate car supply. Labor trouble in one Pennsylvania district further serves to diminish output, while in Alabama, where the car situation is fairly good, the miners refuse to work full time through inherent laziness more than anything else.

We still have with us the controversy regarding the price of railroad fuel. Owing to the illness of Mr. McAdoo this question remains unsettled. The railroads are buying coal on a hand-to-mouth basis and refuse to enter into contracts. The operator is thereby prevented from making contracts with other consumers, as the moment the situation clears the railroads will have the first call on the output of the mines. It can readily be seen that in the situation as it now exists there is no stimulus to production.



The necessity of keeping American industry going at high speed with the supply of coal that will be available this year has led to the inauguration by the Fuel Administration of a fuel-conservation movement in industrial power plants.

By the correction of firing and operating methods in industrial plants Dr. Garfield hopes to save at least 25,000,000 tons of coal. Each power plant is to be inspected by engineers appointed by the Fuel Administration. While no mention has been made to this effect, it is probable that plants with the lowest ratings will be the first to be cut off when there is not enough coal to go around.

The lake trade is becoming more active, as the ice is moving out of the upper lake passages rapidly. The vessel movement is better and considerable coal is now going to the Northwest. Coal-loading docks on Lake Erie are dumping an average of about 700,000 tons a week into lake freighters. The quantity loaded should amount to about 1,000,000 tons a week if the plans to supply the Northwest before next winter are to be realized.

COAL PRODUCTION

Bituminous output declined slightly during the week ended May 4, after three successive weeks of rising production. The total production of soft coal (including lignite and coal made into coke) is estimated on the basis of railway shipments at 11,559,000 net tons as compared with 11,803,000 net tons during the preceding week, or a decrease of 2 per cent. Production per working day is estimated at 1,927,000 net tons, considerably in excess of 1,829,000 net tons, the average during May, 1917. Production of beehive coke is estimated at 657,000 net tons, an average of 110,000 net tons per working day, as compared with 123,000 net tons during the preceding week. The decrease in production during the past week amounted to 11 per cent.

Byproduct Coke—The high standard of performance reported from byproduct operators last week was equalled and even exceeded during the week ended May 4. The ratio of production to maximum capacity rose from 89.1 per cent. the preceding week, to 89.6 per cent. Out of the 10.4 per cent. of maximum capacity which the operators of the country failed to realize in actual production, 3.7 per cent. was lost through lack of coal; 0.6 per cent. on account of labor trouble; 4.5 per cent. through repairs to plant; 0.3 per cent. because of "no market," and 1.3 per cent. for all other causes.

Operating conditions in the various states varied but little from the performance of the week before. Indiana reported the only material increase, the ratio of production to maximum capacity rising from 79.2 per cent. the week of Apr. 27 to 85.6 per cent. Increased supply of byproduct coal was the direct cause of the improvement. Kentucky was the only state to record a material decrease, the producing ratio declining from 90.3 per cent. the preceding week to 85.8 per cent. Repairs to plant was the cause given as limiting production. Pennsylvania, the largest producing state, is reporting the least favorable conditions and is now operating at 82 per cent. of capacity.

Beehive Coke—Shortage of yard labor limited production of beehive coke in the Connellsville and adjacent regions during the week ended May 4, causing a loss of potential capacity of 18.2 per cent. as compared with losses due to shortage of yard labor during the week ended Apr. 27 of 11.5 per cent. Sixty-three of the principal operators in the Connellsville, Greensburg and Latrobe Districts of Pennsylvania produced 324,100 net tons of coke, or 70.4 per cent. of their maximum capacity. Losses due to transportation conditions declined from 8.6 per cent. the week of Apr. 27 to 6.3 per cent. Mine disability was given as causing a loss of 3.6 per cent. The same operators produced 150,550 net tons of coal.

CARLOADS OF COAL AND COKE ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended Apr. 13	Apr. 20	Apr. 27	May 4
Bituminous shipments, 123 roads	188,311	193,667	204,527*	202,351†
Anthracite shipments, 9 roads	37,760	39,130	39,522*	40,570†

* Revised from last report. † Subject to revision.

Anthracite shipments during the week ended May 4 rose to 40,570 cars, the largest since the week of Mar. 30.

BUSINESS OPINIONS

Bradstreet's—Improvement in weather conditions, crops, trade, especially at retail; industrial outputs, general rail and water transportation, and last, but not least, in stock market sentiment and dealings, constitute a sextet of favorable features in the week's reports. With the Third Liberty Loan largely overscribed, the business world seems to have turned its attention back to trade and industry, this process being, no doubt, facilitated by better weather, more optimistic crop reports and insistent government demand for all sorts of materials.

American Wool and Cotton Reporter—There has been no great change in the woolen goods market during the week under review, and the situation is likely to continue much the same until the very pressing need for Government fabrics is more fully supplied. The question of greatest importance at the present is in regard to the supply of goods which will be available for civilian purposes. In the first place, the Government has taken all the wool available, and is naturally making provision for the consumption of whatever raw material seems necessary to supply the goods needed. Until the total amount required is more definitely known it will be impossible to determine what the quantity of civilian production may be, or even the general character of such production.

Dry Goods Economist—The shortage of supply of raw materials shows no sign of improvement. In consequence manufacturers of various textiles find themselves unable to continue production of goods on order, or to undertake to make up new goods. Cotton prices are receding slowly on the New York Cotton Exchange. The changes, however, only affect the short staple which is suitable for the production of various heavy fabrics. Therefore, there has been no reduction in the cost of finished fabrics for household use or for women's wear. Cotton fabrics, like those of wool, are much needed by the Government and therefore production for ordinary commercial uses is far below normal. Under these conditions no downward revision of prices can be looked for.

Atlantic Seaboard

BOSTON

Cancellation of "Storrow order" discloses large number of industries unable to secure coal in sufficient volume for current needs. Unless receipts improve there are likely to be shutdowns even this summer. Anxiety increases over outlook as it is realized that "priority" will probably be necessary in order to get coal this fall. Assigned cars still being placed for railroad fuel. Undue demands being made upon central Pennsylvania. Efforts to increase movement via Hampton Roads meet with obstacles. Coal still in excess of bottoms at Southern piers. Textiles placed on preferred list. Baltimore & Ohio deliveries still disappointing, and movement on foot to exclude coals on that road from New England all-rail. Anthracite rail shipments somewhat improved, but receipts by water are meager. Fuel authorities encourage use of buckwheat and other steam sizes.

Bituminous—The large number of industries that were practically dependent upon the regular movement of "Storrow coal" all-rail has been brought prominently forward since the Garfield order of Jan. 3 was cancelled ten days or so ago. It was emergency coal, destinations in some cases being changed from day to day to meet urgent cases, and the lack of this tonnage will soon be keenly felt. It not only supplemented shipments through the usual channels all-rail, but it also helped out many plants that ordinarily rely wholly upon water receipts, but this season could not have been kept in operation without help all-rail. The coal coming forward under this arrangement never amounted to as much as 300 cars daily, although the original authorization was usually referred to as the "500-car order." The average for about 100 days was slightly in excess of 100 cars, including those furnished to certain of the railroads under the same terms, and the order therefore was only about 20 per cent. effective. The 20 per cent., however, was of great assistance, especially during January, February and March, in keeping important activities in operation.

The New England situation is decidedly serious. Tidewater receipts from the Virginia terminals are meeting the requirements of the very largest industries that for the most part are within 40 miles of rehandling piers, but so far there has been no opportunity to stock up. The important plants usually served all-rail are hard put to it to keep a fortnight's supply ahead. Coal is sought from every possible angle and frequently a big mill will draw supplies from three or four different discharging ports, paying differentials regardless of cost, and seeking to "borrow" railroad fuel to help out slim receipts all-rail.

Another feature of the present situation is the undue demand that is being made upon the central Pennsylvania district. Labor conditions there are none too good, chiefly owing to the high wages paid, and it is doubtful if output could be much increased even if better car-supply were forthcoming. The shortage of boats for Hampton Roads loading and the excess of boats over coal at the New York piers, together with the large differential in price in favor of Pennsylvania coals, are factors in the heavy demand. A considerable number of low volatile coals in this district have been practically segregated for bunker fuel to be furnished at New York, and the requirements at that port on account of traffic being sent there for oversea transport is in much greater proportion than in normal times. Connecticut points reached via New Haven are also eager to get Pennsylvania low volatiles, and so great is the pressure that the Fuel Administration at Washington has intervened to say that large tonnages for that area should be furnished from Hampton Roads. The difficulty there, however, is transportation, and there seems no ready solution.

Notwithstanding rulings of the fuel authorities assigned cars are still being placed for engine fuel. Certain mines west of Altoona, Penn., were furnished no other equipment a week ago, and there are whole groups of mines where for weeks at a time there is no commercial coal available. Until railroad fuel is definitely adjusted and some working basis is devised there are bound to be inequalities in distribution.

At Hampton Roads there continues more coal on hand than there are steamers and barges to take it away. Shippers are casting longing looks in the direction of the Lakes, where 3000-ton steamers are beginning to start through the canals for coastwise service. A number of these boats are scheduled to load Dominion coal at Cape Breton for different New England ports in the effort not to waste transportation or to leave out any move that will secure coal for our industries. The latter are responding gladly, and it is certain that the 100,000 tons in view from this source will be readily absorbed.

Operations on the Baltimore & Ohio R.R. continue to be seriously hampered by poor car supply, although the past week there has been a slight improvement. A new difficulty faces consumers here who rely upon tonnage from that quarter, for this week there have been wholesale diversions to tidewater piers such as those at Curtis Bay and Port Covington of coal destined all-rail into New England. It has been customary for these coals to be confined rather rigidly to points on the New Haven road, but if from industries on this line this supply is to be thrown to tidewater on the assumption that boats will be forthcoming to move it a very serious mistake will be made. If the important plants of Connecticut are to be excluded from the Myersdale and Fairmont region as well as from central Pennsylvania they will be orphans in fact.

Anthracite—There is practically no change in the movement of anthracite, except for somewhat better volume all-rail now that the gateways are all open. Water shipments are still very low and sizes are not well assorted. Points along the Maine coast are being favored on account of the ruling of the distributing committee. It is an interesting fact that the first 10 days in May 31 per cent. of the total anthracite moving into New England was culm and steam sizes. The local fuel authorities are strongly encouraging the use of these coals to supplement bituminous in view of the shortage of bituminous that is certain to prevail next season.

NEW YORK

Anthracite market continues to be active with no let-up in demand. Dumpings at the local docks indicate larger shipments, but much of it goes to New England. Local retail dealers have plenty of orders to keep them busy for months to come. The bituminous situation serious, with bunker coals in good demand.

Anthracite—The situation continues to be active. Reports show comparatively little increase in receipts, while the coal goes direct from the dock to the consumer's cellar. As has been the case for some time, many yards are without coal, and this condition is not confined alone to the small dealer but involves some of the yards of the larger dealers as well. There is a persistent effort on the part of every consumer to get his winter fuel in his cellar, and he is being urged on by frequent statements from Fuel Administration officials, which in the opinion of some dealers are at this time unnecessary in the face of existing conditions. Local dealers are well supplied with orders, sufficient in most cases to keep them busy for some months, even though they received no more.

Conferences have been held during the past week between representatives of the Federal Fuel Administration, including Dr. Garfield, and the local forces regarding the situation, with particular reference to the desires of the city officials to store at least 300,000 tons of coal to be sold to the poor during the next winter. The chief obstacles in the eyes of those responsible for the carrying out of the plan, outside of securing the coal, is a place or places where the coal can be stored and then the work of distribution next winter.

Nearly a thousand cars more of anthracite were shipped to market during the week ended May 4, according to reports, than were shipped during the previous week, while the dumpings at the New York tidewater docks for the nine days ended May 13 were 8875 cars as compared with 7303 for the seven days ended May 4, an increase of 1572 cars. While these statistics indicate a large increase in dumpings, it must be remembered that considerable of this coal was for shipment by water to Eastern points, the amount of domestic sizes available for New York trade remaining only moderate.

The arrangement by which a part of the output of certain companies is to be sent direct to the local tidewater docks and nearby storage grounds ought to alleviate conditions.

The steam coal situation is easier. Buckwheat No. 1 continues in good demand, but rice and barley are such that some is being stored by large consumers.

The President of the Borough of Manhattan will open bids on May 20 for 7500 tons of buckwheat No. 1 and 36,000 tons of buckwheat No. 2, besides large tonnages of the other sizes.

The Board of Education will buy $65,000 worth of coal in the open market because of the nonreceipt of bids for furnishing the schools in Brooklyn, Queens and Richmond with fuel next winter.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual
Broken	$6.15	$6.90
Egg	6.05	6.80
Stove	6.30	7.05
Chestnut	6.40	7.15
Pea	4.90	5.65
Buck	4.45@5.15	4.80@5.50
Rice	3.90@4.10	3.80@4.50
Barley	3.40@3.65	3.00@4.00
Boiler	3.65@3.90	.....

Bituminous—There has been little if any improvement in the local situation. Demand continues heavy with no coal to meet it, and shippers are unable to meet the calls made upon them; consequently there is comparatively no coal being stored in anticipation of next winter's needs.

Production for the week ended May 4, according to reports, was not so heavy as during the previous week, a decrease of 2 per cent. being noted, while at the New York tidewater docks 7810 cars were dumped during the interval between May 4 and May 13 inclusive.

Conferences have been held during the week which were participated in by representatives of the Railroad and Fuel Administrations and the Shipping Board, looking toward improvements in the situation, with particular references to shipping.

The question of pooling the boats in the harbor is again attracting much attention and is looked upon favorably by most shippers. Much complaint is heard regarding the holding up of boats for several days at the docks, meantime the demurrage charges are piling up and taking away whatever profits there might have been in the sale of the coal.

There has been practically no change in the car situation, but operators and shippers are hopeful and with higher temperatures due look for much better conditions.

New England buyers continue to urge shipments.

Bunker fuel is in good demand and complaint has been heard of some slight delay in sailings, because of its shortage.

BITUMINOUS PRICES

	F.o.b. New York Gross	Mine Price Net	Gross
Central Pennsylvania	$5.06	$3.05	$3.41
Maryland:			
Mine-run	4.84	2.85	3.19
Prepared	5.06	3.05	3.41
Screenings	4.50	2.55	2.85

PHILADELPHIA

Anthracite shipments unsatisfactory. Some hope of early improvement. Retailers fear labor shortage. Some complaint of preparation. Buckwheat order ignored by some. Storing of steam coals. All sizes fully taken, with some easiness in rice. Bituminous shipments do not increase. Small tonnage equitably distributed. Labor unrest again.

Anthracite—With slow shipments and slower deliveries by the railroads, conditions cannot be said to have improved. There is little coal in the dealers' yards, but this would be the case even if shipments had been heavier. It is just possible the dealers are more optimistic than last month, as they are beginning to believe they will receive much heavier shipments during the summer months. In normal times there is practically no family business during July, August and early September. This year, if the shipments are as substantial as the dealers are led to believe they will be, they will undoubtedly make heavy inroads on the large volume of business now on their books. It will mean an unusual summer for both men and teams, and at this time we hear as much fear expressed over the scarcity of labor as of coal. Many dealers have quietly increased the wages of their delivery forces, yet many of the men continue to be weaned away by the fancy prices being paid at the immense war plants hereabouts for the most ordinary labor.

Shippers of coal have been advised of the general embargo on carload freight which became effective on the 15th. While it is too early to note definite results, it is felt that it will do much toward relieving congestion on the railroads and hasten coal deliveries.

While the dealers continue to read about the greatly improved preparation of the coal they are to receive, due to Federal supervision, it is a fact that considerable undersize coal is coming to this market. Possibly the most general complaint is the percentage of pea in the chestnut. Dealers who refrained from even calling the shippers' attention to inferior coal during the great scarcity of the past winter say that when they were doling out their coal in lots of one ton or even a less quantity this matter of preparation was not so important. Now, however, they state their trade are inclined to be critical and are objecting to having their cellars filled with poor coal.

The shipping companies have received a notice clarifying the situation as to shipments to Canada. The National Administration stated that while the permits which had been issued specified the quantity, this was only to be construed to mean the maximum tonnage that they will be permitted to ship under any circumstances, and is not to be considered as an order; but that the distribution is to be controlled by the Administration as it may see fit, by instructions issued from time to time.

In the steam trade all sizes continue to be quickly absorbed, and while all the tonnage is not going for immediate consumption, yet even this is much heavier than last year. We notice that big consumers of steam sizes are receiving quite a little tonnage in excess of their current requirements and are stocking the coal in various open spaces throughout the city. This applies particularly to concerns such as department stores, etc., who formerly had not been accustomed to laying in reserve stocks. If there is one steam size easier than any other it is rice, and a few cars of this size are often obtainable by a new consumer, especially from the larger companies, who are operating big washery operations at this time.

The prices per gross ton f.o.b. cars for line shipments and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.05	Buckwheat	$3.15	$3.75
Egg	4.50	5.70	Rice	2.65	3.65
Stove	4.75	6.05	Boiler	2.45	3.55
Nut	4.85	6.10	Barley	2.15	2.40
Pea	3.45	4.35			

Bituminous—There has been no increase in the tonnage of bituminous coal received in this city. Rail congestion and car shortage continue to hold back production and little, if any, improvement has been shown recently. Your correspondent interviewed a prominent shipper this week who gives it as his opinion that a great proportion of the congestion is caused by the consignment of the enormous quantity of general freight to New York harbor piers for loading. The claim is made that the pier and loading facilities of other ports are not utilized to their utmost, due to the fact that in ordinary times railroads have discriminated in favor of the above-named port.

While the coal supply in the city has continued short, yet we do not hear of the closing down of plants as was common a short time since. There is no doubt that this is due to the equitable manner in which such coal as does reach here is distributed by the committee of coal men who have been working with the fuel committee for some months past. They have now got the plan in such a shape that they are prepared to meet almost any emergency. Of course, no one is able to accumulate a surplus under this arrangement, but the committee is able to see that every plant is receiving a proportion of coal coming into this market.

With the strike in the Huntingdon and Broad Top region the question of wages among the miners is once more coming to the fore. The present difficulty was caused by the fact that up to April the operators in that region had voluntarily been paying the men a bonus of 10c. a ton. However, the Federal authorities have ruled out this provision as a discrimination and as a consequence the men are asking for increased pay. The movement is spreading to other regions, although no definite steps have been taken by the men requesting an increase.

In the exclusively brokerage trade the houses still appear to be able to secure a limited amount of coal, and it is believed that a very large proportion of this is procured by direct solicitation in the region from the small mines, as much of the coal comes here loaded in box cars.

BALTIMORE

Supply of soft coal here better under the zoning plan, but cause seems a little irregular. Plan to have a hard coal order week interests trade.

Bituminous—There can be no doubt that the supply of bituminous coal here is at present considerably better than for some time past. In a general way the officials of the fuel administration and coal men aiding in the fuel distribution work are attributing it to the operation of the zone plan. The particular situation here, however, has had a rather odd influence in the fact that it is reported that large quantities of soft coal which reached the redesignating points in the Cumberland gateway were diverted here because they had originally been loaded for New England points under the zone ban. This influx of coal here, combined with some little that came through under direct consignment, was sufficient to give all the piers and line terminal points in this vicinity a busy week. A large quantity of fuel was handled for the Shipping Board, and the extra handling caused the Government to operate the Locust Point pier to such an extent as to practically preëmpt it for the week. This pier of the Baltimore & Ohio is usually the local harbor distribution point because of the fact that when the Western Maryland at Port Covington, or the Baltimore & Ohio pier at Curtis Bay, is used there is a considerable extra towage charge. No one seems to kick at extra charges just now when coal is badly needed, however, and the influx of fuel was readily cared for. While there is some ease-up in railroad congestion between this city and the mines, conditions are still far from satisfactory and much more coal could readily be absorbed here.

Anthracite—There is general interest here in the project to have a week set aside for the placing of domestic orders for hard coal. A good proportion of the business is already on the books, as a result of urging by the Fuel Administration, much more indeed than there is any possibility of covering even by two-thirds delivery before the end of June, but the effort to have practically all orders put on the books before midsummer is nevertheless generally approved. Even if it is not delivered before the fall it will give a line on what the coal men here will need in greatest bulk. Meanwhile deliveries here continue light.

Lake Markets

PITTSBURGH

Car supplies still far below requirements. Steel mills disposed to stock coal.

Car supplies at Pittsburgh district mines are showing but slight improvement, at long range, and from week to week there is but little perceptible difference. The general testimony is that supplies are quite insufficient for capacity production of coal in the district, and also quite insufficient to give all consumers the amount of coal they would readily take. The current needs of consumers are being well taken care of, but there is little excess for stocking purposes. While domestic consumers may need considerable urging on the part of the Fuel Administration to lay in stocks this spring against next winter's requirements, the steel industry requires no urging, but is anxious to accumulate stocks for power purposes, gas production and byproduct coking. Especial attention is being given to gas coal, for the mills had some particularly trying experiences last winter, when it was difficult to secure absolutely needed gas coal, the authorities apparently being unable in all cases to grasp the distinction between gas and steam coal. The Government steel inspectors, however, did not relax their diligence, and some mills had a hard time trying to use high sulphur coal for gas production at openhearth furnaces and still keeping the sulphur in the steel down to the requirements of the specifications for Government steel.

Occasionally there is coal to be had through brokers, who are fairly busy doing a maximum amount of work on a minimum amount of tonnage, as transactions are put through with much more difficulty than formerly. The market remains quotable at the set prices: Slack, $2.20; mine-run, $2.45; screened, $2.70, per net ton at mine, Pittsburgh district, with an extra allowance of 15c. which brokers are allowed to charge.

TORONTO

Coal situation unchanged. Dealers overwhelmed with orders which they cannot fill. Receipts light. Wood to be largely used as substitute for coal.

The coal situation remains practically unchanged. Owing to the determination of consumers to lay in their supplies for next winter early, the dealers are overwhelmed with orders which cannot possibly be filled for some time. Deliveries are generally confined to small lots sufficient to meet present requirements. Receipts by rail continue light owing to the quantities being shipped by water to western points. The question of providing substitute fuels is receiving much attention. The provincial Department of Lands, Forests and Mines is letting contracts for cutting 25,000 cords of hardwood in Algonquin Park for the supply of public institutions, and several cities are arranging for supplies from the same source.

Quotations per short ton for best grades are as follows: Retail anthracite egg, stove, nut and grate, $10; pea, $9; bituminous steam, $8.50; slack, $7.50; domestic lump, $10; cannel, $13. Wholesale f.o.b. cars at destination three-quarter lump, unprepared, $6.11; prepared, $6.31; slack, $5.18.

BUFFALO

State of coal trade not much changed. Dealers find bituminous hard to get, but the demand is rather light. The opinion continues that present conditions give no chance to jobbers. Heavy demand for anthracite.

Bituminous—The supply is light, but the demand is not heavy as the consumers do not generally follow the plan of the consumers of anthracite in insisting on stocking up all they can get. It is reported that the railroads have gone into the market more largely within the past few days, and if that demand continues it will take care of any surplus coal that may be on the market. Buffalo is well supplied, but there is no coal waiting on track. The situation here is easy all around, though the future of the jobber is still in doubt. Few if any of them are doing a normal business.

The reports of congestion in Canada continue, though it appears that shipments there will hold up awhile, at least till the coal on demurrage is sold. Much money has been lost by the effort to secure the seller's margin of 30c. a ton which is allowed there instead of the 15c. here. Quite a good many Buffalo jobbers have set up a Canadian office, mostly in Toronto, where the effort was to meet the demand on a basis that promised a little profit, but it was soon so badly overdone that it is doubtful if much advantage was gained.

The Allegheny Valley price of $4.45 for all sizes has not made coal plenty there, all reports agreeing that it is still scarce. Pittsburgh prices remain at $4.25 for lump, $4 for mine-run and $3.75 for slack, all per net ton, f.o.b. Buffalo.

Anthracite—The local supply keeps up at about par with former seasons, though it is of course far short of the demand, which would cover the entire year's needs if it could be done. No consumer is at all satisfied with the normal amount, and but for the regulation forbidding the distribution in any but a horizontal way, the coal would soon be a cellarful here and nothing there. Outside shipments, especially to Canada, are taken care of by the shippers

in the same way. They see the impossibility of preventing suffering in secluded districts, unless the supply now going out is divided so that nobody gets more than a just proportion.

The lake trade is not very active yet, but the heaviest shipper has not loaded anything so far, though preparing to do so now. For the week the amount was 67,850 net tons, of which 27,100 tons cleared for Duluth and Superior, 19,400 tons for Milwaukee, 8000 tons for Sheboygan, 7300 tons for Green Bay, 3050 for Lake Linden and 3000 tons for Hubbell.

Rates are unchanged at 55c. for Milwaukee, 50c. for Sheboygan and Green Bay, 48c. for Duluth and 45c. for Lake Linden and Hubbell.

DETROIT

Receipts of bituminous and anthracite continue below normal. Detroit Board of Commerce investigates margin controversy.

Bituminous—While Federal and state fuel administrators are supporting the campaign to induce consumers of steam and domestic coal to buy now, in providing for their next winter's requirements, the movement of bituminous coal into Detroit continues to fall short of shipments in preceding years at this time. The amount of coal received at present, according to some of the jobbers, is considerably less than should be coming to Detroit to provide for current requirements.

The supply of slack seems less plentiful than would be desirable, though it is expected the loading of lake coal will improve the situation shortly. The diminished volume of receipts is attributed largely to the deficiency in supply of railroad equipment for its transportation. The shortage of cars, which has been a troublesome factor in the market for months, has been made more pronounced by the needs of lake shippers, which has resulted in diversion of cars and motive power to facilitate and expedite movement of coal from mines to loading docks.

Detroit Board of Commerce has been probing merits of the controversy between W. K. Prudden, Michigan fuel administrator, and Detroit coal dealers in reference to the fuel administrator's insistence that a $2.50 margin is adequate for the dealers for delivery of domestic coal during the summer months.

Anthracite—Few of the Detroit retailers have anthracite in stock and in none of the yards is there any substantial amount. With household consumers clamoring to have orders for next winter's supply filled, the dealers are, in many instances, refusing to accept orders for hard coal, owing to uncertainty as to what supply they will obtain and when it will be provided.

Lake Trade—Coal loading docks on Lake Erie are dumping into lake freighters an average of about 700,000 tons a week. It is calculated that the quantity loaded should amount to about 1,000,000 tons a week, if plans of the shippers for supplying the Northwest before the coming of freezing weather, are to be realized. The supply of tonnage offered for loading exceeds the cargoes. So far the movement of iron ore is light and freighters wait to load coal which, because of shortage of cars, is slow in arriving at the docks.

COLUMBUS

Better production of all sizes is reported from Ohio mining districts. Lake trade is increasing in activity, and domestic and steam demand remains brisk.

The Ohio coal trade has showed rather remarkable activity during the past week. According to reports from various districts the output has been increased to a more hopeful figure. Car supply is now better in all mining districts, and on the whole the outlook is rather cheerful. Demand for steam and domestic sizes remains strong, and strenuous efforts are being made to supply the domestic demand in order to avoid a repetition of the stress of last winter.

Retailers are busy making deliveries to householders, who are heeding the frequent warnings sent out by the Federal and State Fuel Administration officials. Hocking and Pomeroy grades are the principal varieties in the local market, although some Pocahontas and West Virginia splints are arriving. Consumers who have been waiting for the fancy grades are now buying Ohio coal more freely than formerly. A considerable tonnage of Pocahontas was received recently and this was quickly disposed of. Retail prices are firm at former levels. Anthracite is quite scarce and is selling between $11 and $12. Domestic coke is also higher.

Steam business is more active as large consumers are again in the market with orders intended for stocking purposes. The smaller steam users are buying for immediate needs only, as they believe that their requirements can be taken care of by the surplus over lake requirements.

Production in Ohio fields has been much better and a better feeling is shown in operating circles. Eastern Ohio, which has been lagging behind because of lack of cars, is now producing a considerable tonnage, estimated at 80 per cent. of capacity car ratings. The Hocking Valley is producing close to 90 per cent. and the same is true of Pomeroy Bend. Other fields are rather active.

Lake trade is becoming more active as the ice is now moving out of the upper lake passages rapidly. The vessel movement is better and considerable coal is now going to the Northwest. All of the lower lake docks have been busy loading bottoms. Docks in the Northwest are in good shape and little is being carried over from last season with the exception of mine-run and slack. Many permits have been issued by the Ore & Coal Exchange for the shipment of Ohio and West Virginia varieties.

CINCINNATI

Improving receipts, both by rail and river, and mild weather, have encouraged the trade. Deliveries on orders for current consumption and storage are progressing well.

While the car situation is not yet all that could be desired, judging by reports from both West Virginia and eastern Kentucky, the situation has still shown enough improvement, measured by actual receipts of coal on this market, to furnish much encouragement to the trade and to enable better deliveries to be made to customers. If receipts by local dealers will permit, it seems probable that the entire winter's supply of most domestic consumers, as well as of many large industrial consumers, will be in storage by the end of the summer season, which will be an absolutely unprecedented state of affairs. The favorable stage of the river is permitting arrangements for large shipments by that route to proceed, and river companies are taking advantage of the fact to fill their bins from their barges and thence deliver coal as rapidly as possible to customers. Nothing whatever is heard in the way of price discussion now, as consumers are aware of the fact that Government figures are the only ones to be had, and anxiety to secure adequate supplies of fuel overtops all other consideration. The situation is an ideal one for the trade, from almost every standpoint.

LOUISVILLE

Steam demand a little draggy, with domestic sizes in good demand. Excellent demand for gas coal and coal for by-products plants. Car supply improving.

In summing up the situation in Kentucky it is found that there has been an active demand for domestic and byproduct coal, but that steam has been a bit dull. However, business is active as a whole and operators are not making any effort to accept more than about 5 per cent. of the new business that is now being offered, as many have contracted up in fair shape. In western Kentucky there has been a more active demand for steam coal than in eastern Kentucky.

The car situation has shown some improvement in eastern Kentucky, where about 60 per cent. of requirements is now being had. In western Kentucky about 45 or 50 per cent. of the needed supply is being received. There are inequalities in distribution, but that apparently can not be helped at this time. Much labor has gone to the farms, and the mines as a whole are probably held back about 10 per cent. on account of the labor shortage.

No anthracite is on the market, and Kentucky is now on the anthracite barred list. Coke is also scarce and hard to obtain, although numerous metal-working plants are securing supplies by going into West Virginia for requirements.

BIRMINGHAM

Domestic consumers are now buying steadily and much coal is being stored for winter use. Priority regulations made more stringent. Both domestic and steam supply continue far short of requirements. Production hindered by irregular work.

Consumers of domestic coal have at last more fully awakened to the necessity of laying in coal for the approaching winter. Local yards are unable to handle the orders tendered, and their stocks are kept almost depleted by current demand. This is one encouraging feature in the face of the apparent inability of retailers to accumulate coal on their yards; they are selling it as fast as it comes in, and therefore it will not be necessary to accumulate the large stocks heretofore made available for the fall and winter demand. Another evidence of the activity on the part of the householders to provide against any possible future shortage is the large number of permits being issued by the fuel board for carlots to be prorated among community consumers. Dealers are able to make but few contracts with the mines and therefore cannot promise definite deliveries to their customers.

The situation in the steam trade has been intensified further by instructions from the Fuel Administrator that any surplus over and above the full requirements taken by essential or priority consumers must be held subject to disposition as directed by the Government authorities. It would seem that this regulation will result in the gradual elimination of all nonessential industries from participation in the coal supply. The Southern Ry. during the past week took 47 per cent. of the output of the mines on its lines, which is an exceedingly heavy drain on the supply.

Production is heavy, but the tonnage taken out is not at all commensurate with the task that should be rightfully expected from the forces employed at the operations, and indifference and inefficiency are given as the prime factors responsible for this situation.

Coke

CONNELLSVILLE

Coke shipments increase slowly. Pig iron production increases more rapidly. By-product plants will help.

Car supplies in the Connellsville region continue to increase from week to week, on an average, but the increase is slow and the distribution through the week is quite irregular, works receiving more cars some days than they can load, and not nearly enough on other days. Such increase in car supplies as has occurred in the past three or four weeks has been due wholly to coke moving through more rapidly, and empty cars also getting better dispatch, so that the time of the round trip is reduced.

The slight increase in coke shipments has been attended by a proportionately greater increase in the production of pig iron, that being due to the furnaces now working to good advantage, while in the early part of the year the consumption of coke, per ton of pig iron produced, was very high, owing to irregular working, frequent bankings and poor quality of some of the coke, due to its having been held in ovens too long, awaiting cars. Pig-iron production in the country as a whole is now at the rate of over 41,000,000 tons a year, while late in January and early in February it was down to below a 30,000,000 rate. The Carnegie Steel Co. is operating 53 of its 59 blast furnaces, which is very nearly normal. It was down to 29 furnaces for a few days early in the year.

When the Clairton, Cleveland, Lorain and Ironton byproduct plants are running full, within a very few months, there should certainly be an ample supply of coke. The first three are Steel Corporation plants, Ironton being a merchant proposition, which has been making ten-year contracts with blast furnaces in the district.

Very little Connellsville coke is finding its way to the open market, shipments being readily absorbed by contracts. Some of these are at flat prices, averaging about $8.25, while some are based on the prevailing market and thus are settled at the Government price. The market remains quotable at the Government limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over 1-in., $7.30, per net ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended May 3 at 333,455 tons, a decrease of 10,410 tons. Returns of rail shipments are temporarily interrupted. River shipments are given at 16,120 tons, against 17,620 tons the week preceding.

Buffalo—The movement of coke is light. Jobbers get no business as between the ovens and the furnaces, as there is no margin for them, so the furnaces buy of the ovens direct. The local byproduct coke plants are selling quite an amount of their surplus, partly at least through the jobbers, which competes with the regular bee-

hive coke. A considerable amount of fine "breeze" coke is also selling to steam plants, being obliged to compete with the small sizes of anthracite in that trade.

Birmingham—There is no change to be noted in the local coke market. Strong inquiry continues, but the supply of both furnace and foundry coke is short for the spot trade. Production is fair but not up to normal capacity. The supply of both rack and box equipment is satisfactory, and delayed deliveries are being caught up with rapidly.

Middle Western

GENERAL REVIEW

Size coal demand continues to be firm. Screenings and washed No. 5 moving slowly.

Well-prepared size coal is in unusually good demand throughout the Middle West. In fact in most all sections there is a struggle by the operators to come within gunshot of being able to produce anything like enough to supply their customers. Sections of the country that will be outside the zone limit after Nov. 1 have made, and are now endeavoring to get, a year's supply within the time limit. Former claims that they could not store coal seem to have been swept aside, and unusual activity is apparent. During the past week several large buyers from Minneapolis and St. Paul, Minn., have visited mining fields in their endeavor to pick up any loose coal. Fine coal has been soft the latter part of the week. However, little alarm is noticed, and the general feeling is that a better market is near for screenings and No. 5.

Labor conditions are still bad, and railroad equipment is short. Never in the history of some of the oldest mine men has there been so much grip and pneumonia as has prevailed throughout the coal field during the past month, and coal miners seem to have been special victims. Quite a number of deaths have been recorded. Coal-car equipment continues to be distressingly short in many localities, but as a whole transportation conditions show an improvement over corresponding weeks last year.

MILWAUKEE

Coal matters exceedingly quiet. Orders for future delivery coming in slowly. Organized effort to stimulate this phase of the coal problem.

Matters in the coal line are exceedingly quiet at present. Raw spring weather keeps dealers busy delivering small lots to piece out the waning season, but orders for next winter's supply are not coming in as freely as the coal administrators desire. It will follow psychologically, however, that when fires are out for good and bins are empty there will be a deluge of urgent calls. It would help matters in this respect if the summer schedule of prices were promulgated.

Interest just now centers in the coming supply. Since last week's report 12 cargoes aggregating 97,366 tons have reached port. Of this amount 20,366 tons were hard coal. The receipts for May, thus far, total 228,083 tons, of which 47,602 tons were hard coal.

Gov. E. L. Philipp, State Fuel Administrator W. N. Fitzgerald and Mayor D. W. Hoan have been in conference regarding the coal supply for next winter, and as a result there will be a meeting of representatives of the heavy coal-consuming counties of the state in the near future. Leading coal handlers will be invited to attend and discuss the matter from their viewpoint. Letters will also be sent to every business concern in the state urging them to get in their coal orders as soon as possible. It is believed that enough wood has been cut to run the creameries and dairies of the state during the coming winter.

Kenosha, Wis., has appropriated $20,000 for the establishment of a municipal coal yard. It is expected that 45,000 tons will be handled during the coal-burning season. William Rahr, Jr., has been named fuel administrator of Manitowoc County.

CHICAGO

Domestic demands continue to grow. Screenings easy.

The Chicago market has not shown any marked changes within the past week. The domestic demand has been growing and the steam demand is about stationary, as is also the car situation. The efforts of the Cook County fuel administrator to start a storage movement in many of the industries gave the steam demand quite an impetus, and has had a helpful influence. The anthracite situation is not as encouraging as it might be, the large companies that were able to get considerable coal last year at this time, having to content themselves with a much reduced tonnage, delivered in small lots, with a promise that more will be available later in the season. Retail dealers are not accepting orders for hard coal, simply noting them with the hope that their supply will be increased prior to the winter season. The ultimate users to some extent do not feel warranted in allowing their orders to stand and are willingly accepting anything they can get, whether it be anthracite or bituminous.

Because of the free movement of size coal, some of the larger users of screenings have thought that they would be able to break the screenings market and have put considerable pressure in this direction by refusing to buy, claiming they were loaded, when really they should have been absorbing all that was offered. No headway was made, and many of those that refused to buy two weeks ago are now in the market.

Quotations in the Chicago market are as follows, per net ton f. o. b. cars at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Springfield	Carterville	Grundy, La Salle, Bureau and Will
Steam lump	$2.65@2.80	$2.65@2.80	$3.05@3.20	$2.65@2.80	$2.65@2.80	$3.35@3.50
Domestic lump	2.65@3.00	2.65@3.00	3.05@3.20	2.65@3.00	2.65@3.00	3.35@3.50
Egg or furnace	2.65@3.00	2.65@3.00	3.05@3.20	2.65@3.00	2.65@3.00	3.35@3.50
Small egg or nut	2.65@3.00	2.65@3.00	3.05@3.20	2.65@3.00	2.65@3.00	3.35@3.50
Stove	2.65@3.00	2.65@3.00	3.05@3.20	2.65@3.00	2.65@3.00	3.35@3.50
Chestnut	2.65@3.00	2.65@3.00	3.05@3.20	2.65@3.00	2.65@3.00	3.35@3.50
Pea	2.65@3.00	2.65@3.00	3.05@3.20	2.65@3.00	2.65@3.00	.....

ST. LOUIS

An improved situation on everything excepting steam. Car supply short in the Carterville field and transportation poor, with same condition to a lesser extent in other fields. Shortage of men, prevalent everywhere, causes decreased production. Domestic sizes in demand, excepting Standard grade. Light anthracite shipments.

Local conditions continue to show improvement except that the shortage is more acute, with nothing to indicate that there will be any relief. The domestic business continues to come in in greater volume than anticipated, with the exception of Mt. Olive and Standard coal, orders far exceeding the available supply.

Steam coal continues to drag, especially on screenings and the smaller sizes of nut. There is, however, a chance that this condition will get relief on account of the numerous railroad orders for mine-run being placed, which will lessen the production of domestic sizes, and consequently bring about a shortage of screened coal. The situation would be much better if a larger tonnage of the Standard field were mine-run, and this is likely to be the case in the future.

In the Carterville field the tonnage is light on account of labor shortage. Car supply is extremely poor and transportation is far from what it should be. Many of the mines are refusing to accept orders because they are already oversold, and there is no relief in sight for easier conditions here. The same condition is prevalent in the Duquoin field.

Mt. Olive conditions are perhaps the most satisfactory of any. The working time is good, car supply is better than it has been for a long time, and the movement of coal in this field seems to improve. The tonnage just about takes care of the demand.

The Standard field presents an entirely different problem, and the only thing that has prevented a panic here is the fact that the railroads have been buying heavily on mine-run.

Steam sizes in this field are unusually heavy and restrictions on equipment, even under the Government supervision, are unfair and have kept coal out of territories needing it and crowding into territories that cannot use it.

There has been little anthracite coming in, and local conditions are satisfactory, with the exception that there is a demand for Carterville field that is causing anxiety on the part of those who have sold ahead.

The circular here is per net ton f.o.b. mines:

SEATTLE

Washington mines will not be able to meet demands. Greater increase in consumption than production aggravated by withdrawal of fuel oil.

Estimates of the production of coal mined in this state this year as compared with the estimated consumption, together with the prospect of heavy withdrawals of fuel oils, indicate that contrary to expectations Washington mines will not only be unable to ship coal to Montana and Oregon, but will not be able to supply the needs of consumers in this state this fall and winter. Last year this state produced 4,002,749 tons of coal and consumed 4,161,402 tons, of which 356,000 tons were imported from British Columbia and the East. As over 150,000 tons of Washington coal were shipped to Montana, Idaho and Oregon, the mines of the state more than cared for local demand. But such is not the case this year. The estimated production is 4,600,000 tons, an increase of practically 600,000 tons this year, with a consumption of 4,836,800 tons, an increase of 675,000 tons. The state cannot expect very heavy importations from British Columbia, for the Province finds itself facing a similar problem—increased consumption as a result of industrial expansion and the withdrawal of fuel oil.

Recently the tanker "Schofield," with a capacity of 100,000 barrels of oil, was withdrawn from the local field, and advices state that two more tankers will be taken into the Government service before the close of the month. On top of the withdrawal of tank steamers which has been occurring for months past comes a reiteration of the statement from oil authorities in California that the supply in the South will not be large enough to meet demands. Within a year a daily shortage of 50,000 barrels is predicted. Anticipating this the fuel administrator's office here has urged the conversion of oil burners to coal with the result that a greater task has been placed upon Washington mines than they can fulfill. Indications are that Washington will be at least 250,000 tons shy on demand in this state, and how much more rests entirely with the amount of oil that is to be withdrawn. Coal producers, heads of industrial plants and transportation men conservatively estimate that before the winter is done fuel oil to the equivalent of 500,000 tons of coal will have been withdrawn from the local markets.

COAL AGE

Volume 13 NEW YORK, MAY 25, 1918 Number 21

Progressive Coal Plans

By Floyd W. Parsons

RAILROADS and power plants of the United States have made it a rule to burn the very best coal that they could obtain. Now that the Nation is at war, this practice must cease, and Uncle Sam's locomotives, as well as many industries, will have to use coals of a somewhat lower grade.

The reason for this necessity is the scarcity of fuel specially adapted for byproduct plants, metallurgical purposes, ship bunkering and domestic consumption. When the railroads, or other consumers, take their needed tonnage from coal particularly suited for the foregoing purposes, a crime is committed against the Nation in its hour of need.

Marine boilers give highest service when burning a low-volatile coal. Such fuel not only adds to the speed of our naval vessels and transports, but it is smokeless, and thereby less likely to attract the submarine assassins. In this grade of fuel the navy's needs are paramount, and all other consumers must come second.

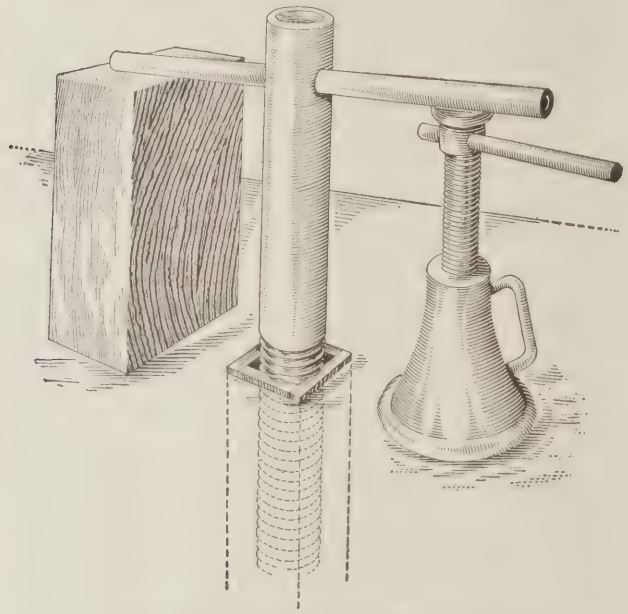
Metallurgical works and coke ovens are essentially war plants today. They must have, as a rule, a high-volatile coal running very low in sulphur. Railroads are particularly fond of this grade of fuel; however, there can be no question as to who must get it. All locomotives should be furnished high-volatile coal, and it must be decently prepared; but there is no reason why the railroads should insist on having the best our mines produce. It is also necessary that gas works and retail coal yards get their proper share of those coals suited to fill these special needs, for our domestic life must go on.

This is no time, of course, to undervalue the importance of transportation. The problem is very like our food problem. We must live, but we can get along without all-wheat bread. The railroads, and many other consumers, can get along without using coal that is sorely needed to safeguard our ships and to manufacture war supplies.

Mr. McAdoo is still indisposed. The railroad-fuel question remains unsettled. Dr. Garfield has appointed Walter A. Marsh, formerly general manager of sales for the Pittsburgh Coal Co., to the position of manager of the railway fuel division under Mr. Morrow. It will be Mr. Marsh's job to see that certain coals go where they are best suited and most needed. This is quite a step forward and should help the situation materially.

It is already certain that next winter will usher in a serious fuel situation. There is real reason to believe that the present weekly production of coal is near maximum, and if that is true, the output for the year will fall far short of estimated requirements. There can be no such thing as "business as usual" if we carry through our scheduled war program.

Among other problems Mr. Marsh will have to discover a solution for the difficulties of coal users in the Middle West. In Chicago and the territory adjacent, past winters have witnessed the consumption of much anthracite and a considerable quantity of low-volatile bituminous coal. The consumers in this Middle West region have base-burner stoves and furnaces designed to use these high-grade coals. Just how they will be able to burn Southern Illinois coal without altering present facilities is something worth knowing.



Wise people will now get what coal they can as quick as they can They will also make the necessary changes in their homes and their plants to burn the particular grade of fuel that is to be allotted for their needs. Don't be deceived into a sense of security by present summer breezes.

IDEAS AND SUGGESTIONS

Removing Bolthole Forms

BY L. V. LAUTHER
Guttenberg, N. J.

The wooden forms sometimes used for making the holes for bolts in heavy concrete foundations are often difficult to remove. In many instances such forms are made of rough lumber to which the concrete adheres

DEVICE FOR PULLING FORM BOXES

tightly. Even if made carefully of dressed boards coated with paraffine and slightly tapered, the boxes will sometimes stick tenaciously.

The accompanying illustration shows a means of pulling such form boxes. It consists of a piece of pipe of suitable length provided with a coarse thread and of such diameter that this thread will cut or "bite" deeply into the inside of the forms. After the pipe is screwed into place it may be pulled from the hole, bringing the wooden form with it, by means of the lever and jack as shown, or a clevis may be attached to its top and a set of chain blocks or a portable crane be used for lifting. In some instances a crowbar or other lever might be used to advantage.

Measuring Coal Areas and Making Coal Summary Sheets

BY "MINING ENGINEER"
Scottdale, Penn.

For the purpose of keeping a record of the area of coal already mined as well as that in process of development and recovery, it is necessary to use a fairly exact and rapid system of map measurement at least once a year. The system here described is exact to a reasonable degree, and in addition to being rapid is easily checked.

The mine map is divided into two parts—namely, gob areas and narrow work. A planimeter is used to measure the gob area in the usual manner, and this needs no description. A specially constructed scale is used for the narrow work. By narrow work I mean all excavations made by headings, rooms, cross-cuts, etc. This scale is made of tracing cloth $\frac{1}{4}$ in. wide and 30 in. long, with divisions every $\frac{1}{10}$ in. This will give a 100-ft. scale that is 3000 ft. long with divisions every 10 feet.

Before measuring the narrow work, this must be divided into classes, each of uniform width. This makes it necessary to separate headings from rooms, and wide headings from narrow headings. I have arranged the classes of narrow work, as shown in Fig. 2, in a manner that would apply to a majority of mines. The widths have been obtained from widths measured in dozens of different parts of the mine; the lengths from actual measurements of the maps; and the

NOTE.—A chart of this kind should be made for every tract.

FIG. 2. CHART FOR SHOWING CLASSES OF NARROW WORK IN EACH TRACT

gob increase by measurements with a planimeter. Every office will have to adjust this classification to its own particular needs, as some mines drive headings of different widths, and some probably drive headings and rooms of the same width. The classification is immaterial so long as a standard or several fixed standards are adhered to.

Both for convenience in checking and for use on the summary sheet, as explained later, it is expedient to measure all maps by tracts. For instance, taking the Johnson Tract, measure all headings of a certain width in it, being careful to exclude all work outside of the property line; do the same with all the narrow work and the gob area, and then start in on the adjoining tract.

How to Measure Narrow Work

To measure narrow work, taking roomwork as an example, place zero of the 30-in. tape on the face of, say No. 6 room, and laying the tape along the room towards the entry or room mouth, place a needle point on the 0 + 00 of the room. Now, keeping the needle point fixed on the tape at this point, slide the tape over to No. 5 room and measure it in the same manner as No. 6. Continue in this manner until all the rooms are measured. After noting the total reading on the tape, start in to measure the cross-cuts.

At this point it might be well to state that tinting of maps should only be done as often as the maps are measured, for it is much easier and more rapid if you know that the work to be included in the latest measurement is that which is not tinted.

To go to the trouble of making a yearly measurement and then not have it recorded in good shape on a coal-summary sheet would be a waste of time. The mining engineer is called upon daily to give an estimate of the coal already mined in certain tracts; to give an estimate of the coal remaining; to tell what township the tract is in; what acreage is barren, and what is unmerchantable coal; how many acres are held in reservations; what amount will be mined from one mine and what from another. Fig. 1 shows much indispensable information and is self-explanatory.

All data is expressed in terms of acres, unless otherwise noted, and the sheet should show the tons per acre for that particular mine. Solid coal is that coal which has not been developed by headings and rooms, and by coal remaining in ribs is meant that which has been developed and which lies between rooms, between headings, air courses, etc.

The amount of coal remaining in ribs which can be recovered will of course vary with regard to local conditions, but will approximate 85 per cent., and the tons per acre will likewise vary according to the height and character of the coal.

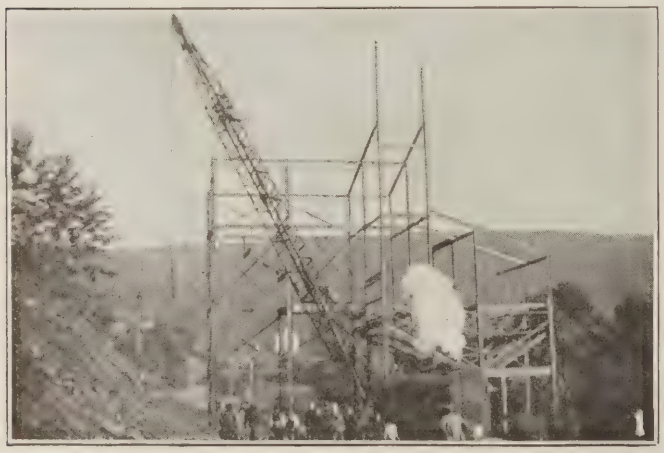
Shellac

By R. A. Lyons

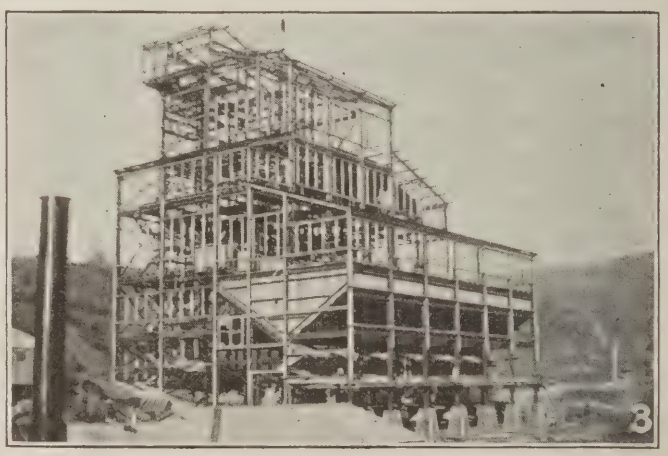
Shellac is one of the most valuable varnishes in use about electrical shops. It has the advantage of being a splendid insulator. It dries rapidly and it can be made almost any color desired. Shellac may be made by dissolving about 5 lb. of shellac gum in one gallon of 96 per cent. proof alcohol. This composition gives a rather thick mixture, which is desirable for painting coils, for insulation and like services, but it is too thick to use as a varnish, for which use it should be thinned.

In buying shellac gum, or resin, it is desirable to purchase a good grade. Frequently the shellac resin is adulterated with ordinary rosin, which is much cheaper and inferior in every way. The rosin adulteration can frequently be detected by crushing the mixture—the odor and feel of the rosin will then be apparent.

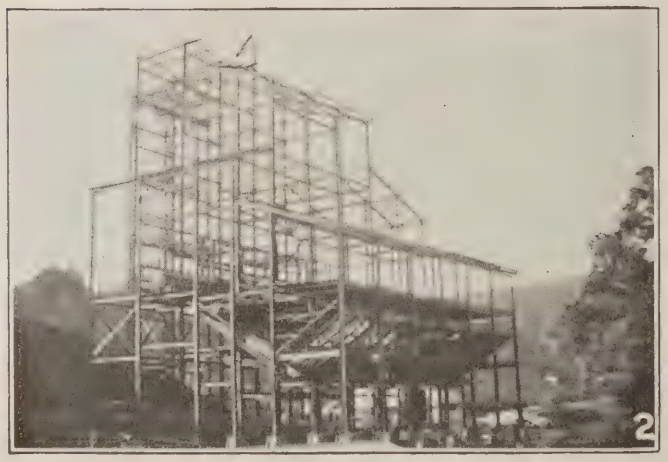
For coloring shellac varnish (which is to be used in insulating) black, one of the well-known makes of black, air drying, alcohol finishing varnishes should be used. It should be mixed into the clear shellac mixture to an extent that may be determined by experiment. Lampblack, which is finely divided carbon and hence a good conductor, should not be used in coloring shellac to be used for electrical purposes.



New Steel Washery of the Locustdale Coal Company



By WILBUR L. CROSS, Jr., E. M.
Superintendent, Locustdale Coal Co., Ashland, Penn.



DURING October, 1917, what is believed to be a record in the erection of the steelwork for any coal preparation plant in the anthracite region was made in the erection of the Locustdale washery for the Locustdale Coal Co., at Germantown, near Ashland, Penn. This structure, containing 437,500 lb. of structural steel, was erected by 10 men and a crane in 8 working days of 10 hours each. This time includes the unloading of steel from the railroad cars. Erection does not mean completion, for the steel framework of the structure was not entirely completed at the end of this time. All the bolts were not in place nor were they all tightened up. However, the pockets were completed so that the carpenters could start right in with their work of planking, and the men bolting up kept ahead of the carpenters at all times. Owing to the comparatively short life of the property, the steelwork was bolted together so that it could be taken apart easily when the bank was exhausted. The progress of erection of the washery is shown in Figs. 1 to 4, inclusive. Fig. 1 notes the amount of material assembled at the end of the first day; material erected at the close of the eighth day is shown in Fig. 2. Fig. 3 shows progress in pocket lining and studding for window sash. Some siding and sash are in place in Fig. 4. A general view of the washery and surroundings is given in Fig. 5. A detailed view of the washery framing, including the diagonal bracing, is illustrated in Fig. 8; some of the chutes, jig casing and other interior work are also shown.

The Heilner banks are being prepared by this washery, and they are located west of Ashland near Locustdale and Germantown, Penn., about one-half mile north of the Potts colliery of the Philadelphia & Reading Coal and Iron Co. They are the property of the Lehigh Valley Coal Co., but are being prepared by the Locustdale Coal Co. on a royalty basis.

These banks are not by any means "refuse," in the sense that this word is used today, for the coal was put down 50 or 60 years ago when standards were much different from what they are today. Tests of the coal prepared show that the broken coal and a good deal of

FIGS. 1, 2, 3 AND 4. LOCUSTDALE WASHERY AT DIFFERENT STAGES OF CONSTRUCTION
Fig. 1—Amount of material assembled at end of first day. Fig. 2—Material erected at close of eighth day. Fig. 3—Shows progress in pocket lining and studding for window sash. Fig. 4—Shows some siding and sash in place

FIG. 5. GENERAL VIEW OF LOCUSTDALE WASHERY

the egg coal found in the bank is either bony (which they throw out) or good coal missed in the former preparation. To some extent this is also true of the stove coal, although in this case a large percentage of good coal went to the bank with the bony. Nut coal is as clean as the average run-of-mine. Pea coal and buckwheat from the bank need not be jigged, as the slate percentage is far below the limit.

Due to peculiar surface conditions, it is necessary to load the bank into cars by means of a steam shovel; hoist the cars up a plane 700 ft. in length on a pitch of 14 deg.; thence by locomotive 3500 ft. to a trestle, located about 600 ft. west of and at the same elevation as the top of the washery. The cars are dumped here and the coal slushed down a chute of terra cotta pipe on a pitch of 2 in. to the foot, into the bottom of the ele-

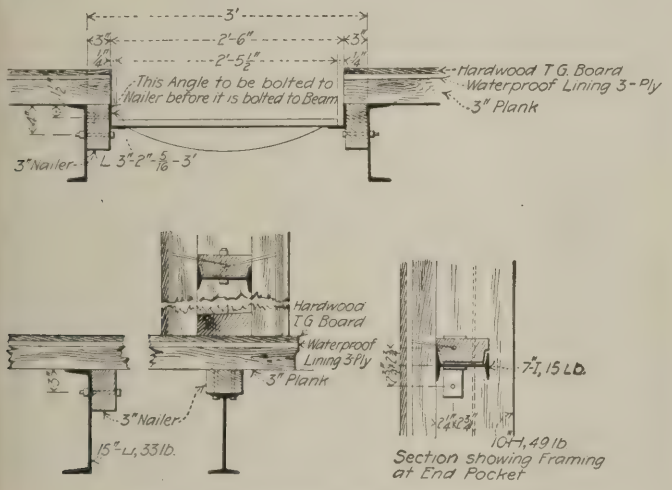


FIG. 6. DETAILS OF CONSTRUCTION

vators. To have delivered this material at the top of the structure in cars would have been the ideal plan. This could have been done, but only at an expense not justified by the life of the property. The trestle dump and slushing method has its advantages in that it permits the storage of a large quantity of material, thus allowing constant operation of and constant feed into the washery in case of delayed transportation or delays at the steam shovel.

Water for slushing and for use in the washery is obtained from the old Heilner mine workings, the original source of this coal. A Worthington type B. S. single-stage centrifugal pump delivers this water at the rate of 1000 gal. per min. against a total static head of 125 ft. through a 10-in. wood pipe to the hose used for slushing and to the tank in the washery. This pump is belt-driven by a 60-hp., 2200-volt, three-phase, 60-cycle slip-ring induction motor. With the exception of the steam shovel and locomotives, this operation depends entirely on electric current purchased from the Eastern Pennsylvania Light, Heat and Power Co. and uses 2200-volt motors.

The hoist used to pull the cars up the plane is an old balanced plane hoist put in for emergency use and geared to a 125-hp. Allis-Chalmers slip-ring 2200-volt motor. This hoists three cars of 120 cu.ft. capacity at one time on the level. A new Flory hoist now being

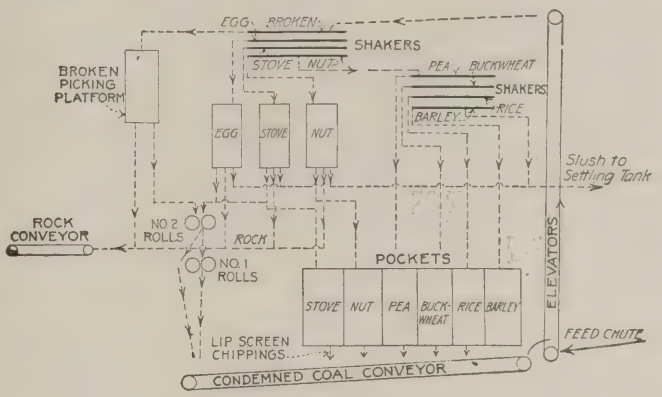

FIG. 7. LOCUSTDALE FLOW SHEET

erected will replace the old hoisting plant. It will be driven by a Western Electric 200-hp., slip-ring, 2200-volt motor and will hoist four cars per trip on the balanced plane.

The washery is driven by a 150-hp., 2200-volt, three-

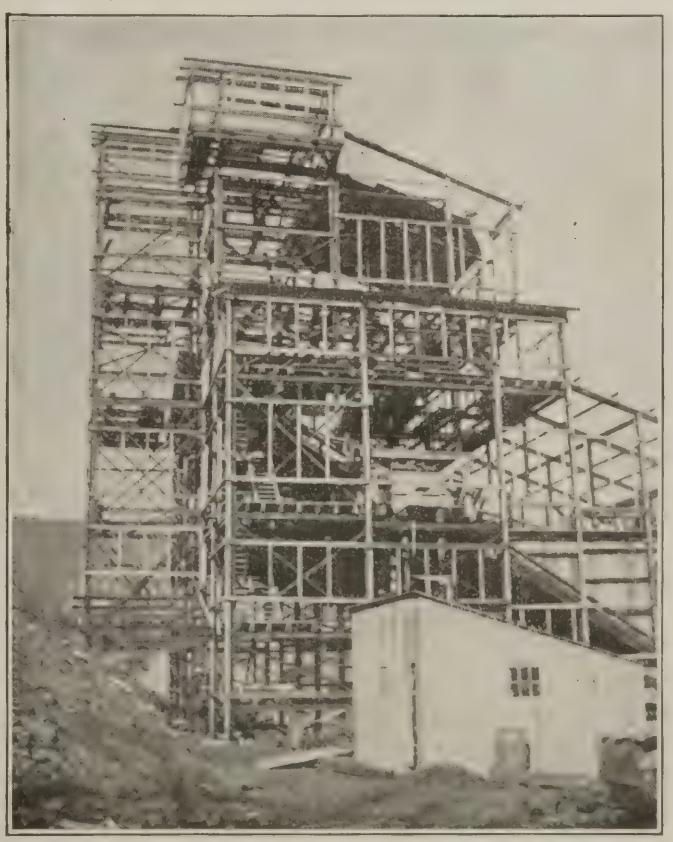

FIG. 8. DETAILED VIEW OF FRAMING

phase, 60-cycle, slip-ring Westinghouse induction type H. F. motor. This is rated at 37 amp. full load. To put coal through at the rate of 1000 tons per day requires from 100 to 125 hp. In starting under full load momentary overloads of from 200 to 250 per cent. are caused. This overload the motor carries without any trouble whatsoever.

The design of this plant, specifications for all machinery, motors, etc., and all details in the construction and operation of the plant were made under the direction of the writer. The maximum capacity of the plant is 1500 tons per day of 8 hours. The steelwork was designed by the Guerber Engineering Co., of Bethlehem, Pennsylvania.

The building is covered with corrugated iron and, as can be seen from the accompanying photographs, has a large amount of window space. Floors are of wood, as this is a fairly temporary structure, but all chutes and hoppers are made water-tight to prevent any water from coming in contact with the steel. Details of pocket construction and methods of attaching wood to the steel are shown in the accompanying sketch (Fig. 7). A longitudinal section of the washery showing the machinery in position is shown in Fig. 9.

All of the machinery, with the exception of a few pulleys, was furnished by the Wilmot Engineering Co., of Hazleton, Penn. The chain in the elevators is the extra heavy 9-in. pitch Keystone rivetless chain. The buckets are 30 x 24 x 15 in. spaced every 27 in. on this chain. The chain speed, originally 88 ft. per min., has been increased to 108 ft. per min. to take care of the excess water which comes down the feed chute with the slushed product. The distance center to center between the driving wheels at the top and the take-up wheels at the bottom is 81 ft. All gears, shafts and boxes are of extra heavy construction.

The elevators discharge their product over the top bank of four prepared coal shakers, making broken, egg, stove and nut coal. These shakers are of the standard Wilmot construction, wooden sides reinforced with angles. The arms are removable hickory spring pieces which are bolted fast to the sides of the shaker. The eccentrics have a 6-in. throw and are of extra heavy construction. A flywheel pulley on the shaker shaft helps wonderfully in maintaining a constant shaker speed under varying loads. These shakers are 24 ft. long, 5 ft. wide and are set on a pitch of 1 in. to the foot. Running at from 142 to 145 r.p.m. the 6-in. throw of the eccentrics keeps the shaker jackets reasonably clear of the long pieces of coal which ordinarily lodge in the holes in the jackets.

Large lumps of coal and rock are removed outside the washery by means of bars in the slush chute and do not get into the elevators. The product, therefore, of

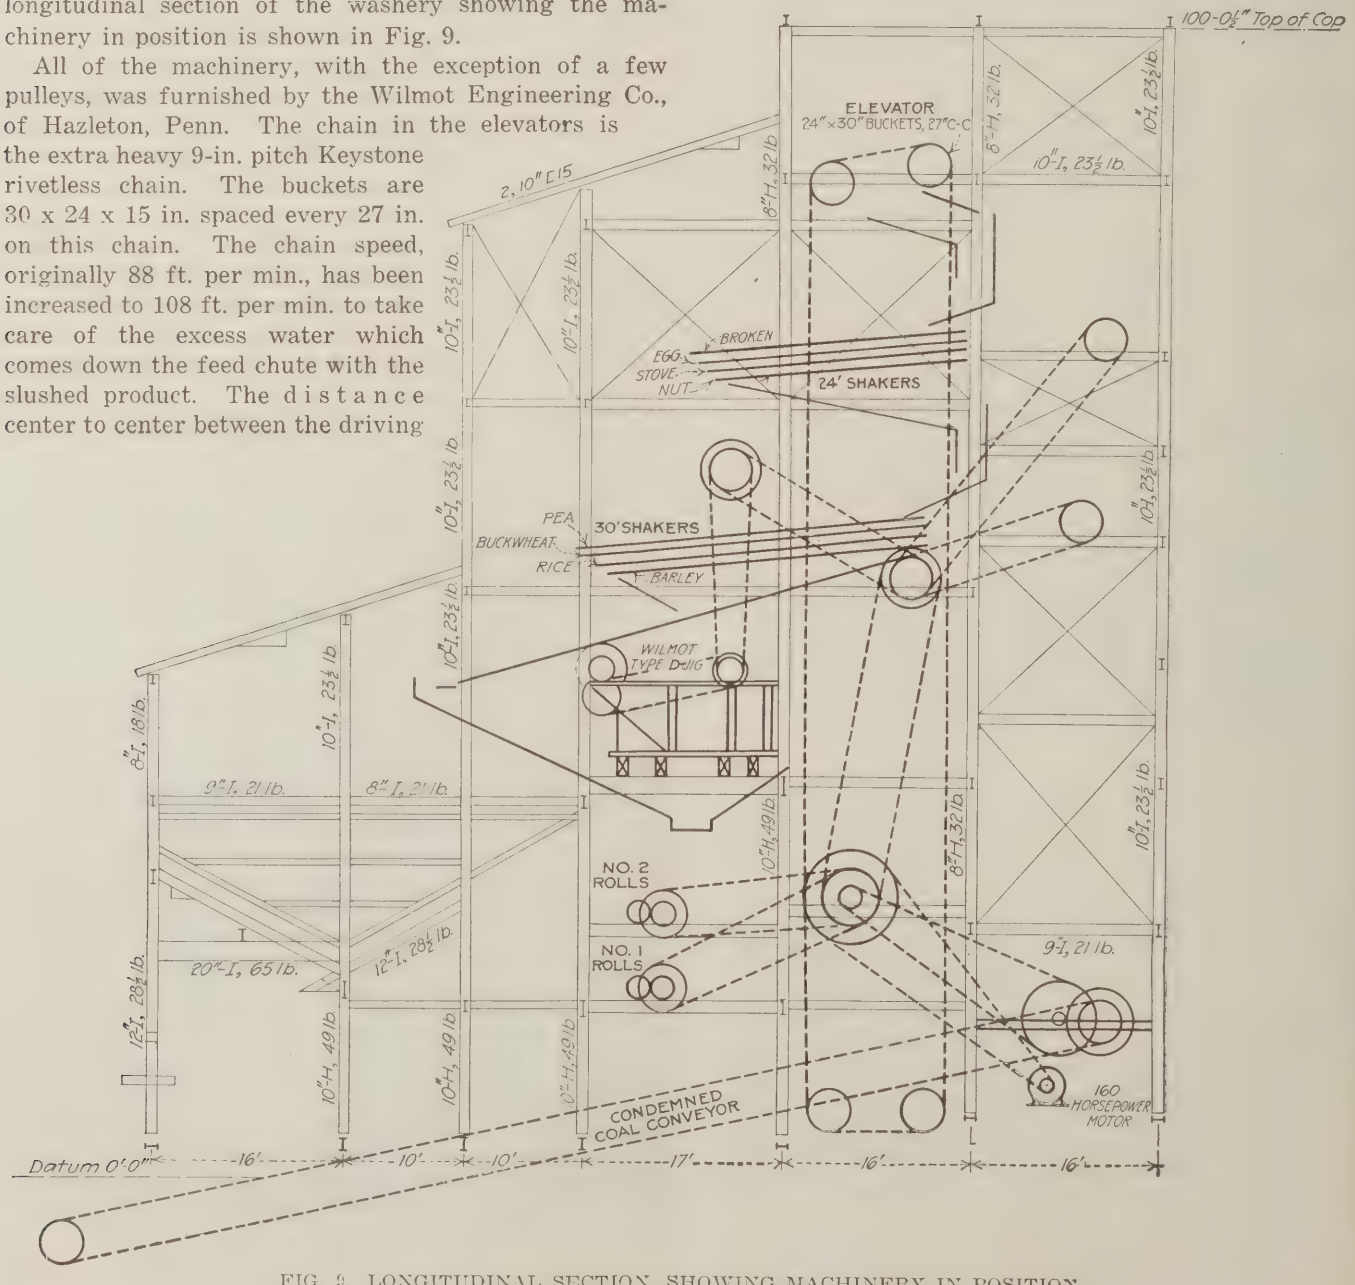

FIG. 9. LONGITUDINAL SECTION, SHOWING MACHINERY IN POSITION

the upper deck of shakers is broken and small steamboat. The percentage of rock is high and the tonnage low. Two boys pick the coal and bony from this size and send it down a spiral chute to the No. 2 rolls.

Egg coal has a large percentage of rock and bony coal in it. From the shaker it goes to the jig pockets and thence to two Wilmot type D Simplex jigs. Part of the coal delivered by the jigs goes to a small pocket for use in the locomotives. The remainder goes to the No. 2 rolls to be broken down. There is too much bony and flat coal of bad appearance in this size to permit of direct shipment.

Stove coal from the shaker goes to the jig pockets and thence to two Wilmot type D Simplex jigs. There is too much light bony and coal of a bad appearance in the jigged coal to permit of its being loaded under strict inspection. Two boys pick this bad stuff from the coal. The pickings are sent to the No. 1 rolls and broken to pea and smaller. Nut coal from the shakers goes in a spiral chute to the jig pockets, thence to three Wilmot type D Simplex jigs. The coal from these jigs is excellent and needs no picking.

The slush product from the upper bank of shakers goes to the lower bank of shakers—pea, buckwheat, rice and barley sizes. These shakers are of the same type as the prepared shakers but are 30 ft. long. The "Beaver" type of spray is used over all of the shakers. Pea coal, buckwheat, rice and barley from their respective shakers go direct to the pockets. Pea coal averages about 6¼ per cent. of slate, buckwheat rarely runs over 8 per cent., with rice and barley looking fine.

An inspection of the flow sheet (Fig. 7) shows that coal from the No. 2 rolls goes either to the condemned coal conveyor or is rebroken in the No. 3 rolls. There are certain parts of the bank which contain an unusual percentage of bony coal. When coal is coming from those sections, the broken and egg are put through both sets of rolls to keep the bony out of the stove and nut coal. Although it is not a good plan to run from roll to roll without an intermediate screening, this is done so infrequently and the character of the coal is such that there is really little if any loss. Coal from either or both sets of rolls goes to the condemned coal conveyor, discharging into the chute and elevators.

All of the rock goes to a common rock chute which discharges into the rock conveyor line. This line takes it across the railroad track to a hopper, from which it is conveyed in dumpers to the rock bank. Although the plant is run by electricity, a small boiler must be maintained during the winter for heating purposes. This boiler is supplied with boiler coal by means of the rock line during noon and after quitting time. This is done by having a removable pan in the rock line and a chute from this point in the rock line to the boiler house coal pocket. This plan saves an extra conveyor line. This conveyor line is made up of Wilmot light 9-in. Keystone rivetless chains with 8 x 18-in. flights. The plates in the bottom and sides are cast iron and are interchangeable. The condemned coal line is a duplicate of the rock line. This rock line, which is detached from the washery, is driven by a General Electric 35-hp., 2200-volt, slip-ring motor with variable speed control. It is 185 ft. in length, and when well loaded the motor is taxed to its full capacity.

The slush and water from the hopper under the lower deck of shakers flows into the main slush trough under the jigs, thence out to the slush bank. In the near future it will go to a settling tank now under construction.

The force on preparation is as follows: One breaker boss, 1 jig boss, 1 jig runner, 1 oiler, 1 machinery attendant, 1 motor runner, 2 pickers on broken coal, 2 pickers on stove coal, 1 cleaner up—a total of 11 men and boys. On the car road are 1 loader boss and coal inspector and 3 loaders—a total of 4 men.

The water for preparation is forced by the centrifugal pumps (previously mentioned) to a 5000-gal. wooden storage tank at the top of the washery. The four outlets are all 3-in. pipe governed by Eynon-Evans special brass body globe valves. Line No. 1 feeds the sprays on the upper shakers; No. 2 the sprays on the lower shakers; No. 3 the car road sprays and No. 4 the jigs. To save valves a trough was built behind and above the jigs, which is fed by line No. 4. A special inexpensive casting is inserted in this trough, and a wooden plug fits in this casting. By pulling the plug, the jig may be quickly and easily filled. An automatic arrangement was tried here depending on a float in the water of the jig. It was not satisfactory, owing to the continual disturbance of the jig water. With the trough on the same level as the jig, an admirable automatic feed can be easily installed.

Research Fellowships in the College of Mines, University of Washington

The College of Mines of the University of Washington offers five fellowships in Mining and Metallurgical Research in coöperative work with the Bureau of Mines. The fellowships are open to graduates of universities and technical schools who are properly qualified to undertake research investigations. The value of each fellowship is $720 per year of twelve months, beginning July 1, 1918. Fellowship holders are required to register as graduate students and to become candidates for the degree of Master of Science in Mining Engineering, or Metallurgy, unless an equivalent degree has previously been earned.

The purpose of these fellowships is to undertake the solution of problems in mining and metallurgy which are of special importance to the State of Washington, Alaska, and the Pacific Northwest. For the year 1918-1919 the following subjects have been selected for investigation: (1) Washington mining problems. (2) Ore concentration, including flotation and electromagnetic processes. (3) Electrometallurgy; electrothermic and electrolytic investigations. (4) Coal washing. (5) Utilization of the nonmetallic resources of Washington.

Applicants should send a copy of their collegiate records from the registrar's office of the college where they have been, or will be, graduated. They should also state their professional experience and give the names and addresses of at least three persons who are familiar with the character, training and ability of the applicant. Applicants liable for military service should state their classification and other pertinent facts relating to the draft. Applications are due not later than May 30, and should be addressed to the Dean, College of Mines, Seattle, Washington.

Graphic Determination of Prices

By J. D. SKINNER
Rocky Mountain Fuel Co., Denver, Colo.

SYNOPSIS—*Varying prices for the different sizes of coal produced at the mine make it advisable to be able to determine which should be sold—run-of-mine, or lump and slack. The accompanying curves make such determinations easy.*

WHEN varying prices are received for run-of-mine, lump and slack coal and certain percentages of the two latter are made, it is somewhat difficult to determine quickly whether it will be advantageous to sell the mine output with or without preparation. And in whatever condition the coal is disposed of, it is advisable to know both "why" and "how much."

To provide a means and basis for quickly comparing the prices of these three grades of coal and determining which will yield the greatest return, I have constructed the accompanying charts. These are based on the following simple calculations:

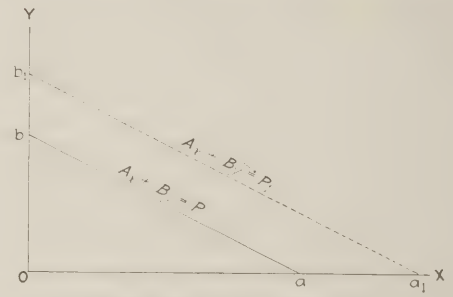
Let

P = Price of mine-run per ton;
x = Corresponding price of lump per ton;
y = Corresponding price of slack per ton;
A = Percentage of lump made;
B = Percentage of slack made.

Hence $A + B = 100$.

Problem—Given P, A and B to find x and y.

In one ton of mine-run there is an amount of lump represented by the decimal fraction A and an amount of slack represented by the decimal fraction B. Hence, when the portion A of a ton of lump is sold at x dollars per ton, and the portion B of a ton of slack is sold at y dollars per ton, the total receipts will be P dollars; and we have the relation



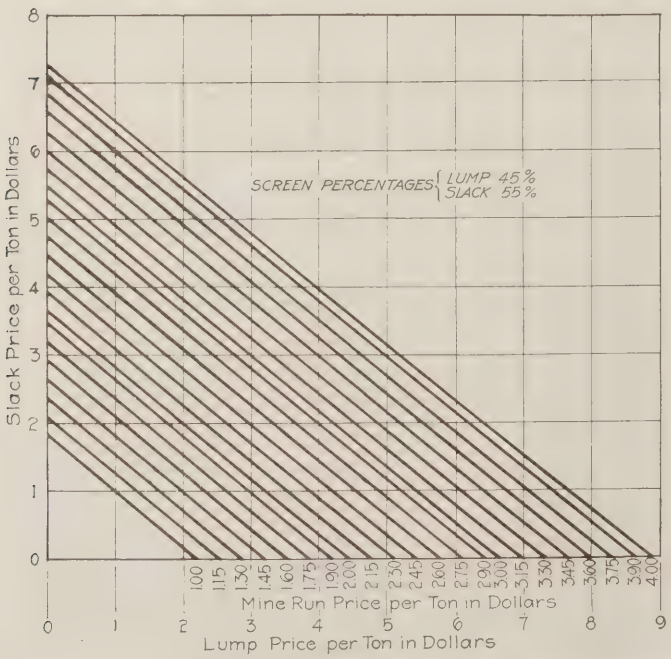
$$Ax + By = P \qquad (1)$$

Since equation (1) is of the first degree, its graph is a straight line.

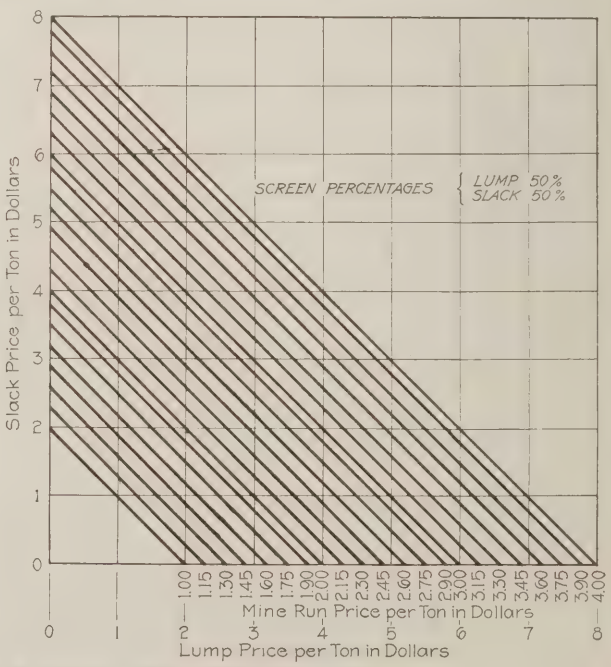
Letting $x = o$, the intercept on the Y-axis is $Ob = \frac{P}{B}$.

Letting $y = o$, the intercept on the X-axis is $Oa = \frac{P}{A}$.

Hence, for given values of A, B and P, the graph of (1) can be drawn by connecting the intercepts. If A and B are supposed to be constant and x and y have

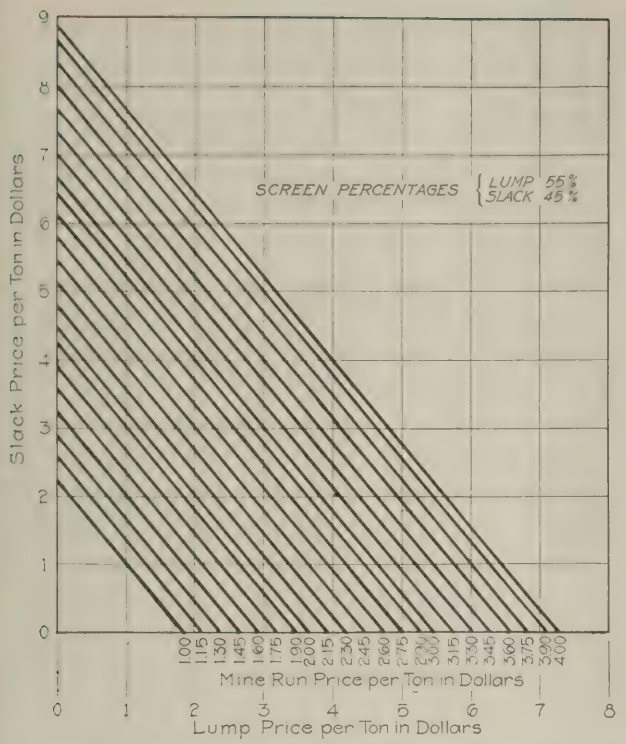


THE GRAPH OF EQUATION (1)



different values, a series of graphs may be constructed for different values of P. That these lines will all be parallel may be shown as follows:

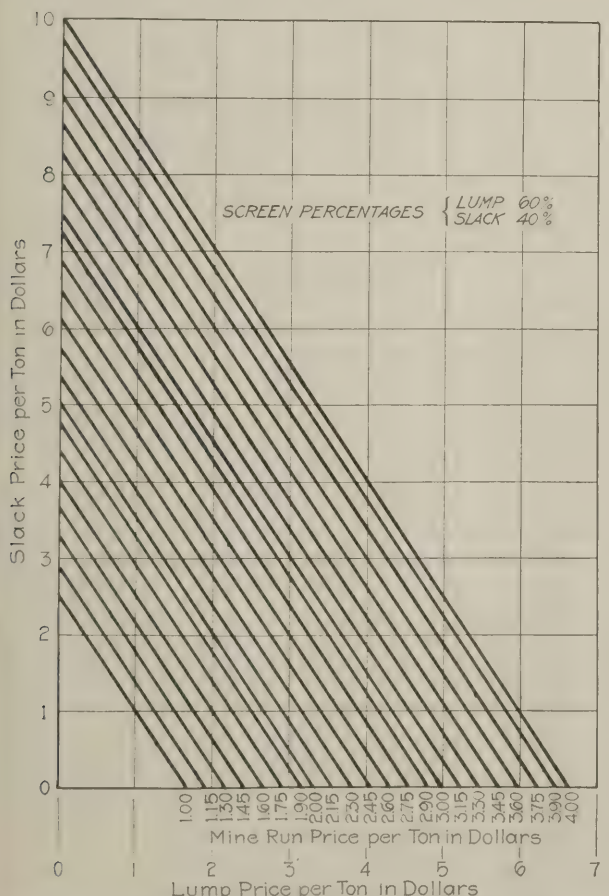
Transposing (1) and dividing both terms by B to put it in the slope-intercept form:



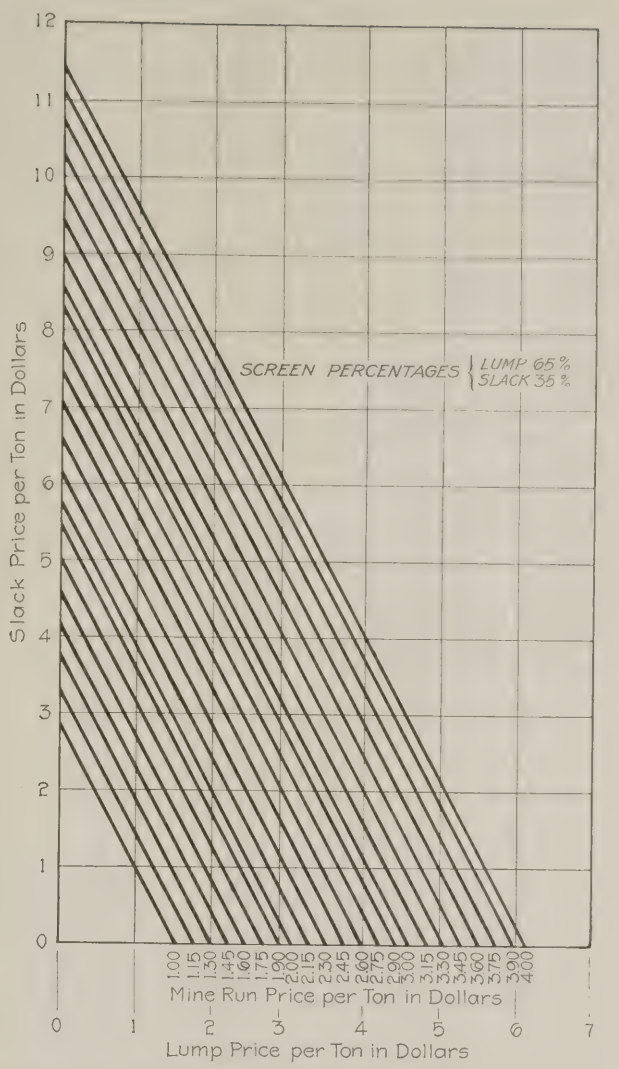
$$y = -\frac{Ax}{B} + \frac{P}{B}$$

Hence, the slope of (1) or $M = -\frac{A}{B}$.

COAL PRICES SHOWN GRAPHICALLY FOR 45 AND 50 PER CENT. OF LUMP



PRICE DETERMINATION FOR COAL CONTAINING 55 PER CENT. LUMP



Now the equation of any other line having a different value of P, say P_1, is

$$y = -\frac{Ax}{B} + \frac{P_1}{B} \qquad (2)$$

Since the slope of (2) is likewise $-\frac{A}{B}$, (1) and (2)

GRAPHIC PRICES FOR COAL CONTAINING 60 PER CENT. LUMP

GRAPHIC PRICE DETERMINATION OF A COAL CONTAINING 65 PER CENT. OF LUMP

make the same angle with the axis of X and hence are parallel.

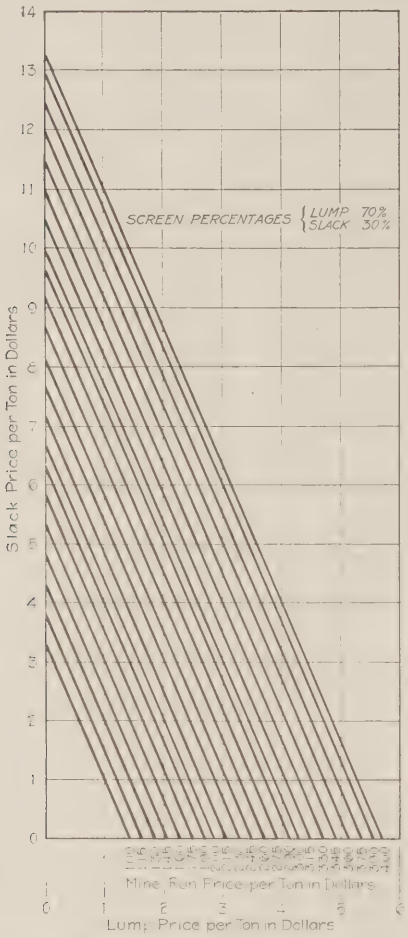
The following illustrates the method of finding the intercepts:

Screen percentages { Lump 70 per cent. Slack 30 per cent.

Hence $A = 0.70$ and $B = 0.30$

Price of Mine-Run P	Intercept on X-Axis $Oa = \frac{P}{A}$	Intercept on Y-Axis $Ob = \frac{P}{B}$
$1.00	$1.43	$3.33
1.15	1.64	3.83
1.30	1.86	4.33
Etc.	Etc.	Etc.

Method of Using the Diagrams



Example 1. Given cost of mine-run f.o.b. railroad cars at mine (including cost of screening lump and slack) = $2.30 per ton. Profit 15c. per ton. Selling price of lump f.o.b. mine $3.20 per ton. Screen product: 70 per cent. lump; 30 per cent. slack.

Find corresponding price, f.o.b. mine, that slack must be sold for in order that the combined profit on lump and slack will be 15c. per ton on a mine-run basis.

Solution—On the diagram for 70 per cent. lump and 30 per cent. slack follow along the diagonal line marked $2.45 (the selling price of mine-run) until it intersects the vertical line through $3.20 (the selling price of lump to the scale marked on the axis OY). The dis-

tance this point of intersection is above *OX*, measured along the line through $3.20 and perpendicular to *OX*, is the corresponding price of slack, which, by the scale on the axis *OY*, is $0.70. If the price of slack had been given instead, the corresponding price of lump could be found in a similar manner.

Example 2. Given selling price of lump = $4.10

GRAPHIC PRICE FOR MINE-RUN CONTAINING 70 PER CENT. LUMP

f.o.b. mine. Selling price of slack = $1.20 f.o.b. mine. Cost of mine-run (including screening, etc.) = $2.90 f.o.b. mine. Screen product 65 per cent. lump; 35 per cent. slack.

Find profit per ton of mine-run sold as lump and slack.

Solution—On the diagram for 65 per cent. lump and 35 per cent. slack find the intersection of the line perpendicular to *OX* at $4.10 with the line perpendicular to *OY* at $1.20. This point of intersection lies a little over halfway from the diagonal marked $3 to that marked $3.15, which gives $3.08 for the corresponding selling price of mine-run. Hence the profit per ton mine-run at the mine is $3.08 — $2.90 = $0.18.

Example 3. Given selling price of mine-run, including operator's profit = $2.90 per ton f.o.b. mine. No market for slack, which therefore has to be wasted. Screen product: 50 per cent. lump; 50 per cent. slack.

Find corresponding price, f.o.b. mine, at which lump must be sold to obtain the given price for mine-run.

Solution—On the diagram for 50 per cent. lump and 50 per cent. slack follow along the diagonal marked $2.90 until it intersects the axis *OX* (on which the selling price of slack is zero). This point of intersection is at $5.80, which is the required price of lump.

Mine-run prices between those given may be secured by laying a transparent ruler between and parallel to the proper diagonal lines and reading its intersections with the vertical and horizontal lines.

These diagrams also can be used to compute costs as well as selling prices.

Record Tonnage in British Columbia

By Robert Dunn
Victoria, B. C.

The demand of the Dominion authorities for more coal continues to meet with good response from the operators of British Columbia. The latest official returns show that the total output of coal for British Columbia for the first quarter of the year was 673,044 tons, which is a gain of 19,213 tons over the same period of 1917.

The production by districts is given as follows:

	Tons
Vancouver Island	425,759
Crow's Nest Pass	199,700
Nicola Princeton	47,585
Total	673,044

The production of the various companies was as follows:

	Tons
Vancouver Island:	
Western Fuel Co	198,467
Canadian Collieries (D) Ltd	189,560
Pacific Coast Coal Mines	25,779
Nanoose Collieries	11,953
Crow's Nest District:	
Crow's Nest Pass Coal Co	175,378
Corbin Coal & Coke Co	24,322
	199,700
Nicola Princeton District:	
Middlesboro Collieries	30,071
Fleming Coal Co	4,152
Princeton Collieries	13,362

The Vancouver Island collieries have produced upward of half a million tons during the first quarter in spite of the fact that three producing mines have closed down; namely, the Jingle Pot mine, which has not been operated on account of a fire in the underground workings; the South Wellington mine of the Pacific Coast Coal Mines, which, being worked out, has been abandoned; and the No. 4 mines of the Canadian Collieries, abandoned for the same reason.

The Western Fuel Co. produced 29,967 tons more in the first three months of 1918 than in the opening quarters of the previous year; the Nanoose Collieries show an increase of 9172 tons; while the output of the Canadian Collieries and the Pacific Coast Coal Co. has fallen off slightly. This, however, is expected to be more than offset by the opening of two new mines, which now are being developed and equipped, one at South Wellington by the Canadian Collieries (D) Ltd. and the other at Cassidy's Siding, Vancouver Island, by the Granby Consolidated Mining, Smelting and Power Company.

In the Crow's Nest District, the Crow's Nest Pass Coal Co. produced 24,708 tons more in the first quarter of this year than in the first months of 1917, while the Corbin Coal and Coke Co. also has increased its production to the extent of 8716 tons.

The collieries of the Nicola-Princeton District show a similar improvement, the Middlesboro Collieries were increasing their output 14,963 tons, although the Princeton Collieries have dropped about 3000 tons.

Pulverized Coal for Industrial Purposes*

By JOHN CUNLIFFE
Vancouver, British Columbia

THE employment of pulverized coal in various industrial processes offers many advantages over the use of other fuels. Industries of the western provinces of Canada that now rely largely on California crude oil will sooner or later, through stress of circumstances, be compelled to adopt some substitute. Of the available fuels powdered coal offers the most promising solution.

BROADLY speaking, coal may be described as the stored-up heat of the sun of former ages. To describe in definite words the meaning of the word "coal" is not simple. However, coal may be defined as a solid stratified substance, capable of undergoing combustion in contact with oxygen, and not containing sufficient earthy impurities to prevent its being applied as a source of heat in furnaces and fireplaces. It varies in color from brown to black.

There is nothing authentic in history to indicate by whom or how the heating value of coal was discovered. It was probably due to chance or accident, with all records lost in antiquity. The Indians of Nanaimo, Vancouver Island, knew of the heating power of coal many years before its exploitation there by white men, and termed it in their jargon "the black rock that burns." Further north on the east coast of that island the Indians discovered coal many years ago, and named the stream on which it was found "Suquash River." Interpreted, the Indian word "suquash" meant "the rock that burns." It is probable our ancestors discovered the heating value of coal in a similar manner.

The heating value of various coals was determined by scientists many years ago, and public attention from time to time has been called to the great waste in our crude methods of burning it. The furnaces and fireplaces of today are but little improved from those of our grandfather's time. It has remained for 20th century science to solve to some small extent this problem of waste. To illustrate how serious this waste is, let us take for example the case of steam generation and its application today.

Work Done by One Pound of Soft Coal

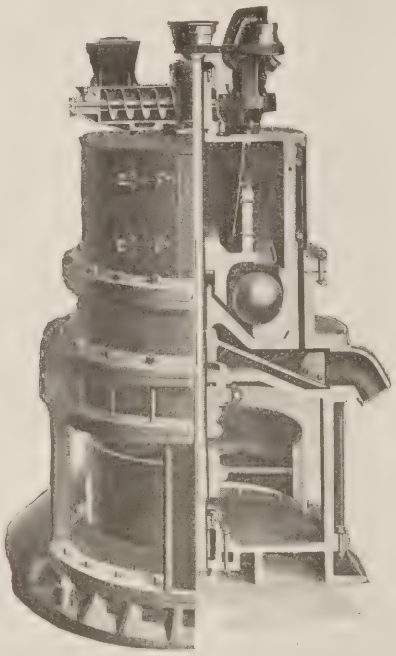
A single pound of good bituminous coal contains about 14,000 B.t.u. of heat, and each unit is capable of conversion into 778 ft.-lb. of mechanical work. The measure of mechanical work known as a horsepower is equal to 33,000 ft.-lb. per minute, or 1,980,000 ft.-lb. per hour. The heat units in one pound of coal, if it were possible to completely convert them into mechanical work, would equal 5½ hp.-hr. At that rate, 1000 hp. could be generated for 10 hours on less than one ton of coal. In practice, the best modern steam engines use from 8 to 10 tons of coal to maintain 1000 hp. continuously for 10 hours, and the average small steam plant requires from 20 to 30 tons or more.

The foregoing is only a single instance of the many waste problems engineers are grappling with, and hope to solve, or at least reduce as far as possible. The successful use of pulverized coal for industrial purposes is a step in the right direction. Its demonstrated safety and economy augur well for an early solution of a large slice of the vexed heat waste problem. The advance is made on correct principles, and as soon as the production and application of powdered coal is better understood, it is safe to predict that its sphere of usefulness will be greatly extended.

Pulverized Coal as an Industrial Fuel

The price of fuel for manufacturing purposes is an important factor in the cost of production, especially in the case of large consumers, such as smelters, iron and steel manufacturers, railways, steamships, etc.

The high price of coal, legislation curtailing the spark nuisance, the economy and ease of handling oil for steaming, are the chief reasons advanced by the railways, the mercantile marine, and the owners and managers of apartment houses for changing from coal to oil fuel for steaming and heating purposes. It is not proposed to question the accuracy of those statements, nor can they be conceded correct in many particulars. The industries which have made the change were no doubt satisfied before doing so that the step was a wise one. In any case the use of pulverized coal has been demonstrated beyond doubt to give better results than any other fuel for many manufacturing purposes. It is more economical than oil fuel, producer gas, or coal burned in the ordinary manner for many purposes; its milling, distribution and burning can be done at a low cost, it is simple to use and does not call for laborious work or any particular skill in operation; furthermore, if properly applied a great economy in fuel can be effected.



Engineers have known for many years the great waste of heat which takes place when coal is used direct for manufacturing purposes. Because of the wide application and long use of the steam engine, this is more noticeable in the production of steam than in many other uses. The work delivered by the ordinary steam plant of our time seldom exceeds 10 per cent. of the total energy of the coal consumed, and in many cases much less. The conversion of coal into "producer gas," and its application to industrial uses, was a great step forward. The heat returns from producer gas generated from a given amount of coal were several times greater than could be realized from burning the raw coal, and

*Paper read before the Vancouver Chamber of Mines.

where conditions are suitable for its application this gas is a highly economical fuel. In districts commanding a market for the residual products, producer gas is a source of cheap power, particularly if the capacity of the plant is large and adjacent to some large city or cities to which the surplus gas may be piped and sold. The great distances separating the centers of population of British Columbia do not lend themselves to the economical establishment of such plants beyond the cities of Vancouver and Victoria.

Ostensibly, because of the high price of coal, fuel oil has replaced it to a considerable extent for manufacturing purposes in this province. Fuel oil gave more heat volume for volume, reduced the labor in firing, and is supposed to prevent forest fires (long attributed to sparks from locomotives burning ordinary coal) along the routes of railways. Oil fuel has been extensively applied to industrial uses in the eastern United States, but the supply failed to keep pace with the expansion in consumption.

Improved methods of distillation reduced the quantity of residual fuel for manufacturing purposes, research work has shown that quite a number of the components of crude oil are far too valuable for such use, and the scarcity and uncertain supply caused engineers and manufacturers to cast about for a more permanent supply of cheap fuel. As on many previous occasions science solved the difficulty, surmounted it by the use of pulverized coal, and made a permanent and cheap supply of good fuel available to manufacturers for all time. Smoke in industrial cities has been a recognized nuisance for a long time, and has from time to time attracted considerable attention. Legislation to curtail it is in effect in several of the industrial centers of the United States, and is now being grappled with by the government of the city of Vancouver. Mr. Bird, chief smoke inspector of Chicago, where the smoke nuisance is much less than in Pittsburgh, estimates the loss due to wear and tear of clothing, house and building, cleaning, etc., as equivalent to $17,600,000 a year, or a per capita tax of $8 for that city. This estimate neglects entirely the injurious effect of smoke on the health of the people, and the direct loss of fuel energy.

HALF SECTIONAL VIEW OF A COAL PULVERIZER

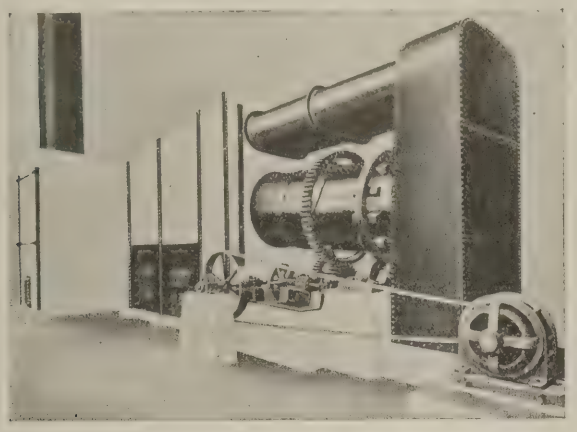
Smoke is the direct product of incomplete combustion and has been the bugbear of all large fuel consumers. For years their best efforts have been directed to train firemen to prevent it. So long as firing is done by hand, and smoke elimination calls for better attention on the part of the stoker, with the human element a variable factor, it is doubtful if any radical improvement can be expected.

The mechanical stoker promised an improvement and was a step in the right direction. But even here considerable difficulty is experienced in gaging an accurate air supply for the fuel, securing proper furnace construction, in the varying qualities of fuels at different localities and works, as well as from many other causes too comprehensive to enumerate in a brief paper of this kind. Pulverized coal, properly prepared and burned, promises a satisfactory remedy for the smoke nuisance, and when its merits are better understood by the public and its use becomes more widely extended bids fair to make the cities of the future smokeless.

To John V. Culliney, superintendent of the American Iron and Steel Co., is due the credit of being the originator of the first really successful system of burning pulverized coal as a fuel for metallurgical purposes. By perseverance, he worked out and perfected a fuel-controlling device that turned failure into success, and from a small beginning over a decade ago, the use of this fuel has extended to large proportions at the present time.

This company alone is now operating 77 furnaces with this fuel, is doing the work of puddling, busheling, rod heating, upsetting, etc., and consumes in its operations over 150 tons of coal per day.

Preparation, Application and Burning



The value of any fuel depends on the amount of its heat that can be converted into useful work. No fuel is a cure-all. Results from different coals vary according to the composition and traits inherent in each, and consequently this applies to coal in the pulverized state as well as that burned in the ordinary form.

Speaking generally, if a good supply of bituminous coal is available at reasonable cost, and the fuel consumption will warrant the installation of a coal handling, milling, distributing and burning equipment, the use of pulverized coal will effect a large saving. To obtain the best results, powdered coal must be dry and fine; and by "dry" is meant that it must not contain more than 1 per cent. of moisture. This has a double advantage; dry coal requires less power to pulverize, and better results are obtained in burning it.

By "fine" is meant that 93 to 95 per cent. should pass through a 100 mesh sieve, or 80 to 85 per cent. through a 200 mesh. In this state the particles are so finely divided that in a properly constructed burning apparatus each one is surrounded by the amount of air necessary for perfect combustion and the entire fuel energy of the coal is liberated instantly. It is obvious the finer the coal the faster it will burn, since coal in a finely divided state exposes a much greater surface to the action of the flame and air than lump coal. The volatile gases of the pulverized coal ignite instantly upon the entry of the fuel into the combustion chamber; the fixed carbon in suspension is consumed by the heat of the volatiles, and to the casual observer the flame resembles that of oil or gas. By the addition of more air or fuel the flame can be varied at the will of the operator, the control simply consisting of opening or closing the valves that regulate the supplies. The fire is under ab-

solute control at all times, and the entire combustible content of the coal is converted into heat.

Without going into details of specifications or costs, a general description of a plant necessary for the preparation and burning of powdered coal is approximately as follows: From the source of supply the coal

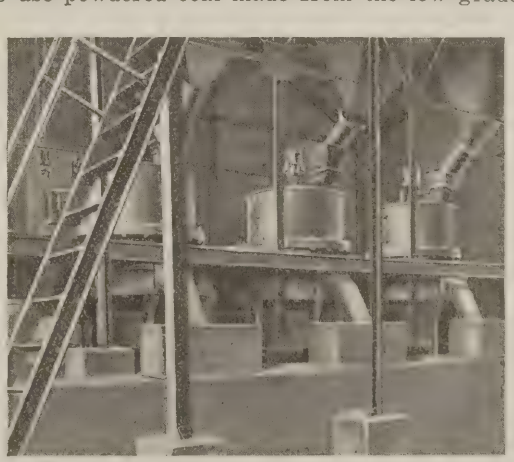
COAL DRYING KILN WITH DRIVING MOTOR

is delivered to a crusher and reduced to a suitable size for delivery to a pulverizer. In passing from the crusher to the pulverizer it is subjected to magnetic separation, to insure the removal of any tramp iron or steel it may contain. After passing over the separator, it is raised to a storage bin from which it is fed to the dryer and thence to a dried coal bin. From here it is led to the pulverizer. The finished article is elevated to a suitable bin or receptacle, from which it is distributed by a conveyor to individual hoppers at each furnace and thence fed to the burners. The complete operation is nearly automatic and under absolute control all the time.

The controller or device which regulates the feed to the burners is to the powdered coal furnace what the carburetor is to a gasoline engine. It must be flexible in adjustment, and since it determines the amount of fuel supplied to each burner it is attached to the bottom of the coal hopper at each furnace. It consists of two screws, the upper one propelling the coal forward to a certain point, at which it falls in a steady stream before an opening through which issues a jet of low pressure air, and by which it is carried to the burner. If the quantity delivered by the upper screw is greater than the air supply can carry, the excess falls into a cavity beneath in which another screw of a greater pitch works in an opposite direction. The overflow is thus returned to the hopper.

The construction of the whole apparatus makes it impossible to jam. It is practically foolproof and permits any portion of the falling stream of coal up to the capacity of the screw being used at the will of the operator, simply by turning on more or less air.

The quantity of air passing the controller is about one-seventh the amount required for complete combustion. The balance is of much lower pressure and enters the furnace at the burners. The controller screws are operated by chain drive, or connected direct to variable speed motors as conditions may require.



The current of controller air serves a double purpose. It not only forces the coal to the burner, but in picking it up gets intimately commingled with it, and both enter the furnace in a well-mixed cloud. This cloud is ignited immediately upon its entry into the combustion chamber, and meeting there the balance of air necessary for complete combustion bursts into a clean flame. The length of the flame can be changed by simply adjusting the burner to suit any desired purpose. The volatile content of the coal has also a material effect on the length and nature of the flame, but proper adjustment may be made therefor immediately. The use of this new fuel has been so simplified that operators soon become accustomed to it, and have no difficulty in regulating the furnaces to meet any necessary requirements.

For small furnaces, where a more or less uniform class of work is done, such as rod-heating, heating small forgings, in nut and spike furnaces, etc., the controller is so speeded as to give the maximum amount of fuel required for each heat, and is so arranged that the operator cannot exceed this amount. In large furnaces such as openhearth, continuous billet, reheating, etc., a variable change-speed device is employed, and is usually capable of a wide range of operations.

There are some cases where it is desirable or even necessary to maintain a constant degree of heat in the furnace, and variation would interfere with results. In others, such as puddling furnaces, etc., it is necessary to push the furnace at one period and slack off or hold the heat uniform at another. All these conditions can be satisfactorily accomplished in the control of a pulverized-coal fire.

The following extracts are from papers by H. R. Barnhurst, mechanical engineer, of the Fuller-Lehigh Pulverizing Co., read before the Engineers' Society of Pennsylvania, and the American Institute of Mining Engineers, at New York:

In 1912 the Missouri, Kansas & Texas Railroad Co. installed at the power house of its new shops at Parsons, Kan., eight 250-hp. O'Brien boilers of the Heine water-tube type, equipped to use natural gas or oil as fuel. Because of difficulties in getting supplies of gas or oil, it was decided to use powdered coal made from the low grade coals

VIEW IN A COAL-PULVERIZING PLANT

of the neighborhood instead. These coals ranged from 41 to 47 per cent. of fixed carbon, 26 to 32 per cent. volatile matter, and ash from 14 to 20 per cent. This equipment now in operation is giving better results than was obtained from gas or oil, and promises to be a pronounced success.

The cost of preparing pulverized coal depends to some extent on the quantity handled, the cost of dryer fuel, and the cost of power necessary for operating. The quantity of fuel required for drying depends on the amount of moisture

to be driven off; usually, 1 lb. of coal will evaporate 6 lb. of water in a well-constructed dryer.

The help necessary in using pulverized fuel is small. One man can operate a dryer of 6 or 8 tons hourly capacity, and one man can attend mills capable of grinding and delivering the same amount of coal to the furnace hoppers. The cost of repairs will not exceed 2c. per ton, and the power necessary for the complete operation is about 17 hp.-hr. per ton of product delivered.

Because with pulverized coal all the heating value of the fuel is available, considerable economies are manifest over other fuels. In continuous billet-heating furnaces a saving of 24 per cent. is made. In openhearth furnaces, 30 to 35 per cent. is saved as compared with the same furnaces fired with producer gas. In copper smelting a saving of 30 per cent. is effected, and for steaming, both locomotive and stationary boilers, a saving of from 20 to 30 per cent. is attained.

Regarding its effect on furnace brickwork and other linings, this is similar to what would arise from equal heat generated from coal or oil firing. Deterioration may be reduced to a minimum if short-flame firing and its corresponding low gas velocity is adopted. As with gas firing, the effect upon the brickwork is mostly confined to points where the path of the heated gases is diverted, as through vertical ports from horizontal passages.

This account would not be complete without speaking of the ash, most of which goes up the chimney or outlet for the products of combustion. In puddling and heating furnaces the small amount of ash left is carried off with the slag. It has given no trouble in the checker-work of openhearth furnaces. In steam-boiler firing the ash is best disposed of through a hopper bottom in the furnace.

There is no particular danger in the milling or use of pulverized coal if rational precautions are taken, and certainly the hazards of handling are not greater than those accompanying the use of oil or producer gas. Pulverized coal is subject to spontaneous combustion only in a degree similar to the coal from which it is manufactured. All well-constructed milling plants are made dust-tight, and open lights should be forbidden in such buildings. It may be safely stored in proper receptacles for five or six days without trouble; in practice, this has been done on several occasions. Storing for any appreciable time is not recommended, it is advisable to mill in about 10 hours all that is required for 24 hours. Much has yet to be learned about the best methods of milling, storage, handling and burning this new fuel, and like all other new things it remains for practical use to discover where improvements can be made.

Objections to Storage of Pulverized Coal

The use and manipulation of pulverized coal are now much better understood than in 1912 when Mr. Barnhurst contributed the foregoing paper.

The objections put forward against the storage of pulverized coal over long periods are that coal in a finely divided state, even when inclosed in air-tight receptacles, loses much of its occluded gases, and a considerable part of its value as a fuel. Further, difficulty may be experienced from caking due to excessive weight in the bins, and the material may not run freely.

Our remarks so far have been confined to the dry method of pulverizing and burning coal. However, the preparation and burning of coal in the powdered form is not confined to the dry method alone.

There is another machine on the market for doing this kind of work known as the "Aero pulverizer," so called because of the fact that an exhaust fan causes an induced current of air to circulate through the pulverizing machine. The coal is fed to the machine, powdered and delivered to the furnace without artificial drying.

I am informed this machine was first designed to meet the needs of a long flaming cheap fuel for cement making and that it has been applied later to various other industries and is reported to have proved highly successful. In construction it differs from the dry pulverizer, inasmuch as neither outside drying, milling nor storage is necessary, and the finished product is delivered direct to the furnace as made. The machine is compact and reduces to a minimum the floor space for installation. Its low price and large capacity are strong features to recommend it for many purposes in which the more massive equipment required for the dry method would not be suitable.

The makers report that this machine has been better tried out than any other form of pulverizer and that results are entirely satisfactory wherever it has been installed. It is offered in stock sizes with capacities varying from 600 lb. to 5000 lb. of pulverized coal per hour. All wearing parts can be duplicated from stock at any time. It is so compact that it may be installed on a locomotive tender, or adjacent to each furnace on steamships, and the fuel fed to the furnace as it is pulverized.

Pulverizers in Many Different Sizes

The smallest size occupies a space 5 ft. long, 2 ft. 6 in. wide and 2 ft. 6 in. high, and has a capacity of 600 lb. of pulverized coal per hour. The large size occupies a space 10 ft. long, 4 ft. wide by 5 ft. high, and has a capacity of 5000 lb. per hour. There are a number of intermediate sizes and capacities between the two quoted.

This machine may be set up either at the front of a furnace, on either side or above, and attended with little labor by the ordinary fireman. Neither dryers, elevators nor storage bins are necessary; the mechanism is dust-tight and self-contained, has few parts to get out of repair, and the principal wearing parts are easily accessible and may be quickly replaced from stock duplicates by any ordinary mechanic.

For manufacturing purposes in the eastern United States the use of pulverized coal has made remarkable strides in the last few years. Firms using it report that it is more efficient and economical than any other fuel they know of, and all are agreed that when it is better known by manufacturers and workmen it will have a wide industrial application.

This method of coal consumption opens a market for the immense lignite deposits of the prairie provinces, which have hitherto been considered of little commercial value, and bids fair to provide a cheap supply of good fuel for those prairie cities now depending on costly Pennsylvania coal. Apparently there is nothing to prevent it from being used for heating apartment and office buildings, at an equal or less cost than oil. It has the added advantage of removing to a great extent the present smoke nuisance. For this purpose the dry methods appear to be most adaptable. Coal could be pulverized at some suitable point in the city and distributed in a manner similar to that employed with the fuel oil now used. The capacity of the smallest plants of this type yet on the market are in excess of the needs of most apartment buildings in Vancouver, and hence a centralized pulverizing plant would be needed. The furnace changes necessary would be small and cost little, and the expense principally confined to the pur-

chase and installation of a small compressor plant to furnish an air supply.

The coal-mine operators of this coast should take up this matter seriously. They are likely to find it an efficient instrument to combat competition from foreign fuel oil, and might be well advised to install it for steaming at their works and for locomotive use on their branch railways. Large coal consumers are naturally shy of experimenting with a fuel they know little about. As a matter of business the mine owners should make the necessary tests at their works and show their customers the benefits to be derived from the application and use of pulverized fuel.

The majority of the coals of British Columbia are of a high volatile character and suitable for making a high-grade powdered fuel. Much has been heard in the last year or two of the great value that is likely to accrue to Canada from the work of a bureau of research, instituted by the Canadian Pacific Ry. at Montreal. If this bureau is as interested as its members would have us believe in the conservation of the resources of the country the fuel question on this road in British Columbia affords them ample chance to prove the worth of the bureau. Surely this is of equal importance and as worthy of attention as the solution of the waste straw problem of the prairies now engaging attention.

Further, take the anomalous case of the Grand Trunk Pacific Ry., a road built with the money of the people of Canada, traversing several coal fields on its route through British Columbia—proved steam coals of high quality—yet for some inexplicable reason using California fuel oil for motive fuel.

Three out of four of the public railways traversing British Columbia use oil as fuel. Even the Esquimalt & Nanaimo Ry., whose route passes through the principal coal fields of Vancouver Island, burns foreign oil for motive power. It is natural to ask if an abundant supply of coal is available and is as cheap as oil, why this preference for a foreign product?

To do justice to this subject the explanation would be so extended as to prolong this paper beyond reasonable limits. In short, it is in part due to the fact that the principal coal mines on the coast are controlled by a rival road, and it is too much to expect any party to encourage its competitor, except under exceptional circumstances. Furthermore, the new railways traverse sparsely populated districts for long distances, and although good coal is found at many points little market for it exists. As a consequence coal mining is not being done. If the new railways wished to use coal for steaming purposes they would be compelled to mine their own fuel. There are also several contributory causes, such as an inability of the new roads to finance coal-mining operations at this time; the fact that it is easier and more convenient to buy oil than mine coal to replace it, and many other considerations.

However, the day is at hand when the industries of this country must rely upon coal fuel. The oil supply becomes more uncertain each year. Modern methods of fractionation have shown that crude oil is too valuable to be used for ordinary fuel purposes. Even if available (unless the price is much lower than at present) it will be unable to compete commercially with coal, more particularly if this is used in the pulverized form.

Byproduct Coking

By M. Meredith
Liverpool, England

Since 1900, when coke ovens of the retort type were little in use in Great Britain, a revolution has taken place in the system of coking and large numbers of retort ovens with apparatus for the recovery of byproducts are now in existence. This number furthermore is being constantly added to. The war having stimulated the demand for hydrocarbon explosives, these are now commandeered by the government and the coking apparatus necessary for recovery of the explosives is under the control of the ministry of munitions.

Although the principle of the external heating of the retort oven as originally introduced by Evence Coppée remains the same, considerable modification in detail has been gradually introduced by various builders as the result of experience. The object of these modifications has been chiefly to increase the rapidity of the coking process by the application of more intense heat, and by the heating of the air for combustion. Convenience and economy in operation have also received much attention.

The recovery of byproducts has been greatly developed, and many experiments have been made with more or less success for achieving the "direct" recovery of sulphate of ammonia. One of the most important developments has been the utilization of the surplus gases in internal combustion engines and also in town illumination, metallurgical furnaces and for other manufacturing processes.

Legal Department

When Negligence of Employer Is Presumed—If a mining company's employee was injured through the coming off of a car wheel, negligence of the company in failing to discover and repair the defective condition causing the accident may be inferred from the fact that the wheel was considerably worn and was loose for some time before the accident. (Alabama Supreme Court, Ross vs. Sloss-Sheffield Co., 77 Southern Reporter, 686.)

Evidence in Mine Gas Explosion Case—In a suit to recover damages against a coal-mining company on account of death of a miner who was fatally burned in an explosion of gas in the company's mine, it was error for the trial judge to permit a witness, although experienced in mining operations, to give an opinion to the effect that he was satisfied from his examination that the deceased man knew how to use a safety lamp, to rebut plaintiff's claim that the company was negligent in entrusting a safety lamp to decedent. It was for the jury to determine from all the evidence in the case whether the circumstances justified so entrusting decedent with the lamp. Under the Alabama statute which requires that satisfactory evidence must be furnished a mine foreman of a miner's ability to use such a lamp, the foreman is not sole arbiter of the fact. The statute means such evidence as would reasonably satisfy an ordinarily prudent and careful foreman that the miner understood the proper use of such a lamp. But, in any suit wherein there is a dispute as to whether an injured man's own negligence contributed to the accident on account of which he sues, declarations made by himself just after the occurrence of the accident are admissible insofar as they constitute admissions of self-carelessness. (Alabama Supreme Court, Alverson vs. Little Cahaba Coal Co., 77 Southern Reporter, 547.)

Rules for Electric Wiring in Mines

THE West Virginia Engineering Co., of Charleston, W. Va., is promulgating the rules for electric wiring given below. Although it is difficult to lay down specific instructions in all instances, the rules here given cover the vast majority of cases and may well serve at least as a groundwork upon which, if necessary, more elaborate and detailed rules may be built up.

1. All power circuit mine wiring must be done with approved mine type insulators and pins, 20 ft. to 25 ft. apart where the roof is low, and where the roof is sufficiently high to permit it, 30 ft. to 35 ft. apart.

2. One wire only may be placed on an insulator, securely tied with at least five turns of No. 4 copper tie wire on each side of the insulator.

3. Where conditions are such as not to permit the hanging of wire on the roof, cross timbers not smaller than 3 x 4 in. must be used, placing them so as to bring all insulators as near as possible to one height.

4. The cold or negative wire must be put up and maintained with the same care as the positive, and in no instance thrown down along the entry or placed underneath the road or track. All wires when erected must be put up with care and pulled up snug and taut, so as to remove all kinks and slack. They must not be allowed to touch slate, coal or timber, but must be erected and maintained at a safe distance therefrom and not less than 10 in. apart. The practice of wedging insulators between wires or between wire and coal, etc., should not be followed.

5. Butt entries must be wired with the same care as face and main entries and provided with two S. P. switches of not less than 200 amp. capacity. No breakers or fuses will be permitted at these points.

6. Where face entry wires leave main line, switches should also be used.

7. Where entries advance beyond the limit of the machine cable, No. 4 copper wire should be used for a distance of about 600 ft. or the length of a longer roll of wire. This wire is to be replaced with wire of larger size as soon as the entry has advanced sufficiently to allow the use of a complete coil without cutting.

8. Under no conditions are live coils to remain hanging at the head of entries or at the ends of any wires, and a No. 4 wire must not be employed for a greater distance than 800 ft., but must be replaced promptly with wire of larger size.

9. No rooms or working places are to be wired.

10. Entries must not be wired beyond the last breakthrough.

11. Power circuits should not be permitted in return air courses.

12. The amount of wire in mines must be minimized as much as possible, and where circuits are no longer necessary the wire should be disconnected at once and removed as soon as possible.

13. The practice of allowing wiring to remain in old breakthroughs, crosscuts, etc., should not be permitted, and old tie wire, broken bonds, scrap wire, old cables and coils of wire must be gathered up and kept in an orderly manner under lock and key where it may not be accessible to everyone. All scrap wire, etc., must be disposed of promptly and not allowed to accumulate in quantity.

14. The terminal ends of all large wires must be securely anchored and thoroughly insulated with a turnbuckle and strain insulator. Dead ending on wood crosspieces or posts without the use of an insulator should not be permitted.

15. Whenever there is danger of a wire being touched, as for example where it crosses an entry, the roof should be trenched at least 10 in. deep and the wire securely placed on insulators. The trench should then be covered by 1-in. boards fastened to wooden pegs driven into the roof. The wires must not touch the board but must be thoroughly insulated and well separated from it.

16. The use of jumpers should not be permitted.

17. All wire joints 2/0 or larger must be made with brass sleeves thoroughly and neatly soldered. For smaller sizes use Dossart "A" or regular Western Union joints with no less than six turns on each and thoroughly soldered.

18. Where wires go through wooden or brick brattice work or other partitions, they must be thoroughly protected with porcelain tubes. The tubes, if in wood partitions, must be held in place with tape; if in brickwork, they must be cemented so that they cannot be moved.

19. Where partitions, brattices, etc., are built after wires have been erected, split tubes must be used to avoid the cutting of wires.

20. In wiring entries where a metallic circuit is used, care must be taken that the positive or hot wire is always placed next to the rib, the negative or cold wire being placed 10 in. on the outside of the hot wire.

21. The hanging of wires on nails, whether wire is insulated or not, should not be permitted, and wood cap pieces, etc., must not under any circumstances be used to keep wire away from the ribs.

Trolley Wire and Bonding

1. Trolley wire may be suspended inside the mine on hangers, lag screwed to cross timbers, or where the roof will permit, from expansion bolts fastened to the roof.

2. All new trolley will be of the standard grooved or figure 8 pattern; care must be taken that no kinks, sharp turns or dents from come-alongs are made in it.

3. The center of each hanger should be plumbed 7 in. outside the outer edge of the rail. Hangers should be placed about 20 ft. apart on straight entries in low coal and 35 ft. apart in high coal. Considerable latitude will have to be allowed, as no specific rule can be made for distance apart of hangers, but the above is a fair average when wire is erected and maintained properly. On curves the distance should be 8 ft. to 10 ft. between hangers.

4. Barn hangers are provided with four holes, while two holes diametrically opposite are sufficient. Use ½ x 2½-in. gimlet point lag screws, drilling holes for same with ⅜-in. twist drill. Do not use track spikes or nails for fastening hanger bodies to timbers.

5. Frogs should be placed 2½ ft. in advance of point of latch and held in horizontal position by properly placing hangers on line near frogs.

6. Frogs must be placed at each point where branches leave main trolley and when properly placed will not necessitate the holding of pole when passing over frog at ordinary speeds.

7. Automatic trolley switch and signal lights must be placed at all partings where mules will pass under the trolley. Automatic switches are not expected to sustain severe stresses and should be relieved of such by proper disposition of strain ears and hangers.

8. The ends of trolley wire must be securely anchored and thoroughly insulated with turnbuckle and strain insulator. A three-bolt galvanized clamp should be used for fastening the end of the wire when it is bent on itself through the strain insulator.

9. Care must be taken that the trolley wire clears the roof, so that the trolley wheel will not touch the roof at any time.

10. Where feeders are necessary they must be erected the same as main lines and tapped in at proper intervals by means of feeder ears. Hooking a jumper around an ordinary hanger should not be allowed.

11. At the end of the motor road where machine lines ground to rail or at the point where the rail circuit returns to the plant, it is well to use several bonded wires leading to return and to bond each individual wire into the rail in more than one hole, also to provide a cross bond at this point.

12. Bond both sides of track, using pin expanded or compressed terminal bonds.

13. Be careful to drill holes exact size, using nothing other than a twist drill.

14. Bonds must be placed on inside of rails and extended beyond the fishplates to such lengths as will allow removal of the fishplates without disturbing the bond.

15. Cross bond every fifth rail, making bond of sufficient length that it may be bent down below the top of the ties so as not to be interfered with.

16. Where rails are shipped with bond holes already drilled, ream out these holes $\frac{1}{32}$ in. and use a bond the proper size of terminal.

17. All switches must be cross bonded just back of the frog, all four rails being connected.

18. When drilling bond holes do not use oil as this acts as an insulator to a certain extent and does not allow the best contact.

19. The following length of bonds should be used for different weights of rails:

Weight of Rail, Lb.	Length of Splice Bar, In.	Length of Bond, In.
30 to 35	16½	22
40 to 45	20	26
50-55-60	24	30

Cross bonds should be 6 in. longer than the track gage.

Mine Lighting

1. Where it is necessary to wire partings, slopes, curves, pump houses, etc., use receptacle and No. 12 triple braid, weatherproof wire and No. 4 porcelain knobs.

2. No rosettes, snap switches or ordinary sockets should be used in the interior of the mine.

3. No switches or fuses will be required. Where a large number of lights are used fuses and switches can be used to advantage.

4. The practice of hooking ends of light wires over power circuits should be discontinued and connections made in such a manner that vibration of the line will not form arcs, burning the large wire. Screw connections must be used.

5. Where it is necessary to turn lights on and off frequently in interior of mine, knife switches should be used.

Substitutes for Coal

BY FRANK HALL
Harrisburg, Penn.

THE incalculable value of coal as the source of power in the industrial world, and the source of comfort in domestic life, gives rise periodically to the query, How long will the coal supply last? and the natural corollary, Can any substitute be found when the coal supply is exhausted? The answer to both questions is indeterminate and unsatisfactory. The vast unmined deposits of coal, however, give assurance of a plentiful supply of fuel for at least 100 years to come, even with a constantly growing demand.

In the United States, including Alaska, the deposits are placed at 4,231,352,000,000 tons, or half of the total of the world. A great part of the deposits, however, lie below a practical mining depth. In Pennsylvania, the unmined anthracite deposits are by one authority estimated at 10,638,902,809 tons, half of which may be available, or 5,319,415,404 tons. Another computation shows that 6,512,167,703 tons are available. Estimating the annual production at 70,000,000 tons, the duration of this industry in one case would be about 73 and in the other about 93 years.

In the bituminous region, according to the latest estimate of the Federal Government, there still remain about 109,000,000,000 tons unmined, or an amount sufficient to continue the present rate of production for 500 years. This estimate, however, is deemed extravagant by the best informed mining men. The 26 counties of Pennsylvania now being exploited comprise practically all of the coal-bearing measures of the region, and from some of them the greater part of the coal has already been extracted. It is probably nearer the mark to say that another hundred years at the present rate of production will no doubt bring to the point of exhaustion the rapidly diminishing deposits of the bituminous region of the state.

If the estimates given above can be accepted as reliable, the tremendous quantity of reserve coal at the disposal of future generations should effectually dispel for many years to come any apprehension as to the possibility of distress resulting from a lack of fuel. It must be borne in mind, however, that the most trustworthy estimates are after all merely estimates, and the actual deposits when exploited may prove disappointing in volume.

The extended and rapid increase in consumption must also be considered. Almost incredible has been the growth of the coal industry in recent years. One authority declares that if the acceleration continues, the coal supply in the United States will probably not last 100 years. It may be accepted, however, as highly improbable that the increase will continue indefinitely at the same ratio in the future as in the past.

After considering the subject from various angles and comparing the many estimates of the coal deposits still unmined and the probable consumption in the future, it would seem that at least for the next 200 years the coal supply in the United States will be ample for the needs of the population.

These conditions make imperative the ultimate finding of a substitute for coal, but what it will be, its nature or character, no one can predict. There are no natural substitutes for coal to be found in Pennsylvania, but in some of the Northeastern states, as well as those near the Great Lakes and also along the South Atlantic coast, there are large deposits of partially decomposed vegetable matter commonly designated as peat, which has a fuel value per pound equal to about one-half of the value of the higher grade coals and nearly equal to the lower grade coals or lignites.

This material can, with proper treatment, be made to serve as fuel, but the process of preparation is rather complicated and expensive. The product when ready for the market is really a manufactured article. Peat has been used for centuries in Europe as a domestic fuel, but it has only been within the past decade that it has reached any importance as a fuel for power plants in competition with coal and lignite.

The manufactured substitutes for coal in this country, so far, are briquets or boulets made from the refuse of anthracite or mixtures of anthracite and bituminous, bituminous slack or sub-bituminous or lignite. Some of these manufactured products are gradually winning favor with the public and may in time, when more perfectly made, prove commercially successful and be a

real factor in conserving the coal deposits. With the increasing demand for fuel, especially of the better class for domestic use, in connection with the increasing cost of labor both in the mines and in transportation, the growth of the briquet industry will no doubt be rapid and substantial.

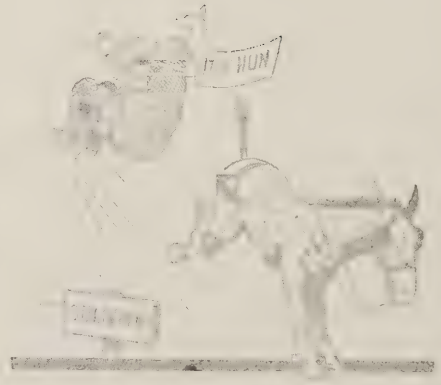
We have not as yet reached the time, however, when the briqueting of all fuels will prove profitable. It is almost out of the question to briquet good coking coals for either industrial or domestic purposes, for the reason that the briqueting of these coals does not change their nature. If ordinary binder is used, it may increase their smoke-producing qualities during combustion, so that fuels of this nature can be better treated by carbonization or coking, especially if the byproducts are saved.

The best field for this industry is in the briqueting of fuels possessing poor or no coking qualities—the slack and fine coal at the mines and shipping centers, which is practically useless or of little value for any other purpose. Of this large quantities are produced in many parts of the country and are either left at the mines or sold at a price considerably below the cost of production. This class of fuel can be converted, if smokeless in its natural state, into an entirely smokeless and odorless product by the use of proper binders. Even fuels containing a considerable percentage of volatile matter, which are more or less objectionable for domestic use in their natural state, can be converted into briquets that will be superior to the prepared and screened sizes of the natural product, from the dust or breakage of which they are made. The latest product now on the market to bid for favor as a coal substitute is what is called carbocoal, a fuel produced from bituminous coal by a method of distillation at relatively low temperatures in which there is simultaneously obtained a sufficient quantity of valuable byproducts to largely offset the cost of converting the raw coal into a refined, smokeless product which will substitute satisfactorily for anthracite. Carbocoal is claimed to be a near approach to a perfect fuel. It is said to be smokeless, ignites with comparative ease, burns freely and completely under all draft conditions and is dense, dustless, clean and uniform in size and quality. It remains to be seen what place this highly eulogized fuel will take in comparison with bituminous and anthracite.

Substitutes for coal in the way of briquets and boulets, no matter how satisfactory they may be as a domestic or power fuel, are in the last analysis merely substitutions of coal in one form for coal in another, the basis of all the manufactured fuels of this type thus far placed on the market being coal. Hence they serve the purpose only of conserving in a small degree the raw grades of fuel. If the coal supply should become exhausted, the many forms of substitutes now clamoring for public approval would also cease to exist.

What is wanted, and what the scientific thought of the world must devise, is a genuine substitute for coal, one that can be manufactured independent of coal as a chief ingredient. Unless this is done, the world will some day face a real and permanent heat famine, the horrors of which can scarcely be imagined.

DRAFTED!



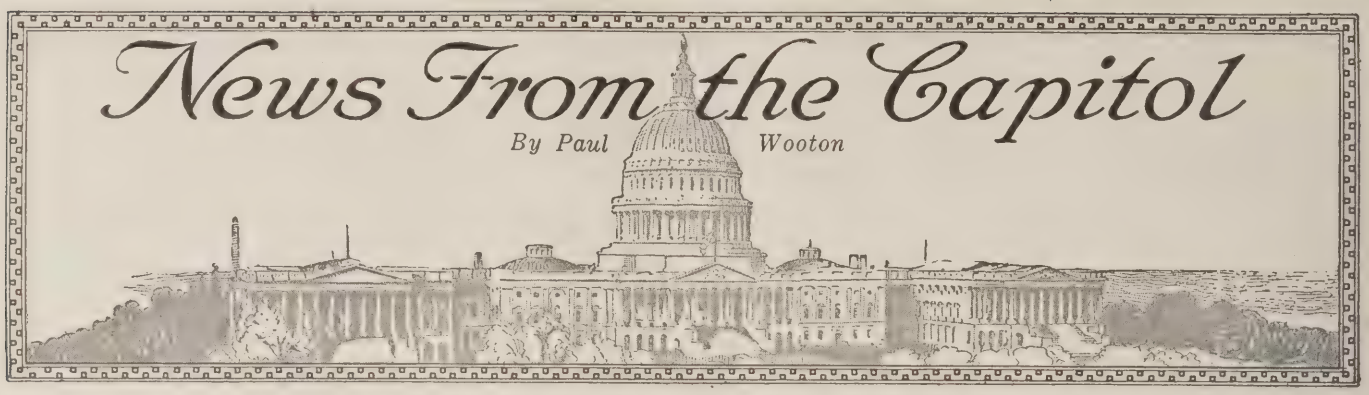
By Rufus T. Strohm

Goodbye, old mule!
It's mighty tough to see you go,
But Uncle Sam—who ought to know—
Has found he needs you over there
To help the nation do its share.
You'll probably be hauling guns
To blow the brain-pans off the Huns.
Well, show them that you're not a fool—
Goodbye, old mule!

Goodbye, Old Mule

Goodbye, old top!
I used to rave and swear at you
Until the very air was blue,
And every second word I spoke
Was wreathed in clouds of sulphur smoke.
I reckon, after you are gone,
And I've no one to practice on,
My cussing days will have to stop.
Goodbye, old top!

Knock a Hundred Boches Out



Goodbye, old pal!
You needn't have a pang of fear
That Fritz will finish your career.
No missiles made of steel or lead
Can ever dent your thick old head.
If it could yield to any blow,
Why, I'd have cracked it long ago.
You'll always have a strong morale.
Goodbye, old pal!

Goodbye, old scout!
I've put the quartermaster hep
That you've a fierce, unlovely rep
For impish tricks of every style
That make a mine mule's life worth while.
So, if they mix you in the fray,
Put both those frisky heels in play
And knock a hundred boches out.
Goodbye, old scout!

Every Pound of Slate Keeps a Pound of Coal Out of the Market

The Railroad Administration can only supply us with a few cars. Let us do our best to keep slate from taking up the space that should be occupied by coal. Otherwise, this winter Uncle Sam will have only a small poke of coal for each person, and all will go cold.

Weekly Production Statistics

Production of bituminous coal during the week ended May 18 bids fair to pass the 12,000,000-ton mark. Telegraphic advices to the Fuel Administration indicate that that week will surpass the production performance of any week during the twelve months preceding.

Production increased during the week ended May 11, when 11,806,000 tons were mined. This is a slightly better showing than was made during the record week ended April 27. Beehive coke production during the week ended May 11 was 655,000 tons, which shows a slight increase over production during the week preceding. Byproduct coke production was 536,544 tons. Production was cut somewhat by a labor shortage at the Bethlehem steel plant at Northampton and at the Cambria steel plant at Johnstown.

Anthracite forwardings showed a decrease of more than 5 per cent. over the week preceding. During the week ended May 11 they were 38,314 cars.

During the week ended May 4, the coal mines of the United States were operated at 75.6 per cent. of their full-time capacity. The loss was distributed as follows: Car shortage, 13.1 per cent.; labor shortage and strike, 5.4 per cent.; mine disability, 2.9 per cent.; no market, 0.9 per cent.; other causes, 2.1 per cent.

The figures given above are those compiled by C. E. Lesher, the geologist in charge of coal statistics for the United States Geological Survey.

Fuel Administration Takes Over Statistical Bureaus Dropped by McAdoo

To continue the collection of absolutely essential figures, the Fuel Administration, at an expense of $3000 per month, has been forced to continue the Ohio Bureau of Coal Statistics and the statistical end of the Illinois-Indiana Coal Traffic Bureau and the St. Louis Coal Traffic Bureau. The Railroad Administration recently cut off the appropriation for the maintenance of statistical bureaus. It is probable that the Fuel Administration will have to reëstablish other of these bureaus. The action of the Railroad Administration is being criticized by some from the fact that no actual saving will be made as the Government will have to pay for the collection of these figures. It will have the effect, of course, of making a better financial showing for the railroads.

The bureau which has been charged with the collection of statistics regarding coal moving to tidewater has been taken over by the Tidewater Coal Exchange.

New Prices for Arkansas Anthracite

Prices for Arkansas anthracite at the Bernice mines at Russellville and at the Spadra mines at Spadra have been announced by the Fuel Administration as follows:

Bernice Mines—Grate, $7.75; egg, $8; stove, $8.75; No. 4 nut, $8.75; pea, $6.75; buckwheat, $2.85; slack, $2.50.

Spadra Mines—Grate, $7.25; egg, $7.25; No. 4 nut, $7.75; pea, $5.25; slack, $2.50.

The prices are subject to a reduction of 75c. during May; 60c. in June; 45c. in July; 30c. in August and 15c. in September.

May Investigate Shortage of Coal Cars

An investigation of the shortage of coal cars probably will be made by the Senate Committee on Interstate Commerce. The Fuel Administration has been asked to furnish the committee with such data as it may have which have a bearing on car shortage. It is not the intention of the Senate committee to open up an extended investigation. It hopes to get at the high points of the situation and take prompt action in an effort to better conditions.

War Industries Get Good Coke Supply

War industries are better supplied with coke at present than at any time since last October. This assertion was made by Dr. Garfield in a letter to coke operators thanking them for their coöperation in increasing the movement of coke to furnaces and foundries. An extract from the letter is as follows:

It is not enough merely to maintain the present movement of coke. We must work still harder to take care of the constantly increasing demands and to establish conditions which will enable us to avoid in the future any slowing down of war industries.

We all recognize that the most serious difficulty has been lack of transportation facilities. There has been possibly more disposition on the part of some to find fault with the railroads and with railroad men than to coöperate with them in their efforts to remedy conditions. Permanent improvement may be brought about by coöperation, not by fault finding.

There have been many serious wastes of transportation facilities which, if eliminated, would make it possible to increase materially the movement of coke. Much has been done along these lines, but there is still great room for improvement. Unnecessarily long hauls should be eliminated. Coke operators should endeavor to dispose of their coke in the district to which such coke can be most readily moved. Cross hauls should be avoided where possible.

To Circumvent "Commercial Bribery"

In order to reach what the Federal Trade Commission calls "commercial bribery," Representative Sims, chairman of the Interstate and Foreign Commerce Committee of the House of Representatives, has introduced a bill which provides for a fine of not more than $2000 and imprisonment for not more than two years for any "person, firm or corporation engaged in interstate or foreign commerce or in any competition with other persons thus engaged to, personally, through an agent, attorney, servant or employee, or by the use of the mails or otherwise, give, offer, promise or loan to any such employee or the employee of a customer or prospective customer, any money or other thing of value for himself."

Getting Ready for "Coal Week"

Every effort is being made by the Fuel Administration to make the week beginning June 3 one of notable accomplishments in the way of securing orders for coal. In view of the important advantage to producers and dealers, if they have accurate knowledge of requirements, Fuel Administration officials feel that this is an important step in relieving next winter's situation. It is expected that state and municipal authorities will coöperate actively in the drive which will continue throughout the week. Women's clubs will coöperate and will be in charge of a house-to-house canvass. Four-minute men will appear in theaters and picture shows. The drive has as its object not only the securing of orders from the domestic consumers, but from all industries as well.

Brief Washington Notes

Virginia operators have protested to the Interstate Commerce Commission against the granting of the request of the Chesapeake & Ohio R.R. to increase coal rates.

Malcolm G. Chance, of Providence, R. I., has been appointed Fuel Administrator for Rhode Island. He succeeds George H. Holmes, who was forced to resign by the pressure of personal business.

Awaiting such time as the Director General of Railroads may find it possible to go personally into the matter, the railroad fuel situation, during the last week, remained entirely without change.

Provision probably will be made in the near future to insure larger movement of coal to North and South Carolina. The operation of the zone system in providing large quantities of fuel to tidewater ports has absorbed a considerable portion of the supply which would normally have moved into the Carolinas.

Government coal en route to an army post can not be diverted by state fuel administrators, according to an opinion of the Judge Advocate General of the Army. Such officials, he says, have no jurisdiction with respect to such property and railroads should disregard such orders.

Dr. Garfield's efforts to persuade A. H. Wiggin to continue as state fuel inspector for New York have been unsuccessful, and Mr. Wiggin's resignation has been accepted. He will retain his place, however, as chairman of the Fuel Administration's advisory board for the State of New York.

The Fiend's Soliloquy

By George M. Lantz
New Straightsville, Ohio

□

I AM THE PRINCE OF DEVILS, one of the Great Powers of the World.

Kings, judges, statesmen, warriors are at my command. Yea, there be ministers, teachers, doctors and even editors who dare not oppose me.

But among these I work only for pastime; my real mission is to enslave the producers of the world's necessities—to pervert the men who till the fields, who build bridges, who tunnel below the surface of the earth.

Where strong men, pioneers, are needed, there I go; I beckon for the saloon, the gambling den, the brothel, and retard the establishment of the church, the school and the home.

I sow poverty, insanity and disease and reap broken bodies, vacant minds and deformed babies.

I poison the brains of my victims, steal their strength, blunt their perceptions and then send them reeling into the mine or the factory. There is a slight miscalculation, a fall of roof, a misstep, and they are mine.

Men gather about the mangled remains and speak in awed whispers about unavoidable accidents and acts of God.

The Prince of Darkness Laughs!

An Act of God Indeed!

I promise men that which is not within my gift—wealth, power, courage, beauty. I introduce men to crime and immorality, and when they have been disillusioned I promise forgetfulness.

I lead men to the Chasm of Destruction, and when they have drained the dregs of misery and pain, with my foot I push the miserable fools across the brink.

I destroy all that is noble in men. All that they might become, all their possible achievements, I hang as trophies at my belt. Their savings, their homes, their families, their souls are offered up as sacrifices before me.

I direct those who prey upon their daughters; I steal the milk from their doorsteps; I strangle Hope in the breasts of wives and mothers, and in its stead I implant Anguish and Despair; children shudder at my approach. In my moments of calm I tremble at my own iniquity. Some day I will be banished from the earth; the beasts that I have created will become men again. In that day the most exalted throne in Hell will be my seat, for my followers will outnumber all others.

I Am Alcohol

EDITORIALS

Suppress or Reform Alien Papers?

THERE are lots of papers published in this country in the languages used almost exclusively by our enemies. Many of them are admirable exponents of real American principles. But, whether they are good or bad or merely indifferent, we do ill to suppress a single one of them. But this we may do with profit—we may modify their policy to accord with the national purpose.

If their editors prove recalcitrant we can put others in their places who are more to our liking. The man who reads a paper in an enemy language should not be permitted to absorb from it enemy-alien Kultur, certainly not during the war. We should not interfere with the freedom of our loyal press, but the right to be fed with a foreign Kultur in a foreign language during a war which is trying our national existence may appropriately be denied.

But we may go further even than just suggested. We can require those editors we retain to publish articles and editorials written by the Government laying down the national viewpoint, not particularly excoriating the enemy, but placing the facts before the readers of these papers. We can urge in those journals the need that all foreigners learn the language of this country to take the place of the enemy tongue.

And it does not follow that the papers will not be read. We fume cloudily about the enemy aliens, but for the most part they know that they ought to be with us, and really would be with us, if they could only gently root out their preference and predilections for their fatherland.

It is no small matter this regeneration, but careful propaganda in the alien tongue would eventually do the work and do it better than even our national journals could perform it if the enemy alien could read them, for during the heat of a war our native press naturally does not spare the feelings of those with whom we are contending. Of course, some would refuse to read the enemy-alien press after it had been thus renovated, but they would certainly not read our papers if we suppressed theirs, and when we suppress the enemy-alien newspapers we prevent the kindly and the unfriendly enemy alien alike from reading about the war, and we lose the opportunity of inculcating in the friendly enemy alien the spirit of Americanism.

Open an English School for Foreigners

IT HAS been the custom to inveigh against the foreigner because he uses the language of his native land and because he foregathers only with those of his own race and language. But he is not wholly to blame. How can he learn English with the few facilities that are offered him in most towns and villages? There is no one to teach him English. How can he associate with others when he has not had a chance to learn the language that they speak?

A large movement is being initiated to induce the foreigner to learn to speak and read English. It will utterly fail unless the opportunities for instruction are offered. There is, and of this we may be proud, no rooted objection to the English language, such as exists against the German language in Poland. The people who come here are no more prejudiced against English than the Welsh people were prejudiced against it; and we know that Welsh has almost entirely died out, though no one wished it so unkind a fate. The immigrant wants to learn our tongue. He feels like a deaf-and-dumb man until he does, for he is disadvantaged in all his operations till he can talk to those with whom he has to work. It is only a small percentage who use their "No forestay" for purposes of guile.

The foreigners, both men and women, are willing to go to school and learn English. The language of this country, fortunately, has not been made hateful to them by unfair treatment and jealous discrimination. There are countries where years of suspicion and traditional hatreds have made all attempts to introduce a new language hateful.

In such cases an organized opposition exists to the introduction of the language of the state. We may gratefully declare that it is not so here, and if we will give the foreigner half a chance he will do his best to rattle off English with the rest of us, at his work, on the street and in his home.

That there is no objection to the use of the English language is shown by the readiness with which the sons of immigrants accept it. Only on the farms will you find an immigrant's son who can speak his father's language with facility. When the boys mingle morning, noon and night with young folk no other language than English can they roll glibly off their tongues.

A school for foreigners is a wonderful investment for the operator. The men working for him will always be able to understand the manager and the foreman. There will be less dissatisfaction and lost motion. Americanized men can be put in good houses with the assurance that the homes will not be spoiled. When notices are posted the Americanized foreigners will be able to read them. They will do it for practice in the language if for no other purpose.

With training in English, accidents will be less numerous; the labor turnover will be reduced; strikes will be less frequent. What is more, there will be less need for strikes. The worst of all these troubles, the longest and most destructive, are those caused by mine workers who cannot be argued with and so cannot see any point of view but that of the agitator of their own race who happens to have their ear. At any mine the best foreigner of all those who come from a country where English is not spoken is apt to be the one who can speak English best. Few patriotic duties are clearer than this: To put plans in operation at once to establish schools for teaching English in every mine village.

Alaska Is Still Hermetically Sealed

NO ONE expected that the spoon-feeding methods of the United States Government would ever develop a large and thriving coal industry in Alaska. Men will go to the remotest portions of the earth to make a fortune, as the history of gold mining well shows. But granted that it takes more capital, attention and risk to make a small profit in Alaska than, for example, in Illinois, we shall unquestionably find the operator going to Illinois and not to Alaska. He will seek a field where conditions are not so rigorous, where so many strings are not tied to his activities and where there are not so many indeterminate factors to meet.

The Government has built a railroad from Anchorage, a tide-water port, to the Matanuska fields. It has opened the coal fields to the public in a carefully regulated degree. Coal has been arriving at Anchorage, but the price is discouraging. Instead of that price being $5 or $6 per ton, it has stood around $11 at the point of loading, before any shipping and unloading charges have been added. There are large deposits of coal in the Matanuska field, but private capital is not content to risk itself under the leasing provisions laid down by the Federal Government. For this reason the great field is being developed but sparingly, and Alaska is still importing British Columbia coal, though that province of the great Dominion has dire need for all it produces. There is every indication that it will soon cease exporting coal to the north. Thus there will soon be a great need for coal in Alaska, despite the fact that the territory's coal resources are greater than those of the State of Pennsylvania.

Coal at $11 per ton at Anchorage cannot be delivered at Seward, Valdez or Cordova, the towns nearest the coal fields, at a price within $2 or $3 per ton of the present price of imported coal. Therefore, unless some vital changes are made in the law under which these fields are being developed, and unless there are some inducements offered to capital to develop these fields upon a commercial basis, with a reasonable maximum price fixed for the product, the expenditure of $35,000,000 for the Government railroad is practically wasted, so far as providing fuel to the territory and the Pacific Coast is concerned. Yet the coal is badly needed there at this time.

If the Government desires to cheapen fuel in the territory and produce tonnage for its railroad, it should take down the bars and make it possible for private enterprise to develop the fields. Cheaper fuel is needed for the comfort and convenience of the people of Alaska, for furnishing the steam used in the mining of frozen ground, for the general development of Alaska and for industrial purposes all along the Pacific coast.

The urgency of these many needs make changes in the leasing law imperative. The present laws are not liberal enough; they do not permit a man to purchase the coal land, nor provide area enough to interest a rich man in opening a mine. The rental is too high for the poor man in view of the risk of the venture. There is greater risk in Alaska than in probably any other coal field. All things considered, the restrictions are such that the requisite capital cannot be secured to make the heavy expenditures found necessary in the development of these far northern coal-mine properties.

Who Are Free in the Land of the Free?

FOR GOOD and sufficient reasons, the mine worker in most fields is fined if he will not, on demand, sell his labor to the operator at the specified rate. In many states he is even jailed if he will not sell his labor to anyone. But these are war times, and such provisions are excellent.

For good and sufficient reasons, the operator in most fields is fined if he will not buy the mine workers' labor at the specified rate. It is well understood that if, for insufficient reason, he refuses to operate his mine, it is quite apt to be taken from him. These are war times, and no one can complain.

Who, then, is free in the land of the free? Why, the Railroad Administration. It has been refusing to buy the product of the operator and miner unless it can get its own terms. Despite the fact that the Government has named a fair price, the Railroad Administration regards itself as empowered to buy or to refrain from buying as it pleases. In the winter, when it needs coal, it can compel a sale; in the summer, when it is not in immediate need of coal, it can delay purchasing it for the winter. That is a wonderfully advantageous position to occupy, and the Railroad Administration is making the most of it.

Beside the Railroad Administration there are the free manufacturers of nonessentials and the free purchasers of the same. They buy and sell nonessential products at their pleasure, but they are coming gradually within the net; they are much less free than they were. As far as coal is concerned, the manufacturers of nonessentials are, beyond cavil, the most ardent of purchasers. They cannot commandeer coal and they tremble for fear that later on they may not be allowed to buy it at all. So they come readily into the market, are anxious to store coal, and would even buy railroad cars in which to haul it if the possession of cars would insure them a coal supply.

The Railroad Administration alone is indifferent. When, by the Administration's refusal to buy, a mine worker is laid idle, shall we fine it a dollar a day, payable to the Red Cross? Some such course would seem quite logical and advantageous, even though the public would have to meet the burden; for the Railroad Administration does not like unnecessary expenses because they cause it to make a bad showing. As it is not generous to the Red Cross, like some of our "soulless" corporations, a fine levied on it for the benefit of the Red Cross would rectify that matter and, furthermore, would put it on the same level in the conduct of its operations as the mine worker and operator, who are required to pay the Red Cross a dollar as often as they, in a moment of spleen, refuse to shoulder their reciprocal burdens and so fail to perform their whole duty in this national emergency.

We do not like to speak so plainly about the Railroad Administration's derelictions. We are sure its purposes are as excellent as that of any other organization. But we would like it for a while to look at the field of its activities from another hill and see its responsibilities with the light at a different angle. The interest of the railroads is not inimical to that of the public, and the public's interest is clearly not to be found in any delay in the buying of the coal for the coming winter.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The anthracite mine workers seem to be losing the high sense of obligation that has impelled them hitherto to work unremittingly and to "shell out" generously in the Liberty Bond campaign. The specter of the winter's shortage of anthracite ceases to haunt them as it should. Let them never for one moment forget that the long lines of waiting women and shivering children will form again if they relax their efforts.

A strike of 700 men and boys at the Maxwell No. 20 colliery of the Lehigh and Wilkes-Barre Coal Co. at Ashley, Penn., caused a complete shut-down of the works. The union called a meeting on May 16 and there was a tumultuous session, the officials of the union vigorously condemning the strike. The men eventually voted to return to work May 17 and to let their grievance be settled by the regular grievance committee.

The quarrel between the men and the company relates to an interpretation of the contract regarding yardage. If they are right in their contention that a larger allowance is due them, they can get the difference for the past as well as for the future from the commission appointed to adjudicate such grievances.

A button strike occurred at No. 5 colliery of the Delaware and Hudson Co., at Larksville, just outside Wilkes-Barre, Penn., on May 17. The trouble was caused by several men objecting to the payment of 50c. instead of 25c. a month to the union. It shows how strong the support of the union is in Luzerne County that the action of these men resulted in a strike. In some parts of the southern anthracite field whole unions are opposed to the change in dues, whereas in this colliery in the northern field a large majority is ready to resent by a strike any attempt to avoid payment of the higher poll tax. The strike laid idle 1200 employees and entailed a loss to the market of at least 900 cars. It is unnecessary to again condemn these button strikes as violative of contracts and as a restraining hand laid on the war activities of the nation.

In the rest of the country the news largely relates to Red Cross activity. The mine worker is being slowly educated to saving, while giving is an atmosphere in which he has long lived. The Red Cross consequently has a marvelous appeal to him, as a special article on this subject appearing in this issue will fully attest.

At the time this review is written the strike in the Huntingdon and Broad Top region is still continuing. It must be conceded that though the coal of that region is a high grade low volatile fuel the field is not an important factor in the coal industry. Consequently the fire of discontent will probably be allowed to burn itself out. The union is not backing the mine workers, for they are violating their contract. The Fuel Administration, it need not be said, is not favorable to the strike method of settling grievances.

No one is worrying about the situation. The cars which should go to the Huntingdon and Broad Top region will afford a pleasing addition to the scant supply of cars elsewhere. Profits are not high in the Broad Top field, and as a result operators will be content to have their mines remain idle. On the whole the only unsatisfied people will be the idle miners. Left alone and unnoticed in their quiet hill country they will begin to realize that after all the lack of their tonnage will not bring the country to their feet.

If the nation never heard of the miners of that region any more, the war would be just as effectively waged against Germany, and some men now idle would be making a better wage than they are today, and out of their plenitude doubtless they would be managing to save many dollars for Liberty Bonds and the Red Cross.

Cost-Plus Factories Filch Miners

Now that the dissatisfaction about the wage scale is removed the mine workers of Alabama are expected to work more regularly. The increase became effective May 15. The situation is nevertheless far from encouraging. An increase of wage may well make for contentment, a contentment such as makes some men, at least for a time, work harder, but also of a kind that makes some men content to work only a few hours where they worked a full day before.

James Bowron, president of the Gulf States Co., in an open letter, explains why Alabama producers cannot provide more iron and steel, but much of what he says about the iron industry of Alabama would not be any less apt if applied to the coal industry of the same state and region, and much of his statement applies specifically to the mining conditions at coal-producing plants.

"We are not in a position today to take any action toward an increased output. We could furnish the money for it, the good will and the executive ability, but there our power ends.

"We need an adequate supply of raw material and a conservation of our men. Raw material of every description is scarce in this district and what is produced is of an inferior quality. Many miners, both in ore and coal mines, are openly indifferent to the production of clean ore and coal. The volume of slate and dirt which goes through the coke ovens and the blast furnaces of the district makes necessary the use of additional limestone to flux the mix and additional coke to fuse it. In this manner the impurities in the coal and ore decrease the production of pig iron and increase the output of slag.

"On account of their high wages, many of the miners do not care for continuous work and many others, of course, have accepted the call of their country and have gone into military service. Men are scarce and in some cases the efficiency of those remaining is reduced.

"In addition to this, the pirating of labor seriously interferes with industry. There is hardly an industrial operation in this district that is not daily attacked by labor agents who try to take the men away to other places. The contractors, particularly the DuPont people, are building nitrate or powder plants for the Government on the cost-plus system and are offering any wages that may be necessary to induce the men to leave their present employments, and I submit that this system should be sternly controlled by the Government, as every man taken from one job to another at the expense of the Government is adding to costs at both ends and on the whole decreasing the efficiency of the nation's work."

Colorado Plan for West Virginia

To secure the fullest coöperation between operators and miners, and to remove all possible causes of friction, coal operators of central and northern West Virginia attended a meeting held at Fairmont, May 15, at the offices of the Federal Fuel Administrator for West Virginia. They, then and there, agreed to adopt what is known as the Colorado Industrial Plan of 1916 and this the miners will doubtless readily indorse. Each individual mining plant, under the plan, is to permit its employees to form an organization which will appoint a committee to meet with representatives of the company whenever any grievance is in controversy. Should such committees fail to reach an agreement the matter in controversy would then be referred to a central umpire.

About 69 different operations were represented at the meeting, the large attendance being due to the importance,

to the region in the northern part of the state, hitherto unorganized, of the new policy, the initiative in its adoption being taken by the Consolidation Coal Co. It is said that fully 95 per cent. of the tonnage of the Fairmont region was represented at the meeting.

Among the companies represented were the Consolidation Coal Co., the Hutchinson Coal Co., the Federal Coal and Coke Co., the Elkins Coal and Coke Co., the Clark, the Hite, the Jones and the Tom Arnette interests. The operators along the Coal & Coke Ry. and the Grafton & Belington division of the Baltimore & Ohio R. R. were also represented.

While many of the operators were not markedly enthusiastic regarding the plan which the Consolidation Coal Co. is to put into effect, yet nevertheless all the companies agreed to coöperate, the plan being finally approved by the Central West Virginia Operators' Association which recommended that individual operators adopt it.

Following the action taken by the operators, the employees of the mines in the Fairmont district are holding meetings and electing committees as provided under the plan of agreement.

Enthusiastic Liberty Bond Sellers

From Logan County, West Virginia, the information comes that the 175 employees of the Gay Coal Co. purchased on Saturday, May 11, between four and six o'clock, $12,000 worth of bonds, about $68 per employee. One man, Shade Nelson, the stable boss at the mine, who made good money and was in comfortable circumstances refused, it is said, to buy a bond. Every other man and many women and children had their names on the honor roll. When on Monday Nelson was found to have persisted in his refusal to buy a bond, a committee of mine employees waited on H. S. Gay, Jr., the general manager, and insisted that a bond-buying boss handle the stable or they would not go to work.

And now a report from Illinois. Miners employed at the Kortkamp mine, near Hillsboro, refused one day last week to be lowered into the mine or hoisted out of it by an engineer who was not loyal enough to buy a Liberty Bond. They took the position that a man who would not purchase a bond when working steadily at a good salary, was not only dangerous to the community but a source of danger to the men who placed their lives in his hands every time they entered or left the mine. They were frank to say that such a man might be disloyal enough to wreck the workings. The situation became so tense that the engineer called for his pay and left, and a bond-buying engineer was put in his place.

On May 11, Chairman Harry W. Coffin, of the Liberty Loan Committee, announced to the Alabama Coal Miners Association that the coal miners of Alabama had purchased more than $500,000 worth of Liberty Bonds of the third issue, showing that Alabama is not lacking in good citizenship.

One Day's Work for the Red Cross

The mine workers and operators of the Island Block Coal Co., of Island, Ky., a concern in the western part of that state, have already contributed a day's output to the American Red Cross. The miners put in a full day without pay, and the company donated 500 tons to the Red Cross funds. Not a single man failed to be in his place and the production for the day testified to the intense patriotism of the men.

Ostel Bullock, of Cleaton, Ky., furnishes the following story regarding some mines in Muhlenburg County, western Kentucky, which shows that the hearts of the miners are as tender as their hands are hard:

"Some time after the United States entered the war a difference arose between the mine workers and the operators as to the wage to be paid. In many cases strikes were the outcome and the production of coal was in consequence greatly restricted. The public censured the miners roundly, and some even said that the industry was a 'slacker.' This cut the miners to the bone, for they were more than willing to give their whole-hearted assistance to their country.

"They determined to show their patriotism and resolved at one of their union meetings to work one day without pay if the company would give to the Red Cross the equivalent of the selling price of the coal that the mine loaded on that occasion. There are four mines near Cleaton, Ky., and the output of the 'Red Cross day' was about 3325 tons. Sold at the Government price, this coal will net about $8000.

"One man who had not worked in the mines for several years decided to come back for one day to participate in this good cause. He loaded out 22 tons of coal, the record tonnage for the day. At least one mine, the Lam operation at Bevier, broke all its previous records. Every dog on the endless rope was working and only one dog during the entire day passed up the incline without its load of coal.

"The mine lost 35 min. by a derailment, and toward evening the loose coal in the mine was all loaded out so

MURPHY AT THE BAT FOR UNCLE SAM

that the plant had to be shut down 40 min. before the proper quitting time. Any one who failed to work on 'Red Cross day' by reason of sickness was to give his next day's work, and all were warned that if any man quit just before the day he would be required to contribute the largest day's pay still accruing to him.

"Every man, however, came out to work and stayed in the mine till he had loaded a full turn of coal. The Rogers Coal Co.'s mine, which is the 'Lam mine' aforesaid, donated 1280 tons; the Crescent Coal Co., 650 tons; the Bevier Coal Co., 225 tons, and the Holt Coal Co., 480 tons. All this shows that District No. 23, comprising western Kentucky, has some patriotic mine workers in its membership.

Perhaps here is a good place to rectify a statement regarding the western Kentucky miners of District No. 23, appearing on page 550 of the issue of Mar. 23, 1918. It ran as follows:

"The mine workers also recommended that the Government intervene to secure that powder be sold them by the operator at a lower cost. At the present prices no one but operators will sell miners powder, but that is not enough, they want the operator to accept an even larger loss in handling powder than that which they now sustain."

H. H. Vincent, secretary-treasurer of the district, declares this a misrepresentation, the prices ranging from $2.25 to $3 per keg and the average price being $2.50. He says that the wholesale price of powder does not exceed $2.15. On inquiry we learn from one union operator that the actual cost of powder as received by him is $2.12½ per keg. He assumes the cost of unloading it, the fire risk, the cost of hauling it into the mines and the cost of distributing it to the working places and charges the miners $2.50 per keg. He does not figure that any profit is made on the transaction. There is no agreement as to the price, but the operator informs us that the price seems to be general throughout the district and adds that the men are satisfied with both the price and with the way the powder is distributed.

A nonunion operation puts the price to the company at $2.15 to $2.25 and the selling price at $2.50. "The selling price of $1.75 per keg remained in effect for more than six months after the wholesale price of powder had increased to more than that figure. It was changed to $2 per keg July 15, 1917, at which time powder was again advanced to $2.50 without protest on the part of the miners."

Margins used to be about 75c. per keg, powder selling at $1.75 per keg that could be purchased delivered at 95c. to $1. The margin then was three times as large as it is today. In many mines competition had made it difficult or impossible to operate without loss, and the profit on powder, 75c. to 80c. a keg, helped the company to secure a safer balance sheet.

The mine workers it would seem should be willing to pay the 25c. to 37½c. per keg that is asked for the handling of this merchandise. It is only a small charge. On few sales of merchandise is so little as 10 per cent. charged for selling and distributing. Even the larger figure that we have noted—17½ per cent.—is not unreasonably large. Where $3 a keg is charged the companies demanding it might well be restrained by the Fuel Administration from such a course.

But this does not extenuate the misstatement made, and District No. 20 and its polite secretary-treasurer, H. H. Vincent, are entitled to a retraction. Surely one should not withhold apology from men who are so generous to the Red Cross.

Union Threatens Coal-Price Cutters

The United Mine Workers of America in Illinois and elsewhere have long suffered because they have had to work for "hardly-able" coal companies. It must be conceded that they got their pay invariably and on time, but the mines were not run as they would have been had the operators been successful business men instead of "pikers."

Everywhere things were skimped and allowed to run down. Further, the operators, in many cases opposed or were indifferent to the passage of laws regarding safety, because they knew that if the laws were passed the coal in neighboring states with less restrictive legislation would drive their coal out of the market.

Moreover, on every occasion in which the mine was idle the day men were laid idle also. The miners are fully convinced that they do not want to work any more for poor corporations, and the attempt of the railroads to buy coal at cost or less than cost finds the mine worker almost as much up in arms as his employer.

Frank Farrington, president of the Illinois United Mine Workers, has sent a warning to the presidents of the three operators' associations in the state that any cut in coal prices by the operators will be looked upon with suspicion by the miners, adding that price cutters may expect trouble from the organization. He points out that the prices made by the Fuel Administration have been carefully considered and adjusted and that a cut in prices would mean either that the operator must suffer a corresponding loss in profits or meet the reduction in price by lowering wages or by making the working conditions of the miners less favorable.

He says that the prices fixed by the administration are necessary if the operators are to be enabled to meet the legitimate cost of production and at the same time reap a reasonable profit. "In order," he says, "that the mine owners may keep their mines in the safe condition required by the state mining law, pay the wage scale provided in our joint agreement, furnish the miners with the working conditions they now enjoy, pay the indemnities provided by our compulsory compensation law in the event of injury or death occurring during the course of employment, and meet other legitimate items that enter into the cost of production, and, finally, reap a reasonable return on their investment, they must receive the prices designated by the Fuel Administration.

"At the present time thousands of miners in this state are working only one or two days per week, because many large consumers of coal, particularly some of the railroads, are withholding their purchases with the obvious intent of creating a competitive condition that will enable them to get their coal at a price lower than that designated by the Fuel Administration. This tends to create a panicky feeling among the mine owners causing a reduction of selling prices."

Frank Farrington adds that if consumers will begin now to lay in next winter's coal supply, instead of holding off with the hope of getting it at a lower price than that designated by the Fuel Administration, their action will furnish work to thousands of men in the state during the summer months who are now lying idle and who are extremely anxious to do their bit. It will also enable many men who have been liberal purchasers of war bonds and stamps and contributors to war funds to continue to perform their duty in this respect. They cannot do so if they are compelled to lie idle the greater part of the summer. He concludes as follows:

"As president of the 90,000 men employed in and around the coal mines of Illinois, I hereby warn you that any operator in this state who is guilty of any act that places the wages and the interest of the men who mine the coal in jeopardy will be regarded as being an enemy, and we shall be constrained to take such action as may be within our power to protect ourselves against his act of enmity."

Who Is "Within the Peace of the People"?

Slow progress is being made in the selection of a jury to try seven coal miners and four other men on the charge of murdering Robert P. Prager, the mine worker who was lynched at Collinsville, Ill., Apr. 5.

Better progress is now being made with the trial, for Sheriff Jenkins and his deputies and bailiffs have been disqualified. State Attorney Streuber made an affidavit that the sheriff, who was formerly a coal miner, and his men were prejudiced in favor of the defendants and had summoned as talesmen only those believed to be favorable to the interests of the defendants. Special deputies appointed by the court are bringing in better jury material.

The questioning of veniremen has disclosed that the defense is to be based on the unwritten law of patriotism. Attorneys for the defendants say they will prove that Prager was a German spy and will contend that Prager was not killed "within the peace of the people," as the statute reads, and being engaged in a disloyal enterprise took the same chances of being killed that the burglar takes. The attorneys contend that the defendants had the same right to kill Prager that a householder has to kill a burglar. State's Attorney Streuber says the state will show by Supreme Court decisions that the protection of the law extends, without any question whatever, to alien enemies, criminals and all others.

The defendants wear the national colors on the lapels of their coats. Many miners are attending the trial, including local and district officers. They have promised to show that Prager was a spy, but so far have not revealed the evidence on which they base their declaration.

The Dauphin County court awarded damages to the amount of $350 to three miners of the Susquehanna Coal Co., of Philadelphia, Penn., who sued the corporation for sums deducted from the pay for hard coal mined which the company declared to be below standard.

DISCUSSION BY READERS

After the War, What?

Letter No. 1—To a much interested though unbiased traveler in the anthracite and bituminous coal fields, a large number of the medium-sized and mostly all of the smaller operations appear to be adopting a restricted policy, which cannot but prove unwise, in respect to the future development of the coal industry, in that no provision is being made for the increased demand for coal that will unquestionably occur when the war has ceased. This prediction is particularly true, I believe, in respect to the bituminous mines.

Let me be perfectly frank and say that a great many of the mine operators, including some of the larger ones, have adopted the policy of saying that they do not know what the future holds for them, and, therefore, they will let well enough alone and make no plans whatever for the development of the properties they are now operating and much less for those in prospect.

Pessimism Among Some Coal Operators

Many coal operators take the viewpoint that the present government-regulated price of coal is only temporary. They predict that when the war is over the bottom will drop entirely out of business and the country will suffer a period of inactivity for a considerable length of time. They believe that this will greatly reduce the demand for coal and that the tonnage produced will exceed the consumption.

This line of argument, I am happy to say, is quite opposed to the thoughts of some of the leaders of American business enterprise, particularly the leading manufacturers of steel and its allied products. For instance, John Wanamaker (though I am quoting a leader in the merchandising business), addressing a meeting of the representatives of a certain trade organization, stated, "When the war is won there will unquestionably be a slight lull in business, until a certain readjustment is made," adding, however, "Such a readjustment will be necessary; but the cessation of big business will be very, very slight. Indeed, for at least four years following the cessation of hostilities the volume of business in this country will be greater than ever before, and the United States will enjoy an era of unprecedented prosperity."

Optimism of Large Manufacturers

Referring now to the largest steel manufacturers in the country, permit me to review briefly what they are doing. The steel corporation interests in West Virginia and Kentucky are making wonderful enlargements in the scope of their operations. The Youngstown Sheet and Tube Co. and the Inland Steel Co. are each opening up a large operation in western Pennsylvania. I might mention, besides, a number of other large new operations such as the Mather Coal Co., the Pursglove-Maher Coal Co., the Bertha Coal Co., etc.

One cannot fail to observe that the far-seeing business people and leaders of industry are preparing, at the present time, for the years of activity that are bound to follow the allied victory. To such will come the reward by reason of their ability to then produce what the world will demand, and that, in their judgment, will exceed the need of the present time.

If these larger corporations can, with entire safety, appropriate large sums of money for the development of new and old operations alike, it certainly follows that the managers of smaller propositions can proceed with entire safety to lay their plans for a large volume of business in the future.

In my opinion, the coal-mining industry should look forward to a large volume of business, for years to come, and should feel a positive assurance that the prices for coal will remain as high as they are at present, with a possibility of going even higher at a later date.

The subject is one worthy of the most careful consideration by coal operators of every class, and I express the hope that there will be a further discussion along this line, which I firmly believe will prove the truth of my conviction. If such is the case, operators must increase the efficiency of their haulage systems, by providing up-to-date motive power and other mine equipment that will be needed in the new development work required to meet an unprecedented demand for coal.

P. H. KENNEDY.

New York City.

Employment of Mine Labor

Letter No. 1—At a recent meeting of the American Institute of Mining Engineers, as reported in *Coal Age*, Mar. 23, p. 554, the members discussed the question of the utility of an "employment manager," charged with the duty of hiring all the men employed by a large industrial organization. The discussion presented some interesting phases applicable to the management of a large mine, and it would be interesting to know what the readers of *Coal Age* think of the suggestion.

Such an employment manager must be a person of ripe experience and judgment, who would be able to size up a man, so to speak, and determine his capability to perform work of a given character. He should know the organization and its requirements from A to Z, in order to determine an applicant's fitness for any position from janitor or office boy up the scale.

The scheme possesses the advantage that an employment manager would have the time and facilities to investigate the merit and worth of each applicant. Foremen know what kind of men they need, but their duties in the mine will not permit them to devote any time to look up a man's previous record. As a consequence, when a foreman hires a man he is obliged to test his capability by the manner in which he performs his work in the mine. At times this may result in serious loss.

A special feature to be considered in connection with the hiring of men, by the employment manager of a large coal-mining company, is the fact that such a company will generally have more than one mine in operation. A man found not adapted to the work or not satisfactory to the boss in one mine can then be sent to another mine, where he may have less difficulty in making himself useful.

While centralized hiring of men may be impracticable in certain large manufacturing plants, it occurs to me that the scheme can be successfully applied to large coal-mining corporations. In my opinion the superintendent of a large coal company, by reason of his long experience and responsibility, would be well fitted to select and hire the men required in the various branches of the work. It should not impair the foreman's authority in the mine when his men are hired by the superintendent, and it would relieve the foreman of that responsibility and permit him to devote his whole time and energy to the supervision of the work underground.

Foreman's Right To Discharge His Men

There will, no doubt, be those who will differ with me in regard to a foreman's right to discharge a man whose work is not satisfactory to him; but I believe such a man should be sent back to the superintendent for whatever disposition that official chooses to make of him. Unless the man is wholly irredeemable, he can generally be used to advantage in another position.

A motorman who may be incapable of performing his work properly under the conditions in one mine may prove a valuable worker in another mine where the conditions are more favorable. Likewise, a miner who fails to load clean coal in one mine or under one boss may be found wholly tractable when working in another mine where the boss is more affable.

When a man's work is unsatisfactory to the foreman, there are frequently two sides to the difference existing between them. The man may say that he cannot get along with the boss, while the boss will claim that the man will not do the work as he wants it done. If it is a question of the man persisting in having his own way and refusing to obey the instructions of the boss, it would indeed be a poor policy to allow such a man to go to work under another boss employed by the same company. Such a proceeding would destroy the authority of the first boss, whose men would soon learn to override him and do as they pleased.

Under the conditions just named, it would be natural for a boss to conclude that it was of little use for him to strive to make his mine a paying proposition if men who persist in having their own way can appeal to the superintendent and be sent to another mine or put to work on another job. However, I believe that such matters can often be handled with diplomacy and the difference adjusted by the superintendent, without the necessity of the company losing the man. It may be even within the range of possibility that the man could be reconciled to perform the work in the manner in which he was asked.

In closing, let me say that, notwithstanding these difficulties, I still believe that the hiring and discharging of men by the superintendent would place the labor problem on a more successful and scientific basis than it is under the present system. A foreman of sufficient experience and hardened to his work is usually fair-minded enough to want to see everybody get along. He is glad to see somebody else dispose of his unsatisfactory labor and is just as well pleased that someone else will hire the man.

Echoes from the Mine and Camp

Letter No. 2—The letter on this subject, *Coal Age*, Apr. 20, p. 756, signed "M.P.H.," interested me greatly. The writer explained many points that only a man working around the mine and living in mining camps knows. Speaking of the many respects in which the miner is capable of improvement, let me say that a volume could be written on that subject, but there are two points that are of special importance, and these relate to his improvement morally and socially.

In considering the means that can be adopted or the methods that can be successfully employed in the moral and social advancement of the miner, I would class these under the following heads: Education, Economy, Industry and Independence or Self-Reliance.

We will assume that the miner is a person capable of being educated. It is freely admitted that, as a general rule, the coal miner is not well informed on matters pertaining to his own uplift. Owing to the want of an early school education, the average miner today possesses little knowledge of the most simple elements and requirements for his own success in life. Nevertheless, I claim that he has far more intelligence than many are willing to give him credit as possessing, although there is much room for his improvement, both morally and socially.

Education the Greatest Factor

The greatest factor in one's moral and social advancement is education. By close study a man learns many facts that give him a broader outlook on life and a deeper insight into his surroundings. But this is not all of education. By close observation of others, a man learns much that will assist him to elevate his own standard of living.

The miner, like every other individual, must have a desire to educate himself by adopting these means. The desire for education is the sure foundation for its success. Where there is no desire on the part of the individual, efforts for his betterment can only end in failure. The first endeavor, therefore, must be to create the desire for education.

It is true, as stated in the letter to which I have referred, that there is too great a tendency to classify men according to their occupations. The result has been that the miner who toils underground is too generally regarded as little better than a serf, by many people who do not know that, among all the toiling millions in the United States, the coal miner is the most generous and liberal-hearted of men. The rank and file of miners are, today, proving their loyalty by the purchase of Liberty Bonds and subscription to the Red Cross and Y.M.C.A. movements.

The news of strikes and disturbances in coal mining camps and districts comes, to those unacquainted with

the conditions under which this class of toilers exist, as echoes of what they wrongly assume is the true character of the miner. In many instances it must be admitted that his false ideas of economy are responsible for these results.

Let me illustrate my meaning here, by saying that a miner obtains employment to mine coal at a fixed rate, per ton or per car, on condition that he will securely support the roof in his working place and throw out the bony coal and other impurities and load only good coal in his car. Like the rest of us, however, the miner is anxious to make big pay; and, to economize his time, he hurriedly sets but a few props in his place, and fails to give close attention to separating the impurities from the coal when loading his car. Contrary to his agreement to abide by the rules of the mine, many a time the miner will rob his pillar to obtain cheap coal.

Such acts and misdemeanors lead to trouble, and a strike is proclaimed. The real cause of the disturbance and seat of the trouble is the lack of education on the part of the miner and his false ideas of economy, which it is our duty to overcome and eradicate as far as this is possible. The miner must be taught that his interests and the interests of his employer are common.

Speaking of industry, the average coal miner is a hard worker. Practically the only exception to this rule is to be found in that class who are enslaved by the drink habit, and spend their time in the saloons, for days and weeks following pay at the mine. This is another echo from the mining camp, which gives a wrong impression of a true miner's character.

To save the miner, in this respect, the saloon must go. No success in moral or social advancement can be attained as long as it remains. Every effort must be put forth to accomplish this end, if we would better the miner's condition and educate him to be the industrious, independent and self-reliant worker that is needed.

Kingston, Penn. FRED B. HICKS.

Mass Education Needed

Letter No. 4—I recall reading a letter published some time ago on the need of educating the great mass of the miners employed in the mines. The letter set me to thinking on my own experiences in life during the past four decades.

When a very young man, full of energy, I commenced at the grass roots, in assisting to sink some very difficult and very deep shafts. When the shafts were down I continued to assist in opening and developing the mine. The work gave me some idea of coal mining, as there were clay veins and other difficulties encountered. In one instance, a dyke cut out the coal completely, necessitating the driving of a stone drift to again reach the seam. Various kinds of pumps were used to drain the mine, including one of the old Cornish type. Over a decade was spent in those mines, but in all that time I learned little and had no technical knowledge regarding my work. Let me say that what technical knowledge I now possess was gained from a school of mines where I studied later the principles of mining.

After coming to this country, I studied and obtained a first-class mine foreman's certificate, under the Act of 1893. This success gave me a renewed ambition, and I said to myself, "Here goes for lots of theory." But, pressure of circumstances robbed me of my opportunity to improve myself in a theoretical way. At times I was reasonably well located, and, at other times, I was forced into a very uncongenial situation.

Thus passed twenty years or more of hard study and labor. At one place I attempted to redeem a large abandoned machine mine. It took three or four years for me to discover that it was a useless undertaking. At another time, fortune favored, and I took hold of a new plant. Though I worked as hard as King Solomon's men in building the temple, I failed for the lack of a sufficient knowledge of theory.

My advice, in closing, is that young men should study to acquaint themselves with the principles of coal mining, while they are gaining experience in the practical work of the mine. Perseverance and hard study are sure to bring success in the end.

Men in Blind Alleys

Letter No. 4—The writers of the several letters following the Foreword on this subject, which appeared in *Coal Age*, Nov. 10, 1917, have without exception brought to light the most abominable practice existing in the industrial world today.

A superior in office or an employer who intentionally keeps his men in the same rut, without permitting them to advance original ideas or make suggestions of possible improvements in methods and equipment, is so narrow that he has no right to be clothed with authority to superintend a department or direct work.

The man who lives in fear that the men under him may possess an ability that will enable them to rise to his position; and who on that account, limits their activities, ignores their suggestions, or treats with contempt their efforts to improve his plans and methods, is an enemy to progress. No broad-minded superintendent or employer can afford to suppress the display of ability in men under his charge. They should be urged, on the contrary, to acquaint themselves with every phase of the work, both theoretical and practical.

I cannot agree with "Lumen" when he says "A young man is seldom willing to listen to the advice of an honest well-wisher, who has traveled the road before him and whose words should be an inspiration." My belief is that young men are quite generally willing to listen to the advice of older men whose experience is valuable.

YOUNG MEN ARE ANXIOUS TO LEARN

The young man, as I have observed him, thirsts after knowledge and asks to have explained what he does not understand. The young learn fast and one finds it difficult to fully satisfy their desire for knowledge. It is possible that the reference I have quoted alludes to a few specimens that one occasionally meets, who know it all and need to be told nothing. It is true that these, like the poor, we have always with us.

Organizations controlled by men who limit the activities of their workmen, by keeping them in ignorance of knowledge that will enable them to coöperate more successfully, quickly gravitates into an organization of slow, patient, plodding workers who show little vitality or "pep," as we say.

Compare such an organization, for a moment, with one that fosters the desire for knowledge on the part of every employee. Here, we find men being trained for doing better work and reaching a higher position. Every worker is fired with an ambition to know all about his own work and something of the other fellow's. The superintendent or employer invites suggestions from his men and, in some cases, offers bonuses for ideas that are accepted. It is not strange that an organization of this kind increases its business and its assets, year by year.

If progress in business is desired, every worker must learn the theory and practice of his work. Each man must be encouraged to advance, step by step, toward the next higher position, which will give him the ambition to perform well his present duties. The natural products of such a system are the development of executives who have a thorough working knowledge of the entire system, which alone insures the success of the undertaking.

Fair-minded men must see the merits of educating their workmen. The superintendent who is big enough, fair enough, and has the ability to perform will be promoted to a still higher position when the man under him rises to his place. Progress demands leaders who are clear-headed, thorough-going men. The march of progress automatically weeds out the weaker and more fearful men, whose places are quickly filled by stronger and broader-minded workers. FRED L. SERVISS.

Golden, Colo.

Explosion in Compresor Cylinders

Letter No. 1—Regarding the reference to the possibility of an explosion occurring in the compressor cylinder, made in a correspondent's letter, *Coal Age*, May 11, p. 893, I want to endorse the editorial comments following that letter as being well worth while.

Experience in the compression of air has taught me that carbonization takes place quite rapidly on the compressor valves and cylinder walls of the small portable compressors used in mine service. This can only be prevented by giving proper attention to the selection of a high-flash test oil and by a thorough cleaning of the compressor at frequent regular intervals.

Allow me to suggest that master mechanics and mine foremen will do well to make frequent inspection of the valves and cylinders of these portable compressors and see that they are kept clean and free from deposit. As a rule, these small, portable, motor-driven compressors are almost automatic in operation, and mine officials fall into the habit of giving them little or no attention, generally permitting them to run themselves, until their action gets so bad that complaint is made, in regard to the efficiency of the drills or coal-cutters. The result is that, in nine cases out of ten, the manufacturer is blamed.

Let me add, in closing, that if poppet, inlet and discharge valves on compressors, in the engine room, should be inspected and cleaned at frequent intervals, it is even more important that this should be done on the smaller portable compressors operated underground.

S. B. KING,

Chicago, Ill. Sullivan Machinery Co.

Working 10-Ft. Inclined Seam

Letter No. 3—Kindly permit me to offer a few suggestions that may assist "Superintendent" to solve his difficulties, which he has described in the inquiry, *Coal Age*, Mar. 23, p. 561.

The inquiry states that the coal is pitching from 15 to 20 deg., the seam being 10 ft. in thickness and troubled with faults and pinchouts. I understand from the description that the roof is of a shelly nature, making it weak and difficult to support, while the floor is a sandy shale.

It is unfortunate that the area of the coal property is not given, as that is an important factor in deciding on the plan of working and method of ventilating a mine. This is especially true when there are surface streams that must be considered in the development of the mine. Such features are liable to cause much trouble and expense in pumping if sufficient precautions are not taken to avoid this dfficulty.

GENERAL PLAN OF WORKING SUGGESTED

My first suggestion is to open the mine on the split-air system, so that it will be possible to ventilate each district of the mine separately and thereby control the circulation according to the need in each section. I would drive the main slope on the full dip of the seam, in the same manner as described by Andrew Bain, in his letter, Apr. 27, p. 803, driving three slopes abreast and making the center one of the three the main intake and haulage road for the mine. This would, in my opinion, be the most practical scheme for ventilating the mine safely and economically.

My second suggestion is to leave 3 ft. of coal up for a good roof, while driving entries and rooms in the first working. The coal being 10 ft. high, if 3 ft. is left for roof coal, the height of the openings will be 7 ft., which will give a good headroom for mules and cars after timbering the places. The cross-entries should be driven on a 1 per cent. grade in favor of the loaded cars. This will not only facilitate hauling but will afford good drainage for the mine.

In working the rooms, I would arrange to have two tracks in each room, so as to install a self-acting incline or gravity plane for lowering the coal from the working face to the entry. To do this I would make use of a rope and sheave by which the loaded car in descending would draw up the empty. The rooms can be driven from 18 to 20 ft. in width, but should have 30-ft. pillars between them. This will give plenty of room for double tracks, with a space for gob between them. MINER.

Springfield, Ill.

First Aid to the Uninjured

Letter No. 5—At this time, when every available unit of our resources must be hurled against the common enemy, the conservation of life and health is extremely vital, and the question of giving first aid to the uninjured grows in importance. Every mining man can well afford to heed the suggestion and give such aid to men who are yet uninjured, but whose careless-

ness and neglect go far to increase the accident rate in our mines.

In rendering such aid to the uninjured, we are performing a real service to Uncle Sam and helping to do our bit in the great struggle. At the same time, we are performing a lasting service to the man who is yet uninjured and to his family. The country calls for this service in the preservation of life and health, particularly at the present time. Though the men we strive to help may not appreciate our solicitude in their behalf, the task before us is not altogether a thankless one.

In the past few years volumes have been written on the subject of "safety first," and numerous campaigns have been conducted with the same aim and purpose. There are but few instances in which the efforts thus put forth have failed to bear fruit; but, still, the carelessness and neglect of the average miner continue to exact an appalling toll on life and health, although these are of the first importance to the industry and to mankind in general.

All will agree that it is our duty to concern ourselves more seriously with this important matter. Attention has often been called to the fact that statistics show that a larger number of lives are lost annually by reason of falls of coal and roof, at the working face, than from any other cause in coal mining; or, indeed, from all other causes combined.

If one takes the trouble to observe carefully, however, he will find that this class of accidents is less common at certain mines than at others working under the same conditions. He will find that the reason for this is evidently the lively interest taken in first-aid and welfare work by the mine officials at such mines. They are all making earnest efforts to reduce the accident rate to a minimum and the result is gratifying.

One observes with pleasure and satisfaction that, almost without exception, in mines where it is the custom of one or more of the mine officials, superintendents, mine foremen and his assistants, to visit every working place one or more times each day and instruct and discipline the men, the latter as a class become more conscientious in their efforts to avoid danger.

Where such efforts are put forth by the mine official, the miners are not slow to appreciate the fact that this interest is taken in their behalf, and they show a greater interest in their own safety. In such mines we find an enduring safety-first movement. The truth of these statements can be verified by anyone who will take the trouble to investigate those neighboring mines where such a policy is pursued and the working places are invariably inspected, each day, by conscientious mine officials. In my opinion this is the surest and most practical way in which we can render first aid to the uninjured.

SUPERINTENDENT.

Thomas, W. Va.

What Caused the Explosion?

Letter No. 2—An inquiry in *Coal Age*, Apr. 6, p. 645, asked for suggestions as to the possible or probable cause of an explosion, which is said to have occurred in a mine that had been standing idle for a period of two months. It is stated, further, that no one was in the mine at the time the explosion occurred, but it was found, later, that the blast started in a wet portion of the mine, which had been supposed to be free from gas and where natural ventilation only was employed.

Kindly permit me to suggest that sufficient gas may have been generated in this mine to have caused a considerable accumulation of firedamp, during the long period of idleness, when it is natural to suppose no attempt would be made to ventilate the workings by extending brattices to cause the air current to sweep the working faces and the many void places where gas might lodge. It is possible that this accumulated gas may have been carried to the foot of the 32-ft. shaft where it was possibly ignited by a lighted cigar stub or match thrown carelessly into the shaft.

Explosion Caused by Lightning

In one instance, I remember an explosion occurred in a mine when nobody was underground, and the cause of the explosion appeared a mystery until it was found that the iron pipe, standing a considerable height above the surface of the ground and which served to drain the gas from the mine through a 6-in. borehole, had been struck by lightning. It was assumed, in that case, that the lightning ignited the gas and caused the explosion underground.

Again, it may be supposed that firedamp had accumulated in the waste and that the falling roof striking some sulphur balls in the gob may have caused the sparks that ignited the gas and caused the explosion.

Ignited Gas Feeder Causes an Explosion

A remarkable instance of a mysterious explosion was reported a few years ago as occurring in a mine in western Pennsylvania. It was said that no one was in the mine at the time of the explosion, which occurred on Sunday. Neither had anyone been in the mine the Saturday night previous. Such was the force of this explosion that overcasts were blown out and several mine cars were broken into fragments, the remains of which I saw later. Most remarkable of all, however, was the fact that the blast tore loose, from its place where it was spiked, a 40-lb. engine-road frog, which was never found afterward.

This disaster was not discovered until early the following Monday morning, when the fireboss entered the mine to make his examination. In explanation of the probable cause of the explosion, it was decided that a small feeder of gas had been ignited by a shot of black powder and had escaped attention and been left burning when the miners left the mine Saturday night.

It was the custom, at this mine, when quitting to shut off the steam from the fan engine, upon which the speed of the fan was reduced from 75 to 18 r.p.m., the fan being run at this speed by reason of a condensing arrangement, which was operated by a small head of water supplied by a nearby creek. The reduced speed of the fan was insufficient, however, to keep the mine clear of gas, which it is thought accumulated and was carried by the air to where it became ignited by the burning feeder.

LUMEN.

Perryopolis, Penn.

Contributors are cautioned not to omit giving their names and addresses, which will not be published if so requested, and to write on one side of paper only.

INQUIRIES OF GENERAL INTEREST

Detection of Mine Gas

In the course of our work here much interest has been aroused in regard to the detection of mine gas, in daily practice. The question as stated is as follows:

Suppose a man with a standard safety lamp goes 60 ft. into a gangway and his lamp is put out by gas. Is there any positive way by which one can detect with certainty the nature of the gas that extinguished the lamp? It has been claimed, in arguing this question, that a body of methane will extinguish a lamp as quickly and as surely as blackdamp. INQUIRER.

Upper Lehigh, Penn.

It is true that a body of pure methane unmixed with air will extinguish a lamp as quickly as an accumulation of carbon dioxide or blackdamp. Indeed, the lamp may be extinguished by a mixture of methane and air, when a high percentage of the gas is present and there is not sufficient air to support combustion. Such a mixture is above the higher inflammable limit of the gas. It is even possible for the lamp to be extinguished below this point if the oxygen of the air has been depleted.

In general, pure methane or methane mixed with air, owing to its lesser density, is found at or near the roof in mine workings, while carbon dioxide and blackdamp, being of greater density, accumulate at the floor. In practice, the position of the lamp at the time it was extinguished will often show what gas is present.

However, this is not a universally safe rule, since it is possible for diffusion of these gases to take place in a manner that will alter the density of the mixture and cause the gases to assume a position in the entry contrary to their nature when pure. A similar effect is produced by the relative temperature of the gas and air currents; the warmer medium always seeking the roof, its density being less by reason of its higher temperature This feature of testing for gas was fully treated in answer to an inquiry, *Coal Age*, May 11, p. 894.

In reply to the question asked, it may be stated that, in order to determine the nature of the gas by which a lamp is extinguished, it is necessary to take into consideration not only the position of the lamp in the entry but the temperature of the currents passing at the roof and the floor, and to observe carefully the action of the flame previous to its extinction.

When a lamp is extinguished by carbon dioxide, or by blackdamp (which is generally a mixture of carbon dioxide and nitrogen, the oxygen of the air being depleted), the flame of the lamp is gradually dimmed for a considerable time before it is finally extinguished. On the other hand, if the extinction of the lamp flame is due to sharp gas, pure methane, or a flashdamp mixture of methane and carbon dioxide with more or less air, the action of the flame previous to its extinction will show a tendency to "capping." The cap produced in a flashdamp mixture must be observed quickly as it disappears almost as soon as formed, and the extinction of the lamp can only be prevented by withdrawing it from the mixture. The extinction of the lamp by a mixture containing methane occurs quickly, while the flame will often show a considerable disturbance or be elongated before it is put out by the gas. It is these appearances previous to the extinction of the flame that reveal to the experienced fireboss the character of the gas present.

Force of a Hammer Blow

A question that was much discussed in our meeting, recently, is how to figure out the force of the blow of a steam hammer, knowing the steam pressure, the area of the piston and the weight of the hammer head. Does the force of the blow change according to the kind of material struck by the hammer? Also, allowing a greater piston travel, would that affect the striking force of the hammer? We would like to see these questions discussed in *Coal Age*. SECRETARY.

Upper Lehigh, Penn.

It is possible to calculate the energy stored in a hammer at the moment of striking a blow. This stored energy, however, is expressed in foot-pounds. It shows the capacity of the hammer for performing work, and work is the product of two factors, force and distance. In the case of a hammer, the stored energy at the moment the blow is struck is equal to the force of the blow multiplied by the distance through which the hammer moves while being brought to rest by the resistance of the material struck.

For example, if a 2-lb. hammer strikes the head of a nail with a velocity of 10 ft. per sec., the energy stored in the hammer at the moment the blow is struck is

$$\frac{Wv^2}{2g} = \frac{2 \times 10^2}{2 \times 32.16} = 3.109\ ft.\text{-}lb.$$

Now, if it is found that the nail was driven in ¼ in., which is 0.0208 ft., the force of the blow is 3.109 ÷ 0.0208 = say 150 lb., nearly.

In the case of a steam hammer the total steam pressure on the piston is found by multiplying the area of the piston by the unit pressure of the steam, and to this product must be added the weight of the hammer head. The combined pressure and weight, expressed in pounds, multiplied by the distance, in feet, through which the hammer falls, will give the foot-pounds of work performed. But, to find the force of the blow delivered, it is necessary to divide the foot-pounds of work stored in the hammer by the distance the hammer moves while its motion is being arrested by the resistance of the material struck. A greater piston travel gives a greater striking force to the hammer; but the actual force of the blow delivered will depend on the density of the material struck, as this will determine the distance in which the hammer is brought to rest.

EXAMINATION QUESTIONS

Illinois Mine Manager's Examination April 2, 1918

(Selected Questions)

Ques.—There are 125,000 cu.ft. of air per min. passing through an airway 7 x 9 ft. in section. The temperature of the air is 62 deg. F., barometer, 30 in.; what would be the horsepower producing ventilation, less the friction?

Ans.—The meaning of this question is not clear, as it is customary to estimate the horsepower producing a circulation of air in a mine or airway, from its frictional resistance, by multiplying the resistance due to friction, expressed by the formula ksv^2, by the velocity of the air current and dividing by 33,000.

The energy represented by a given *weight* of air moving at a given velocity, in the ventilation of a mine or airway, has no significance in determining the horsepower producing the circulation. In the given instance, the velocity of the air is $125{,}000 \div (7 \times 9) = 1964+$ ft. per min. The weight per cubic foot of this air, at the given temperature and barometer, is

$$w = \frac{1.3273 \times 30}{460 + 62} = 0.0762\ lb.$$

The total weight of air passing per minute is therefore $125{,}000 \times 0.0762 = 9525$ lb. The energy stored in this weight moving at a velocity of 1964 ft. per min. (32.73 ft. per sec.) may then be calculated as follows:

$$H = \frac{Wv^2}{2g(33{,}000)} \qquad \frac{9525 \times 32.73^2}{2 \times 32.16 \times 33{,}000} = 4.8\ hp.$$

This may be considered as the horsepower absorbed in setting the air in motion; but it is not the horsepower producing the circulation, which is very much greater.

Ques.—With a 50-hp. fan we are producing 110,000 cu.ft. of air per min., what quantity will be produced with 75 hp.?

Ans.—Assuming that the efficiency of the fan remains constant when its speed is increased to produce more air, the conditions in the mine remaining unchanged, it is customary to estimate the volume of air as varying with the cube root of the horsepower. In other words, the volume ratio is equal to the cube root of the power ratio. Hence, calling the required volume of air x, we have

$$\frac{x}{110{,}000} = \sqrt[3]{\frac{75}{50}} = \sqrt[3]{\frac{3}{2}} = \sqrt[3]{1.5}$$

$$x = 110{,}000\sqrt[3]{1.5} = 110{,}000 \times 1.145 = 125{,}950\ cu.ft.\ per\ min$$

Ques.—Define a "dead hole," as described in the mining laws. Describe the duties of shotfirers in mines where more than two pounds of powder is used in one blast, also, in mines where marsh gas is generated in dangerous quantity.

Ans.—The definition of a "dead hole," as given in Sec. 19 (f), is quite vague as to its meaning. The law states that a "dead hole" is a hole where the width of the shot at the point, measured at right angles to the line of the hole, is so great that the heel is not of sufficient strength to at least balance the resistance at that point. The meaning of the law is not clear.

A better definition of a "dead hole" is that already given in *Coal Age*, Vol. 9, p. 511, which reads as follows: A "dead hole," in blasting, is one in which the charge is so located that it cannot perform the work intended, or a hole in which the line of least resistance corresponds more or less closely to the axis of the hole.

The duties of shotfirers in both the classes of mines mentioned is to inspect and fire all blasts that have been prepared in a practical workmanlike manner, in the mine. Immediately after completing this work, the shotfirer shall post a notice in a conspicuous place, at the mine, stating the number of shots fired and the number not fired, if any, specifying the number of the room and the entry and giving the reasons why such shots were not fired.

The shotfirer is also required by law to keep a daily record of the number of shots fired, the number of shots failing to explode and the number that, in his judgment, were not properly prepared and which he refused to fire. This record shall be given in charge of the mine manager (mine foreman) and be available for inspection at all times, by interested parties. The law forbids the firing of any shots by the shotfirer before all the workmen have left the mine, and makes it unlawful for a shotfirer to fire any shot that, in his judgment, is not a workmanlike and practical shot.

Ques.—The velocity of air passing through a coal mine is 225 ft. per min. The entry, at the place of measurement, is a concrete arch 10 ft. high, 8 ft. to the springing line and 8 ft. wide. What are the perimeter, area and quantity of air passing per min.?

Ans.—The rectangular portion of this airway is a square 8 ft. on each side. The arch has a rise of $10 - 8 = 2$ ft. The radius of a circular arc whose chord is 8 ft. and center ordinate 2 ft., is found by dividing the sum of the squares of the half-chord and the ordinate, by twice the ordinate, which gives, in this case, $4^2 + 2^2 \div (2 \times 2) = 5$ ft. The angle subtended by half the arc is an angle whose sine is $\frac{4}{5} = 0.8$, or 53° 08′, or 53.13 deg. The length of this arc is, therefore, $53.13/180\ (3.1416 \times 10) = 9.27$ ft. The total perimeter of the airway is, therefore, $8 + 8 + 8 + 9.27 = 33.27$ ft.

Likewise, the area of the sector subtended by the same arc is $53.13/180(0.7854 \times 10^2) = 23.18$ sq.ft. Then, deducting the area of the triangle, formed by the two radii drawn to the extremities of the chord, which is $\frac{1}{2}(3 \times 8) = 12$ sq.ft., gives $23.18 - 12 = 11.18$ sq.ft. for the area of the segment under the arch. Adding this to the area of the rectangle, $8^2 = 64$ sq.ft. gives $64 + 11.18 = 75.18$ sq.ft. for the sectional area of the airway. The quantity of air passing in this airway is then $75.18 \times 225 =$ say 16,900 cu.ft. per min.

COAL AND COKE NEWS

Harrisburg, Penn.

The departure of several hundred miners from the anthracite region on May 16 was followed by a protest from members of the anthracite operators' committee, who express themselves as alarmed over the possibilty of a severe coal shortage resulting from the drain on highly technical labor.

In a statement issued by the operators attention was called to the fact that every miner taken away means the training of another able-bodied man to fill his place, a course of training requiring two years. The two-year apprenticeship is required by the state law before a miner can obtain a certificate or license.

The present number of miners, it was said, is barely sufficient to maintain a maximum of 275,000 tons daily. There are now 153,000 miners, or 24,000 fewer than there were before the war. In describing the effect of constantly drawing mining labor away to other service, the operators said: A miner with his laborer, with effort, can get out eight tons of anthracite daily. A miner being taken away, the laborer cannot work and the resultant loss in output means 208 tons for 26 working days, or 25,000 tons a year for 312 working days. Allowing ten tons of anthracite for winter consumption, means also that 2500 families would be deprived of coal for every registered miner lost to the industry.

An estimated 1,000,000,000 hp. has gone to waste in the past ten years in the 2,000,000,000 cu. ft. of mine gas that is known to have escaped from a single borehole in the vicinity of Luzerne Borough, Luzerne County, according to reports made to W. S. Tompkins, of Wilkes-Barre, by engineers he specially engaged to inquire into the waste of mine gas, which it is proposed by Governor Brumbaugh to put to use in the future as a substitute for coal in various sections of the anthracite field.

This gas has been escaping from the top of the Snake Island vein, which at that place has not sufficient rock cover to permit the mining of coal. This offers substantial proof to what has been asserted before, that there is a large territory in the anthracite fields where the upper vein has not sufficient rock to remove the coal, but does contain methane or mine gas in large quantities.

Great interest is being shown in the investigations that are being made. It has been well established that there are millions of cubic feet of mine gas going to waste daily in the anthracite fields. Experts have declared that this gas can be mixed with air and used successfully for commercial and domestic purposes.

Charleston, W. Va.

In the field covered by the Kanawha Coal Shippers Association, according to figures recently compiled, in the period from May 1 to May 16 there were 19,572 empties received and 18,350 loads delivered. A wreck at Huntington about the middle of the week, however, disrupted coal traffic on the Coal River division of the Chesapeake & Ohio, and the car movement there was at zero, the same cause operating to tie up coal traffic to some extent for two days — Wednesday and Thursday — in the Kanawha region elsewhere.

Just at a time when it seemed the number of cars furnished would enable the coal producer to speed up, the operators met with further discouragement when the Virginian Power Co. caused a shutdown in three fields in this section of the state through failure to furnish power. The shortage was so generally felt that T. L. Lewis, secretary of the New River Association, sent a telegram to Dr. Garfield, United States Fuel Administrator, explaining the situation, in the course of which he said: "Coal mines in New River and Winding Gulf districts of West Virginia idle and supply of navy and bunker coal is endangered. Miners compelled to climb out of shafts of mines, and mules and horses cannot be hoisted out of the shafts. Reported the Virginian Power Co. responsible for closing mines by their failure to furnish power and to keep employed sufficient number of electricians to equip power plant on account of refusal to pay electricians more than $75 per month. Conduct of the management of the Virginian Power Co. is an outrage because it closes the mines and denies the miners an opportunity to work and reduces the output of coal required for the United States navy and other Government purposes. Virginian Power Co. has been granted two 10 per cent. increases in their rates for power supplied to the coal mines."

Operators in the New River district report a marked improvement on both the Virginian and the Chesapeake & Ohio railways. The supply within the last 10 days has increased, and the mines as a result have been shipping more coal. The Virginian R.R. has just received five new locomotives, and some attribute the increased supply of cars to such additional power, as the old locomotive equipment was in poor condition.

Operators on the line of the Coal & Coke are receiving a better supply of cars now than has been the case for some time, the Kanawha & Michigan Ry., for instance, having turned over 50 cars to the Coal & Coke at this point last Friday night. Inability, however, of the Kanawha & Michigan to accept loads from the Coal & Coke may delay the distribution of the cars received by the Coal & Coke. The great trouble among the Coal & Coke operators has been that when the car supply was good the labor supply was short and vice versa.

There was a most decided slump in the car supply in the Fairmont region last week, conditions there resembling conditions during the first two weeks of April, when the slump was so discouraging. While at the beginning of the week with a supply of 1427 cars, it looked as if there might be a good week, the shipping facilities afforded steadily declined from day to day, until the latter part of the week, when the number of cars furnished had dwindled to 642. For instance, on Thursday, of 166 mines reporting, 50 were closed, there being 4418 men out of employment and the production loss being 39,900 tons.

Fewer new operations may be looked for in the future, owing to the order of the railroad administration placing restrictions upon the authorization of new sidings, according to both coal men and railroad officials. In cases, however, where companies have taken out charters and invested in plants, entering into contracts with railroad companies for the placing of sidings, it is believed that special dispensation will be granted by the railroad administration and that such concerns will eventually be able to operate. Such special dispensation is the exception rather than the rule, however, and the new ruling is already making itself felt in West Virginia, questions put to operators eliciting invariably the reply that there are no new concerns venturing to open up due largely to the fact that they are unable to secure sidings from the railroad company.

Birmingham, Ala.

Among development announcements gaining circulation during the week is the reported plans of the Railway Fuel Co., which provide for the enlargement of the concern's coal-mining operations at Parrish, Ala. The company's mine at that place will be remodeled and equipped for electrical operation. W. E. Leake, vice president of the company, will be in charge of the work.

The Davis Creek Coal Co. announces the opening of a coal mine near Adger and a new coal company, under the name of the May & Phillips Coal Co. has been organized at Dora, Ala. John D. Phillips is president of this latter concern.

W. H. Ebsary, of Buffalo, N. Y., has been awarded the contract for the brick construction for the furnaces and buildings at Ensley, to be erected by the Tennessee Coal, Iron and Railroad Co. This contract represents an outlay of $100,000, and it is estimated that 6,000,000 brick will be used in the construction work.

Information gathered from the coal-mining section during the week indicated that the producers expect to be able to announce material improvement in production and quality of coal during the remainder of the current month. The miners started to work May 17 under the advanced wage scale, and beneficial results are looked forward to. Shortage of workers and inefficient labor, however, is still complained of in many quarters and will operate against material increase in production.

J. B. DeHopper, named by the Government as coal inspector to see that the cleanest coal possible is mined and shipped, has got to work and results are already being noted. However, reports reaching Birmingham indicate that while labor at many of the mining camps in Alabama appears to be as plentiful as it ever was, there seems to be some sort of depreciation in the quantity of the work accomplished and the results attained in actual production.

Winnipeg, Man.

The announcement of T. R. Deacon, fuel controller of Manitoba, that no American anthracite will be shipped to points west of Winnipeg, has created considerable alarm among consumers. Much attention is being devoted to the question as to whether a sufficient supply for next winter can be secured from Western operators. Local representatives of the Coal Sellers, Ltd., the largest wholesale coal distributors of Western Canada, which handles the output of seven Alberta mines with a yearly tonnage aggregating about 1,000,000 tons, state that the company could ship 500 tons daily to Winnipeg and increase this tonnage to 800 or 1000 tons daily in a short time. These coals could be stocked without serious deterioration and are high-grade domestic coals. The company has already stored in Winnipeg some $100,000 worth of coal for next winter. The Winnipeg dealers, however, are withholding their orders as they still entertain hopes of procuring hard coal. W. J. Dick, a western coal expert, formerly mining engineer for the Canadian Conservation Commission, and now fuel engineer for Coal Sellers, Ltd., states that the talk about Western coal not possessing the necessary heat required for a Winnipeg winter is absurd. He is prepared to prove this by a public demonstration, and to furnish data on government tests showing the high heating value of the Western coals handled by his company. He can also supply data respecting the testing of practically identical American coals in domestic heating furnaces. Jesse Gouge, president of the Newcastle Coal Co., of Drumheller, Alta., states that for the next 100 days Western Canadian mines will be in a position to supply large quantities of coal to Manitoba and Winnipeg. After that time it will be more difficult to ship coal on account of the increased demand and transportation difficulties. Western domestic mines have enough miners to operate steadily, and many of them are putting in coal-cutting machinery and car-loaders to take the place of man-power. He said in regard to deterioration from storage that if Western coal were stored in basements, or under cover, the best grades could be kept for a year without any deterioration. Western coal had eliminated the competition of anthracite in Saskatoon and Regina, where the winters were fully as cold as in Winnipeg.

Atlantic City, N. J.

The first annual convention of the National Retail Coal Merchants' Association ended a two-day convention at the Hotel Traymore, on Tuesday night, May 21, with a banquet at which the speakers included Joseph B. Dickson, of the Anthracite Committee of the Fuel Administration; A. W. Calloway, in charge of bituminous distribution for the Fuel Administration, and F. A. Lewis, Fuel Administrator for Philadelphia.

Mr. Calloway told the diners that the estimated requirements of bituminous for this year totaled 650,000,000 tons and that this might be increased to 680,000,000 tons by July 1.

Mr. Dickson urged rigid conservation owing to the lack of man-power and increased demand. He said that about 79,000,000

tons of anthracite had been distributed during the year 1917-1918, of which about 30 per cent. was steam sizes. Referring to the lack of supplies, Mr. Dickson said that at the beginning of last year there were 3,200,000 tons in storage, while there was none this year.

The convention was attended by coal men representing at least 20 states, and its membership includes 75 per cent. of the dealers of the country. It was organized about six months ago.

Resolutions were adopted strongly protesting against "Coal Week" as advised by the Fuel Administration, and a telegram was sent to Dr. Garfield, the National Fuel Administrator, stating that there was not coal enough to warrant such a demand for fuel as will result from the efforts of the Fuel Administration to have orders placed for coal.

Resolutions were also adopted advocating a uniform price for domestic anthracite coals, allowing a fair profit to every producer and not restricting output.

W. Albert Smoot, Jr., of Alexandria, Va., was reëlected president; John E. Lloyd, of Philadelphia, vice president and Jesse E. Sutter, of Washington, D. C., secretary and treasurer. An executive committee, of which Arthur F. Rice, Commissioner of the Coal Merchants' Association of New York, is a member, was also elected.

PENNSYLVANIA

Anthracite

Parsons—Baltimore No. 5 breaker is almost completely razed. The structure was damaged by fire some time ago and the Delaware and Hudson Co. decided to tear it down.

Shamokin.—In keeping with its policy to centralize clerical work and conserve male labor, the Susquehanna Collieries Co. has announced sweeping changes in its office staff and handling of business. Men employed at the headquarters office for a number of years have been assigned to the collieries, where new offices will be erected for the transaction of all business. The main office will serve as a sort of clearing house for the most important matters. At the same time the company announced the appointment of William P. Caldwell as paymaster, succeeding Galen P. Hanley, retired, and of Byron W. Kriher, as chief clerk. William Geise, one of the engineers in charge of the reconstruction of the Government docks at Newark, N. J., has been engaged by the Susquehanna as constructing engineer.

Bituminous

Connellsville—The new coal shaft of the Mather Collieries, at Jefferson, Greene County, has reached the Pittsburgh vein at a depth of 340 ft. and is completed. Fifty miners' houses have been completed in the new town site, all equipped with bathrooms and electric light. Bids are now being received for street grading. The construction of the railroad along Ten Mile Creek between Millsboro and Waynesburg is being pushed as rapidly as possible, as is also the work of constructing the West Penn Power Co.'s pole line to the new mining operations.

WEST VIRGINIA

Algonquin—The Algonquin Coal Co. has let contract for the construction of 25 new frame houses for mine employees. G. B. Farrier, superintendent, states that the company intends doubling its present production. This company has loading facilities on both the Norfolk & Western and Virginian tracks.

Dott—The Turkey Gap Coal and Coke Co. will build 25 new frame dwellings to house its mine employees.

Fairmont—The election of E. B. Moore, as president, Frank B. Pryor as vice president and O. F. Lough as secretary-treasurer of the newly chartered Fairmont Byproduct Corporation, is generally construed to mean that the company is a Monongahela Valley Traction Co. project. J. O. Watson, president of the Monongahela Valley Traction Co., stated a few days ago that negotiations for the byproduct plant had been practically completed and that contracts would be executed in the near future. E. B. Moore, general manager of the traction company, and president of the byproduct company, having gone east for a conference with engineers and plant builders. It is said that the plant will consume over 2000 tons of coal a day including Sundays.

Buckhannon—As soon as a tramway which the company is installing is completed, the Barbour-Upshur Coal Co. will begin the shipment of coal from its mines in Harrison County, probably about the first of June.

Charleston—The Peytonia Mining Co., of which E. B. Snider is general manager, will open another mine in the Coal River field in the near future.

Thirteen miners who were caught behind a wall of fire when the main entry of the Mill Creek Cannel Coal Co.'s mine at Villa burst into flame from some undetermined cause on May 20, were found dead in the workings.

Mannington—Four hundred miners recently escaped death from flames or suffocation by means of a ladder 200 ft. in length leading from the depths of the mine of the Rachel Coal Gas Co., near here. The fire was at the mouth of the main pit and destroyed the compressor and power house, with a loss estimated at $65,000. The cause of the fire is unknown, but is believed to have been started from a spark from one of the dynamos. The mine will be out of commission for several months.

Wheeling—The large, new tipple of the Triadelphia mine, capable of loading from 60 to 80 cars per day, has been placed in commission. The old tipple will be removed in a few weeks.

Logan—Automatic sprinklers are being installed by the McGregor Coal Co. at its mine at Slagle, Logan County.

A tract of coal in Logan County will soon be developed by the Carr & Hall Coal Co., recently organized at Stollings. W. W. Hall, of Huntington; A. D. Carr and Frank Harman, of Logan, being interested in the new enterprise.

TENNESSEE

Nashville—J. S. Denton, chairman, and W. W. Baird, of the State Board of Control, recently returned from a trip to the mines in Herbert Domain and Brushy Mountain mines at Petros. It was reported that operation of these mines was greatly curtailed in April through an epidemic of la grippe that involved more than one-half of the prisoners working the mines, numbers being confined to the hospital wards, while three deaths resulted from pneumonia. Production was reduced greatly, and also profits. However, profits for the month ran over $37,000, as against $50,000 in March. It is believed that profits for the year will run about $500,000 if they continue as high as during the first four months. Preparations are being actively pushed for installing new power machinery, but this advantage may be largely offset by the constant reduction in the volume of prison labor through paroles, expirations, pardons, etc., and by the falling off of the number of prisoners received due to better conditions and the war.

KANSAS

Pittsburg—Mine workers employed in the Cleremont Coal Co.'s mine No. 16 have voted on an assessment of $5 per man for the support of the American Red Cross. This amount is to be paid $1.25 per month for four months. Thereafter the men will contribute, by reason of the same vote, the sum of $1 a month per man during the continuation of the war.

ILLINOIS

Springfield—Operators and board members of the United Mine Workers held a two days' joint board meeting here during the past week. Minor disputes were thrashed out in a manner satisfactory to both sides. Friends of Frank Farrington, president of the Illinois United Mine Workers, headed by C. J. Daly, started a boom during the past week for his nomination for the United States Senate. When Farrington, who is in Washington, was apprised of the movement he wired that he had not been consulted and declaring his purpose to continue serving as president of the mine workers.

The miners of Sangamon County have agreed to give $10,000 to the Red Cross. The 290 men employed at the Tuxhorn mine near Springfield have pledged to give $1 each a month as long as the war lasts. The money will be taken out of the men's pay, 50c. each pay, and turned over to the Sangamon County branch of the Red Cross. The first payment, however, May 30, will be $1 from each man. The mine was 100 per cent. on the Third Liberty Loan. The men employed at the Klondike mine near Springfield voted $550. The Jones & Adams men voted to give 50c. a pay for the duration of the war, a total of $250 to $275 a month. The men at Citizens' Mine A and Mine B voted $2 a man. At other mines the men voted to subscribe their pro rata of the $10,000.

Banners were presented to Local No. 2654 of Springfield, Local No. 6060 of Cantrall and Local No. 1908 of Auburn, for having made 100 per cent. in the Third Liberty Loan drive. Nigger Hollow Mine No. 2, near French Village, has won a 100 per cent. flag by subscribing for $37,500 Liberty Bonds.

Belleville—An injunction petition has been filed with Circuit Clerk J. F. O'Flaherty by Joseph E. Brehet against the Lattman-Reeb Coal Co. of Belleville. Brehet rented some coal land to Lattman individually, who in turn leased it to the coal company. The petition seeks to prevent the removal of the coal.

Miners in each of the 11 newly organized subdistricts of Illinois voted Tuesday, May 14, for president, vice president and secretary-treasurer. The subdistrict plan of organization was abandoned several years ago, when there were eight subdistricts, but the growth of membership necessitated adopting it again and it was done in accordance with action taken at the State convention at Peoria. The results have not been announced. Contrary to precedent, no general holiday was taken for the voting.

Foreign News

Coal Spur, Alta.—On May 14th an explosion at the Oliphant Munson collieries, caused by the blowing up of the powder magazine from some unknown cause, killed John Brownrigg, manager, and one of the mine blacksmiths, and seriously injured three others.

Nanaimo, B. C.—The Granby Mining, Smelting and Power Co., Ltd., is installing a new mining plant at Cassidy Siding, near here. Roberts & Schaefer Co., of Chicago, has been awarded the contract for the installation of the tipple equipment, which will include a Marcus picking table screen.

Edson, Alta.—The Grand Trunk Ry. will install a coal-mixing plant in order to combine three different grades of Alberta coal into a standard fuel to be used on all the locomotives of the system between Winnipeg and Prince George. This will increase the consumption of domestic coal by 200,000 tons per year. The plant, which will employ about 50 men, will be in operation early in August.

Queens County, N. B.—Active development is being carried on in the coal areas, where every effort is being made to mine coal in sufficient quantities to relieve the shortage. A large amount of Montreal capital has been invested in this field, which is 800 miles nearer the St. Lawrence markets than the New Glasgow mines. In addition to the Minto Coal Co., which is producing over 3000 tons of coal weekly, the following companies are operating in the Minto-Newcastle district: Avon Coal Co., Ridge Coal Co., Reed Construction Coal Co., McDougall Co., Midland Coal Co., Northfield Coal Co., Grand Lake Coal Co., and Smith & Merrithew, Ltd. The scarcity of labor is not seriously felt. Miners are receiving from $8 to $12 per day and ordinary laborers $2.50. Plans are being made for the opening of many new mines and a great increase in the output this season is anticipated.

Personals

R. E. Bowen, formerly assistant engineer for the Harlan Gas Coal Co., Harlan, Ky., has enlisted in the 27th Engineers for Government work in France.

L. A. O. Gabany, formerly with the Alabama Consolidated Coal and Iron Co. and the Southern Steel Co., of Birmingham, Ala., is now coke expert with the Peabody Coal Co., of Chicago, Illinois.

J. L. Perdue, for several years mine foreman for the Turkey Gap Coal and Coke Co., Dott, W. Va., has resigned to accept a similar position with the Solvay Collieries Co., Springton, West Virginia.

Justus E. Altmiller, general manager and engineer for the Diamond Coal and Land Co., Hazleton, Penn., has been elected president of the Hazleton Chamber of Commerce, succeeding H. A. Schmoll.

Melvin I. Bowen, formerly geneal superintendent for the Cambria Coal Mining Co. at Briceville, Tenn., has resigned that position and leased the Middleridge mine, operating for himself. He has moved his family to Coal Creek, Tennessee.

J. B. Simonton has been appointed superintendent of mines 88, 89, 90 of the Consolidation Coal Co. at Wyatt, W. Va.; vice George DeBolt, Jr., resigned. Mr. Simonton has been in the employ of the company for a number of years and his promotion came as a reward for the faithful performance of his duties.

Dan Franklin has resigned his position as mine foreman for the S. J. Patterson Pocahontas Co., Arista, W. Va., to engage with the Solvay Collieries Co., Marytown, W. Va., in the same capacity. This brings Mr. Franklin back to his former employers, he having worked for this concern for years as mine foreman at Springton, West Virginia.

H. B. Walbridge, lately of New York, has been appointed agent for the following companies: The Pawama Coal and Coke Co., Matoaka, W. Va.; Algonquin Coal Co., Algonquin, W. Va., and Deparren Anthracite Coal Co., Parrott, Va., with headquarters at Parrott, Va. Mr. Walbridge will serve principally as assistant to J. H. Parrott, general manager of these companies. Mr. Walbridge served for a number of years as secretary of the American Coal Co., New York.

Obituary

William W. Craig, a prominent business man of Montreal, Can., died on May 12. He was well known in connection with the stripping business and was the Montreal representative of the W. H. Bradford Coal Co., of Philadelphia, Penn. He was in his 73d year.

William Hamer, mine foreman at Jeanesville, Penn., for nearly 40 years, died at his home in that town on May 14. He began work as a boy of eight on the old Spring Mountain breaker, and continued at the same colliery through its changing fortunes until his death. He was one of the first students of the now famous School of Mines of Scranton, and had been mentioned by his company recently as having a clear record of no accidents for three years.

Coming Meetings

American Concrete Institute will hold its annual meeting June 24-26, at Atlantic City, N. J.

American Institute of Chemical Engineers will hold its summer meeting June 19-22 at Berlin, N. H.

Illinois and Wisconsin Retail Coal Dealers Association will hold its annual convention June 26 and 27, at Hotel Wisconsin, Milwaukee, Wis.

National Coal Jobbers Association will hold its annual convention at Buffalo, N. Y., June 4. Secretary L. Romanski, Old Colony Building, Chicago, Ill.

American Institute of Electrical Engineers' annual convention June 26-28 at Atlantic City, N. J. Secretary F. L. Hutchinson, 29 W. 39th St., New York City.

American Society of Mechanical Engineers will hold its spring meeting June 4-7 at Worcester, Mass. Secretary, Calvin W. Rice, 29 West 39th St., New York City.

National Coal Association will hold a meeting May 28 and 29 at the Bellevue-Stratford, Philadelphia, Penn. Secretary, J. D. A. Morrow, 707 Southern Building, Washington, D. C.

Southwestern Interstate Coal Operators Association will hold its annual meeting June 11 in the Keith & Perry Building, Kansas City, Mo. Secretary, C. N. Fish, Leavenworth, Kansas.

Illinois and Wisconsin Retail Coal Dealers Association will hold its annual convention June 26 and 27, at Milwaukee, Wis., with headquarters at Hotel Wisconsin. Secretary, Isaac L. Runyon, Chicago, Ill.

Trade Catalogs

"Puzzledmuch" meets "Sellemfast." International Motor Co., New York. Pp. 14; 9x6 in.; illustrated. Talking points on Mack trucks, cleverly illustrated by cartoons.

Coupled and Belt Types of Alternating-Current Generators. Crocker-Wheeler Co., Ampere, N. J. Bulletin 185. Pp. 4; 8½ x 11 in.; illustrated. Covers two- and three-phase, 50 kv.-a. and up.

Direct-Current Lighting and Power Generators. Crocker-Wheeler Co., Ampere, N. J. Bulletin 184. Pp. 4; 8½ x 11 in.; illustrated. Covers direct-connected and engine types (25 to 3750 kw.).

CR 3100 Drum Type Controllers. General Electric Co., Schenectady, N. Y. Bulletin. Pp. 4; 8 x 11 in.; illustrated. Specifications and details for series, shunt or compound wound motors; reversing or non-reversing, starting or speed-regulating duty.

CR 3202 Drum Controllers. General Electric Co., Schnectady, N. Y. Bulletin. Pp. 4; 8 x 10 in.; illustrated. Description of these controllers for slip ring induction motors, 110 to 550 volts, two- or three-phase.

Proper Care of Belts. Joseph Dixon Crucible Co., Jersey City, N. J. Booklet. Contains helpful suggestions for getting maximum results from belts, and in addition has several pages devoted to useful information of a general character.

Satisfaction or —. Armstrong Cork and Insulation Co., Pittsburgh, Penn. Folder. Pp. 4; 3½ x 6¼ in.; illustrated. Deals with the subject of industrial drinking water systems and shows the relation of drinking water to a satisfied force of employees.

Copes Boiler Feed Regulators. Erie Pump and Equipment Co., Erie, Penn. Booklet. Pp. 16; 5½ x 3 in.; illustrated. Data on this method of feed control, which enables peak loads of short duration to be carried with a more uniform working of the furnace.

Link-Belt Silent Chain—the Efficient Drive for Machine Tools. Link-Belt Co., Philadelphia. Book No. 312. Pp. 40; 6x9 in.; illustrated. An excellently prepared booklet, well illustrated, giving reasons and showing why the Link-Belt silent chain drive is the most efficient transmission for operating machine tools.

Economy in Cold Sawing. Earle Gear and Machine Co., Philadelphia, Penn. Bulletin. Pp. 16; 4x9 in.; illustrated. Describes the Lea Simplex cold metal saw. In the fore part is pointed out the points of superiority of design and operation of this machine. Machines are built in four sizes, both belt and motor driven.

Liquid Roofseal. Manhattan Paint Co., Cleveland, Ohio. Circular. Pp. 4; 6 x 9 in.; illustrated. Describes what is said

to be a genuine asbestos roofing in liquid form. It is claimed by the manufacturers that liquid Roofseal renews and reclaims old, worn-out roofs of every description by giving them a new top covering.

The Alleviation of Suffering. Williams Improved Stretcher Co., Wheeling, W. Va. Booklet. Pp. 8; 5 x 7 in.; illustrated. Describes an improved first aid and ambulance stretcher. The many improvements embodied in the design and construction of this stretcher have earned for it the title of "the most humane, portable, convenient and sanitary stretcher made."

Imperial Catalog No. 142. Imperial Brass Manufacturing Co., Chicago, Ill. Describes in detail the full line of Imperial welding and cutting equipment, and Imperial burning and lead-burning outfits. Reviews the history of welding and cutting and its relation to industry. Several different sizes of Imperial outfits are illustrated and described fully. The catalog will be sent free to any reader writing for it.

Industrial News

Charleston, W. Va.—Authority has been granted by the secretary of state to the Quaker Splint Coal Co. to increase its capital stock from $25,000 to $150,000.

Williamsburg, Ky.—The Star Gem Coal Co., of Williamsburg, has been incorporated with a capital of $1000. George T. Vaughan, Mary E. Vaughan and Robert H. Davis are the incorporators.

Chattaroy, W. Va.—The West Thacker Coal Co., of Williamson, has been organized and is planning for the immediate development of about 60 acres of coal lands, to have a capacity of about two cars daily.

Glen White, W. Va.—The E. E. White Coal Co. is considering plans for the erection of a new steel coal tipple at its plant to have a capacity of about 5000 tons of coal daily. The structure is estimated to cost $150,000.

Pittsburgh, Penn.—The Petrolia Coal Co., of Kittanning, has been incorporated with a capital of $50,000. The incorporators are A. L. Sheridan, John W. Robin, J. W. Fletcher, H. G. Gates, of Kittanning and William Leslie, of Parkers Landing.

Centralia, Penn.—The Lehigh Valley Coal Co. has awarded a contract for the construction of a new one-story coal washery to be located near Centralia, to cost about $20,000. A. H. Ramberger, Girardville, Penn., is the building contractor.

Alger, Wyo.—The Amalgamated Development Co. has placed a contract with Roberts & Schaefer Co., Chicago, for the construction of its new reinforced-concrete tipple, to be built at this place, and which will include a Marcus picking table screen.

Cleveland, Ohio—The Lincoln Bonding Co. has purchased outright and consolidated here the business, patents and good will of the Atlantic Welding Co., of New York City. The Lincoln Bonding Co. manufactures an electric bond-welding machine that is meeting with much favor in the coal fields.

Weston, W. Va.—The P. C. Lynch Coal Co. has acquired about 1077 acres of coal lands on Stone Coal Creek in Lewis County in addition to the 750 acres recently acquired on the Baltimore & Ohio R. R. between Weston and Gaston. The company is planning to expend about $200,000 for the installation of the necessary equipment for development.

Columbus, Ohio—For the first time in a long while wagon mines in the Hocking Valley along the line of the Hocking Valley railway were being supplied with open-top cars. This was in accord with an agreement by the railroad to furnish such equipment when cars for regular mines reached 100 per cent. of requirements.

Wheeling, W. Va.—Judge A. G. Dayton of the United States District Court has issued an order against the Elm Grove Coal Co. restraining that company from refusing to supply coal to the Wheeling & Elm Grove company on the ground that if the source of the fuel were stopped street car service would have to be discontinued.

White Star, Ky.—The White Star Coal Co., 120 Broadway, New York, has filed notice of an increase in its capital from $120,000 to $300,000, to provide for expansion. At the present time the company is developing approximately 1500 acres having a daily capacity of 1000 tons, and it is planned to increase the output to about 1500 tons per day within the next six months. W. L. Hammond is general manager.

Charleston, W. Va.—Clarksburg men are chiefly interested in a million dollar coal company just chartered by the Secretary of State to be known as the Mountain State Coal & Coke Co., which will operate mines and coke ovens in Athens and Morgan Counties, Ohio. The incorporators are H. W. Kopp, E. D. Tucker, Joseph L. Walton, J. H. McKelvy and B. E. Maxwell, all of Clarksburg.

Charleston, W. Va.—Shippers of coal in this district have been notified by A. H. Land, district representative of the United States Fuel Administration, that the order which provided that all coal mined east of Charleston must be shipped to the shipping board, has been rescinded and that operators are now free to ship their product anywhere within the zone into which they have been placed by the Fuel Administration.

Louisville, Ky.—At no time since automobile trucks came into use in the retail coal field have their advantages been as great as at the present time, when it is impossible to obtain drivers, men to store coal, unload coal, etc. Locally the retailers are making practically no effort to supply men for storing coal for customers, as all men that can be had are needed in unloading from cars and handling the delivery end.

Columbus, Ohio—The Colonial Coal and Supply Co. has opened a new retail yard on Cleveland Ave. which is a modern plant in every respect. Storage capacity for 8000 tons has been provided. One of the features of the plant is a loading machine by which cars can be loaded from the storage pile for steam purposes. The plant occupies a tract of land 250 x 1000 ft. The equipment will be of sufficient capacity to unload or load 2400 tons in 24 hours.

Hellier, Ky.—The Allegheny Coal and Coke Co. has been bought up by the Peabody interests and is now known as the Manufacturers Coal and Coke Co. The new concern intends to build 200 rectangular coke ovens in addition to the 150 ovens now in operation. The Peabody company, one of the largest individual coal producers in the United States, has mines and virgin coal fields in the states of Illinois, Indiana, Oklahoma, Washington, Virginia and Kentucky.

Columbus, Ohio—Activity at the docks of the lower lake ports is gradually increasing as the lake season gets under way. The Hocking Valley docks at Toledo loaded 117,249 tons and 2223 cars for the week ending May 18 as compared with 118,248 tons the previous week, making a total of 367,399 tons since the opening of navigation. The Toledo and Ohio Central docks loaded 64,000 tons the week ending May 17 as compared with 47,000 tons the previous week, making a total of 198,000 tons for the season.

Pittsburgh, Penn.—Declaring that the law of the nation must be upheld and that coal men and food men, together with other merchants affected by wartime legislation, should familiarize themselves thoroughly with the laws, Judge Thompson in the United States District Court on May 15 fined John E. Robbins and Frank H. Stewartson, local coal brokers, each $500 for violation of the fuel act by selling above Government price. The defendants pleaded guilty and said they did not understand the order. The fines were paid.

Columbus, Ohio—The State of Ohio is probably the only large consumer which has neglected to lay in its coal supply for the coming winter. But this is due to legal requirements, which prevents the Ohio Board of Administration to contract for any supplies before the money to pay for the supplies is in the treasury. The money for the fiscal year 1918-1919 will not be available until after July 1. At that time Purchasing Agent Lyons of the board will start contracting for several hundreds of thousands of tons for the 23 state institutions.

Charleston, W. Va.—The Big Hurricane Coal Co., a Wayne County corporation, with principal offices at Hubbardstown, was adjudicated bankrupt last week after a hearing before Thomas R. Shepherd, referee in bankruptcy. The hearing was brought on the petition of the Emmons-Hawkins Co. of Huntington, and other alleged creditors, who declared the company committed an act of bankruptcy in assigning certain tracts of lands and mining equipment to Randolph Bias, of Williamson. The company has been operating on Big Hurricane Creek in Wayne County.

Charleston, W. Va.—The Liberty Collieries Co. has been incorporated with a capital stock of $150,000, the incorporators being Herbert Hannigan and S. G. Smith, of New Lexington, Ohio; C. A. Smith, of Chillicothe, Ohio; M. E. Moore and C. H. Hetzel, of Charleston. The company has announced that it plans to specialize in the production of byproduct coal, having purchased a large tract of coal land on which it expects to start development in the near future. S. G. Smith, one of the incorporators, is auditor of Perry County, Ohio, and has other mining properties in which he is interested in this state.

Louisville, Ky.—Wiley B. Bryan, fuel administrator for Kentucky, in a recent report stated that the mines of Kentucky loaded out 5000 cars of coal more in April, 1918, than was loaded out in April, 1917, showing that consumers are stocking for winter requirements, or else the yards and steam consumers were generally short and laying in surplus stocks. However, if the mines have been able to produce that much coal over last year's production, it would go to show that the labor and car situation is somewhat better than it was at that time, although in the spring of 1917 the demand was somewhat off.

St. Louis, Mo.—At the first annual convention of the Mississippi Valley Waterways Association, held here recently, United States Senator James A. Reed of Missouri, the principal speaker at the convention, strongly urged the utilization of the Mississippi and other rivers in the transportation of coal as a solution of the car shortage. He said it was plainly the duty of the Government to increase the efficiency of the railroads and establish barge lines without counting the cost. The establishment of the barge lines, he said, would relieve the railroad congestion and the coal mines would be able to obtain the cars that they need.

Indianapolis, Ind. — The Indianapolis board of education has made a contract with the J. R. Morris Coal Co. of this city for the delivery of approximately 20,000 tons of coal for heating the school buildings of the city for the school year beginning in September. The price will be $4.98 a ton, a total expenditure of practically $100,000. The coal will come from the Tuxhorn mines at Keyes, Ill., and will be delivered first to a school coal yard to be established on property belonging to the school board between Wilkins and Ray Streets on the Illinois Central R.R. tracks. Later, it will be delivered to the school buildings as needed. The contract provides that all coal shall be in the yard by October.

Columbus, Ohio—The Federal Fuel Administration is taking up the price question in all producing sections of the Buckeye State with the exception of Pittsburgh No. 8 vein. Last week W. D. McKinney, commissioner, and James Pritchard, secretary, of the Southern Ohio Coal Exchange, presented the cost figures from the Hocking Valley, Pomeroy Bend and Crooksville districts. J. L. Lawler and Edward Evans represented the Jackson district, and A. A. Augustus looked after Cambridge. The Federal Fuel Administration is figuring on a new system of computing costs of production and it may result in an entire redistricting of the state for price-fixing purposes. No decision will be announced for some time.

Kingwood, W. Va. — With a view to greater coöperation in securing a better car supply and to an improvement of conditions in general, the West Virginia Northern Coal Operators' Association was organized at a meeting held in the courthouse here at which a number of operators who have mines along the line of the West Virginia Northern Ry., which runs from Morgantown to Rowlesburg, were present. E. G. Smith, of the Inland Fuel Co., was selected as temporary chairman and presided during the election of the following permanent officers of the association: A. T. Carnahan, of the Deaker Hill Coal Co., president; Guy Bonafield, of the Loubert Coal Co., vice president; E. G. Smith, assistant secretary and treasurer.

Madison, Wis.—The University of Wisconsin has issued a bulletin prepared by the Bureau of Municipal Research upon the general topic of municipal coal yards, with suggestions for their erection and operation. Oshkosh is the only city which has made appropriation for a coal yard, but Kenosha, Madison, Sheboygan, Eau Claire, Fond du Lac, Green Bay, La Crosse and Racine are also interested. Ashland built a temporary coal yard last winter when the situation became acute, and Eau Claire did the same. Marinette started a municipal wood yard as a fuel relief, and Wausau has taken certain steps toward municipal sale of coal. In all, 30 cities have been interested in one way or another in the supply of fuel as a municipality, and the bulletin sums up the experience of these 30 cities.

MARKET DEPARTMENT

Weekly Review

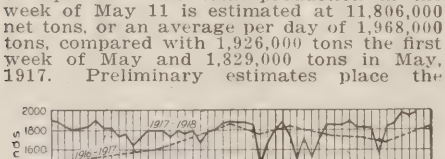
Coal Production Now Near Maximum—Must Conserve High-grade Fuel for Use of Essential Industries—Labor Situation Serious—New England Outlook Gloomy

WITH an increase in the number of empty cars furnished by the railroads, the bituminous mines shipped 11,806,000 net tons of coal during the week ended May 11—a showing slightly better than was made during the record week ended Apr. 27. Telegraphic reports indicate that for the week ended May 18 the output of soft coal bids fair to pass the 12,000,000-ton mark. Anthracite shipments for the week ended May 11 totaled 38,314 cars, a decrease of more than 5 per cent. when compared with shipments the week preceding.

The foregoing figures show nearly maximum production. But even if continued at this rate for the rest of the year, the country will still be faced with a fuel shortage unless immediate steps are taken to conserve every single ton. Railroads, power plants and other consumers that formerly burned high-grade coals should readjust their equipment and use the coals allotted their respective districts by the Fuel Administration, even if the coals so available are of an inferior quality. Only in this way will the vitally essential bunker, metallurgical and by-product demands be met and the domestic requirements be satisfied. Furthermore, it is becoming more and more apparent that plants other than those directly at work on supplies to aid in winning the war will receive little consideration so far as fuel is concerned.

The question of labor is now one of paramount importance. Sadly depleted by the draft and the return of many of its workers to the farms, the coal-mining ranks are being still further demoralized by the enticing appeals of war industries. Working on a cost-plus basis, munitions plants and shipyards offer almost any wage in order to get enough men. It would be well for the Government to put a stop to the havoc and labor unrest being wrought by this system in the coal fields. Otherwise we will be confronted by a shutdown of industries due to lack of coal that will make "fuelless Mondays" appear a godsend in comparison.

The railroad fuel question remains unsettled. Another month will see the termination of nearly all contracts for railroad coal, and both railroad purchasing agents and operators are in a quandary over what course to pursue.



Market conditions are strong and active in every way, with the demand for coal for storage purposes sufficiently large to take care of all the available fuel. While early in the season it was proposed to ship no domestic sizes of anthracite to manufacturing plants, it has already become necessary to make exceptions to this to the extent of over 2,000,000 tons for war work. The allotment for cantonments is also sure to be enormous, and probably much larger than at first considered necessary. It would be well, therefore, for domestic consumers who have not already done so to order their coal immediately, if they wish to make certain of getting a supply before cold weather.

Coal shipments into New England are falling down at the rate of about 20,000 tons a day. The railroads are doing all they can, and only by shipping more coal by water and the strictest kind of conservation will a fuel famine be averted in this highly important manufacturing section next winter.

The movement of coal to most of the lower Lake ports, for forwarding to Northwestern points, has reached a good volume. The ore movement is increasing also under the influence of a better coal movement. Practically all Lake shippers have now received their permits and are ready to go ahead in earnest.

COAL PRODUCTION

The continuation of favorable operating conditions, both of transportation and mining, during the week of May 11, are reflected in the production of coal, which gained 2.2 per cent. over the week of May 4 and exceeded slightly the record week of Apr. 27. The total production in the week of May 11 is estimated at 11,806,000 net tons, or an average per day of 1,968,000 tons, compared with 1,926,000 tons the first week of May and 1,829,000 tons in May, 1917. Preliminary estimates place the

week's production of beehive coke at 655,000 net tons, as compared with 647,000 during the week of May 4. The average daily production is estimated at 109,000 net tons, an increase of 1000 net tons per working day over last week. Improvement in transportation and better market conditions was reported for the country as a whole, although such improvement was partly offset by shortage of labor.

Beehive Coke—Repairs to plants effected a material improvement during the week ended May 11 in production of beehive coke. The yard labor situation, however, which limited production during the previous week, failed to record any material improvement. The principal operators in the Connellsville and adjacent districts of Pennsylvania report production of 388,395 net tons of coke. The ratio of tonnage produced to maximum capacity was 74.1 per cent. as against 70.4 per cent. the week of May 4 and 75.2 per cent. during the week ended May 11. The same operators shipped 140,150 net tons of coal.

Byproduct Coke—Operators of byproduct coke plants report production during the week ended May 11 at 89.2 per cent. of maximum capacity. The ratio of production to maximum capacity was lower than during the preceding week, and the slight decline is attributed to labor shortage at the Bethlehem steel plant at Northampton and the Cambria steel plant at Johnstown. The shortage of labor at these plants caused losses of potential capacity for the country as a whole to rise from 0.6 per cent. the week ended May 4 to 2.3 per cent. Losses attributed to lack of coal declined from 3.7 per cent. to 2.8 per cent., and losses due to repairs to mines and "no market" remained constant, the former at 4.5 per cent. of potential capacity and the latter at 0.3 per cent. Pennsylvania was the only state to report a material decrease, caused as previously stated by labor shortage, and these operators continue to report the least favorable conditions, operating at only 77.1 per cent. of their capacity. Considerable improvement is reported by Alabama, Kentucky and Maryland operators. Increased production of the operators in the two states first named is attributed to repaired plants, while the cause of the improvement in Maryland was not reported.

CARLOADS OF COAL AND COKE ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended Apr. 20	Apr. 27	May 4	May 11
Bituminous shipments, 123 roads	193,667	204,527	202,558*	207,159†
Anthracite shipments, 9 roads	39,130	39,522	40,570*	38,314†

* Revised from last report. † Subject to revision.

Anthracite shipments declined from 40,570 carloads during the week ended May 4 to 38,314 carloads during the week of May 11, a decrease of over 5 per cent.

Dry Goods Economist—The between seasons period now setting in finds many branches of the textile industries welcoming a breathing spell. The wool and worsted goods manufacturers are waiting to learn what quantities of raw materials will be left for them when the needs of the Government are finally determined. Cotton is still in ample supply, with prices of short staple fully 10c. under levels of two weeks ago. Fine cotton, such as is needed in the making of most dress fabrics, is not so plentiful, as is shown by the fact that prices have only receded 2½ to 3c. per pound. Linen is practically out of the reckoning for the time being.

Bradstreet's—Growth in war business, broader demand for civilian goods, improved retail trade, further ease in transportation, and excellent crop reports stand out as the principal factors in a budget of encouraging news. But governmental operations, ranging from the construction of ordinance plants, ships and warehouses down to the buying of the most common products, figure to a greater extent than heretofore. As the Government buys, as it continues to commandeer goods in being or in prospect, various kinds of supplies for non-militant consumers necessarily grow

scarcer. In short, the country's movements are being adjusted to a true war basis, and with few signs of friction.

American Wool and Cotton Reporter—Little activity is seen in the woolen goods market. Interest is largely centered in what will happen to civilian contracts now held by mills. Production is largely for Government requirements and prices are being regulated, not by the supply, but by the Government. In the cotton goods market there has not been the tendency towards a decline that there had been previously, and a much steadier tone of buying and selling has been in evidence. The outlook is uncertain. The market is in the balance and probably will continue so until some definite change in fundamental conditions.

The Iron Age—The most serious factor in the situation is the loss of three months' time in the placing of locomotive and car orders—a delay costing the Allies thousands of tons of steel that by no possibility can now be delivered in 1918. Some of the steel for the new cars has been allocated this week, including 135,000 tons of plates to the Steel Corporation. The total of plates, shapes and bars for cars is 922,110 tons, deliveries to be made in 120 days, beginning June 20. Important among the price adjustments announced on May 21 was a $6 per ton advance on cast-iron water pipe, a reduction of 25c. per 100 lb. for structural and ship rivets and 15c. for boiler rivets (a differentiation now being made) and a reduction of about 5 per cent. on smaller rivets. Copper-bearing low-phosphorus pig iron was advanced $2 per ton.

Atlantic Seaboard

BOSTON

Output continues disappointing. Car supply and railroad fuel questions still unraveled. Manufacturers not on preference list most anxious over outlook. Renewed efforts to close contracts on water coal, but those not already "covered" all-rail are discouraged. District representatives have hands full. State administrators busy lining up "requisitions." "Storrow coal" all-rail order not yet renewed. Hampton Roads coal not in even supply at piers. Boats still short. Some Lake-built steamers begin to arrive. Market for coke has bearing on West Virginia output. Latter likely to fall short of 1917. Whole situation beset with difficulty. Receipts by water quite irregular, and yet Washington wonders why coal is consigned all-rail to points adjacent to Tidewater. Anthracite deliveries continue to show falling-off as compared with a year ago. Large movement of steam sizes and a noticeable favoring of water shipments to Maine ports.

Bituminous—Notwithstanding the rosy reports that issue from Washington summarizing output all over the country, the regions from which New England draws the major part of its supply are steadily falling behind last year's marks. There have been days lately when car supply in central Pennsylvania showed real improvement, the proportion placed for general commercial purposes, including preferred industries, having risen to something over 50 per cent. It can no longer be urged that a New England "priority order" is chiefly to blame for the small tonnage available.

There is a new drive now upon the New River and Pocahontas agencies to get commitments on water coal. Those shippers who have not sold all the tonnage they are hoping to get are being besieged to take on new business. The line is very closely drawn, however, and those factors who own their own wharves and boat facilities have practically ceased making sales. Others who are partly or wholly dependent upon bottoms on trip-to-trip charters are careful not to undertake orders until the coal is definitely en route to the discharging point here. Instances multiply where industrial buyers are unable to make any arrangement either by rail or water, and to this small army of the "uncovered" should be added a large number of others who have contracts but are getting only small deliveries.

The volume of coal at the Virginia terminals continues quite uneven. Days there are when coal is not on hand to load boats, but generally speaking there are more instances of coal waiting for vessels than of vessels waiting for coal. Under the joint pool arrangement now in force a shipper having ample credits at one pier or another is permitted to draw from the supply at a pier other than where it would usually be furnished. This has led to misunderstanding among some of the coal people, especially when the present relative prices of Pocahontas and New River show a differential of 35c. The shortage of boats is still a great factor in making buyers consider seriously all suggestions for decreasing the quantities consumed. Not only did representatives of the Shipping Board scale down Mr. Storrow's estimate of the coastwise tonnage needed, but actual receipts of coal are far short of the smaller amount they fixed. At times a whole week goes by without a single cargo being available at Boston for distribution inland. Rehandlers who took contracts and made their estimates on the basis of steamers and barges then in hand are not getting coal in the volume expected, and there is much anxiety on the part of some of the largest steam users, who had reason to think their needs for the present at least would be comfortably supplied.

The first of the new lake-built 3000-ton steamers are now reaching here with cargoes of Cape Breton coal. This will help slightly, but not more than 100,000 tons can be counted on in this way; and this is really a much smaller tonnage when the quality of the coal is taken into account. The cargoes have been placed mainly with large plants at points adjacent to Searsport, Portland, Portsmouth and Boston, and probably in every case the coal will be turned in for immediate use.

The strong demand for coke has an important bearing on the output to be expected from the smokeless fields in West Virginia. Particularly is this true of Pocahontas operations, where years ago coke ovens were installed on a liberal scale for the purpose of increasing the car rating for individual mines. With the present authorized price of coke, to make a ton of which requires only 1.6 tons of slack, every ton of the latter so used will show the operator an extra profit of $2 per net ton over the fixed price for slack when shipped as commercial coal. The result is a big decrease in the volume of shipments from certain mines, a decrease which will spread to other operations sufficiently equipped with coke ovens. It almost seems as if this item should be given attention before too much tonnage is lost. While coke has got to be had for blast furnaces, yet it is easy to see how coke production in some districts can be overdone.

Another subject calling for prompt treatment at the hands of the fuel authorities is the order allowing a premium on coal "mechanically cleaned." The present regulation is much abused and a lot of unfairness results. Operators who need picking tables to make the coal merchantable are collecting the premium while others who have always been able to keep their output clean through rigid inspection and handpicking are denied the bonus. And both coals are pooled when shipped to tidewater!

Certainly the present state of the trade is alarming for New England. In no direction is there hope of adequate service. The areas ordinarily served almost wholly by water-borne coal would show shutdowns in considerable number were it not for the volume of coal coming all-rail that at present is just about enough to make up the shortage at tidewater for current consumption, but far behind what is needed to give a reserve for increased consumption and diminished receipts next fall and winter. And yet the regulating power in Washington continues to speculate just where an imaginary line should be drawn between an all-rail "zone" and a tidewater "zone." Surely if the central Pennsylvania district, for instance, is to cut down even the smaller quotas furnished for New England in 1915 and 1916 we have a hard time ahead of us.

A sign that the Fuel Administration means business is a recent circular sent through district representatives to operators and shippers. The latter are required to make shipments to industries on Preference List No. 1 and on requisitions issued from Washington or by the district representatives until such industries and individual plants that are on Preference List No. 1 are supplied with the necessary coal. Shipments going forward outside of the above classifications will be diverted and reconsigned.

Anthracite—While anthracite receipts all-rail are keeping up measurably well with the volume of the last three weeks, the showing is still unfavorable as compared with corresponding weeks in 1917. About 30 per cent. continues the proportion of steam sizes as compared with domestic. By water the tonnage shipped from Philadelphia and New York begins to show the result of instructions to favor eastern ports, particularly those on the Maine coast. While there is much pressure on retailers, the attitude of the latter is perhaps a shade more hopeful than a month ago.

Rates on certain anthracite-carrying barges from New York to Boston, and owned by anthracite shippers, were advanced May 11 from $1 to $1.50, making this rate the same as on anthracite in Reading barges from Philadelphia.

NEW YORK

Shipments of anthracite far below requirements, but dealers are optimistic. Sufficient orders booked to keep them busy for months to come. Appointment of Mr. Wiggin's successor urged by trade. Coal men and merchants confer. Trade urges retention of men in mines. Car supply improves in bituminous fields, but labor is short.

Anthracite—There has been practically no change in the movement of coal to this market, and while two months of the coal year are almost over and conditions serious, there is an optimistic feeling among most of the trade that there will be plenty of coal to go around between now and October.

The appointment of a successor to Albert H. Wiggin, who resigned as state fuel administrator a few weeks ago, is being urged by local coal men. Several names have been suggested, among them Reeve Schley, fuel administrator for New York County, Harry T. Peters, of Williams & Peters, who was chairman of the State Fuel Conservation Committee under Mr. Wiggin, and Wilber A. Marshall, of Marshall & Co.

Several conferences have taken place the past week, all looking toward securing for this city a sufficient supply of coal. One was a conference in the Chamber of Commerce attended by members of that organization's committee appointed to look into the coal situation, and several members of the trade, among whom was J. B. Dickson, of Dickson & Eddy, who is a member of the Anthracite Committee of the United States Fuel Administration.

Shipments during the week ended May 11 show a decrease of 2256 cars, or 5 per cent. over the preceding week. This decrease is reflected in the dumpings at this port for the week ended Monday, May 20, when 6346 cars were dumped as compared with 7546 cars for the week ended May 13.

With shipments prohibited to 24 states, it is expected that receipts here will gradually increase. However, until more bins are filled and the public is assured that there need be no anxiety regarding coal for next winter, dealers expect a steady demand.

Egg and stove are the sizes most wanted, and consequently the shortest in stock. Many householders use no other size and the result is that while dealers are able to deliver either chestnut or pea, they have none of the other larger sizes.

Buckwheat No. 1 is nearly as scarce as the larger coals, but rice and barley are easy with prices being held tight, except on some of the cheaper grades.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual
Broken	$6.15	$6.90
Egg	6.05	6.80
Stove	6.30	7.05
Chestnut	6.40	7.15
Pea	4.90	5.65
Buck	4.45@5.15	4.80@5.50
Rice	3.90@4.10	3.80@4.50
Barley	3.40@3.65	3.00@4.00
Boiler	3.65@3.90	.....

Bituminous—An improved car supply has not had an appreciable effect on local conditions. Demand continues far ahead of supply and the desire to get coal remains strong. Free coals are scarce at this port and what is to be had is said to be the inferior grades.

A serious condition exists in the bituminous mines with regard to labor. Workers are scarce, and even with the improvement in cars operators find it difficult to increase their output sufficiently to load the cars given them. It is fast becoming apparent that something must be done to induce the men to remain at the mines, otherwise operators believe the shortage next winter will be greater than it was last.

While production figures for the week ended May 11 show an increase of 252,000 tons, or 2.2 per cent. over the previous week, the dumpings at the local docks for the week ended May 20 were 6625 cars as compared with 6484 cars for the week ended May 13, an increase of 141 cars.

The local trade is eagerly awaiting a decision from Washington as to railroad fuel. Another month will see the termination of nearly all contracts for railroad coal, and the trade is desirous of knowing if the railroads will be permitted to get their fuel at prices below what the general public will be asked to pay.

Delay in shipping coal from the mines to tidewater is complained of by some shippers who handle good grades of bunker fuel. This delay, they say, in many instances causes them heavy losses owing to the failure of the railroads to forward cars promptly. When the coal does arrive it

may be that the vessel for which it is intended has already sailed, or is about to do so. Then it becomes necessary for the shipper to seek another customer while the coal may have been loaded into a barge, which results in additional costs to the shipper.

PHILADELPHIA

Anthracite shipments not up to expectations. Customers clamor for coal. Rail movement expedited by freight embargo. Domestic coal for manufacturing. Labor supply decreasing. Operators quizzed on shipments to utilities, etc. Steam coal all taken. Bituminous shows some improvement. Cars still short. Some stocking by plants. Coke price increase rumored.

Anthracite—With the big companies making heavy consignments to New England, the Philadelphia trade is naturally being neglected for the present. During April the market received close to its full quota or one-twelfth of its proportion, based on the 1916-17 receipts. The dealers fully expected as much or more this month, but judging from the present outlook the tonnage will run behind locally. The shippers, especially the larger ones, appear strong in their determination not to exceed their allotment in any case, and for the present at least the dealers who receive that much are considered as having received fair treatment.

The embargoes on domestic freight which became effective the middle of the week it is believed will greatly aid in the delivery of coal after it leaves the mines. This will be a big relief, as for the past two months the notice of a shipment meant little to the dealer, as he had no idea when to expect the coal.

At a meeting this week of the anthracite distribution committee and those most interested in that work, including a representative from Dr. Garfield's office, it was learned that while early in the season it was proposed to ship no domestic sizes of coal to manufacturing plants, it has already become necessary to make exceptions to this to the extent of over 2,000,000 tons for war work. The allotment for cantonments is also sure to be enormous and probably much larger than at first considered necessary.

It has been proposed to ship New England's quota for twelve months during the next nine months. This would mean a repetition of the plan suggested last winter, when because of this city's proximity to the mines it was presumed this market could be cared for almost overnight. It may be that the expected increase in the railroads' equipment, both in cars and engines, would by that time prevent a repetition of last winter's troubles, or at least lessen the severity. It must be said that those close to the situation here profess little optimism as to the future and can see only a season of discontent ahead.

All shippers of anthracite have recently received a communication from the Fuel Administration at Washington in reference to shipments to public utilities and certain essential manufacturing industries. The operators are directed to furnish a list of orders of commitments made with any gas company, manufacturing plant or public utility for the year from Apr. 1, 1918, as well as a similar list giving shipments as made in the year from Apr. 1, 1916. With the latter a list of plants is given and to these concerns the operators are directed to continue shipments without fail.

Gradually new freight tariffs covering anthracite coal are reaching the shipping offices. Practically most points outside of the state are now covered and recently tariffs have been coming in showing increases to nearby points. These increases are in accordance with the ruling of the Interstate Commerce Commission some months ago granting a raise of 15c. a ton. It was thought by some that this increase would not affect the rates within the State of Pennsylvania, but they are now becoming awake to the fact that the above commission has the power to make a general increase in rates regardless of the various state commissions. Up to this time the rates to points in strictly Philadelphia territory have not been increased, but there is no doubt that these tariffs will be received in a very short time. The first notice that many dealers had of the new rates was when they received their freight bills from the railroad company. Of course, all this adds to the retail price of the coal, and it is somewhat difficult to convince the consumer at times that the increasing cost of coal is justified.

In the steam-coal trade there is very little free coal to be had and every car of whatever size soon finds a buyer. It is noticeable throughout the city that heavy users of steam sizes are beginning to accumulate fair stocks of the small sizes, especially rice, and numerous vacant lots have been rented for this purpose and coal is rapidly pouring in.

The prices per gross ton f.o.b., cars for line shipments and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken.....	$4.90	$6.05	Buckwheat..	$3.15	$3.75
Egg.....	4.50	5.70	Rice.....	2.65	3.65
Stove.....	4.75	6.05	Boiler.....	2.45	3.55
Nut.....	4.85	6.10	Barley.....	2.15	2.40
Pea.....	3.45	4.35	.....		

Bituminous—It is difficult to give an accurate statement as to the soft coal trade. Of course, the operators still continue to cry for more cars. We are inclined, however, after a careful canvass of a number of shippers, to the opinion that conditions are improving. Of course, in a way, this is more or less of a general statement and is predicated a good deal upon the quantity of coal one sees upon the tracks these days. Utility plants in particular seem to be faring quite well just now and are putting away good stocks of fuel in excess of their immediate requirements. Quite a good bit of coal is being received in box cars, which would indicate that shipments in this district from wagon mines are growing, as the other mines are not allowed to load box cars in this direction.

BALTIMORE

Bituminous supplies here fairly easy. Anthracite dealers complain of poor receipts, while official fueldom urges consumers to buy at once.

Bituminous—With official Washington undoubtedly fearing a serious coal famine the coming winter, and issuing statements apparently intended to prepare the public for trouble ahead, Baltimore and the surrounding district for the time being is in fairly good supply of soft coal. Diversions here to clear railroad congestion at Cumberland and other points west brought the first element of relief to a rather strained situation, and since that time there has been enough natural flow at tide for all lines to enable a pretty fair distribution to industries here. There is no extra supply of coal on hand. Few industries have any stocks ahead of the time when the next shipments should be due.

Anthracite—All the hard coal dealers here are complaining of poor receipts. Official Washington is urging consumers to order early and insist on early deliveries, and this is being backed by the fuel administrator here. One prominent dealer here said he had more business on his books already than he could possibly supply by October, and that it was useless for him to book more at this time as he could not promise the coal. Many persons have appealed to the Baltimore Coal Exchange, saying they can not get promise of deliveries from dealers. All are being told to place their orders and wait their turn; that their dealers will deliver two-thirds of their orders as soon as they can get the coal. Small dealers especially have been hit by light arrivals recently, and their customers have been the most clamorous for relief.

Lake Markets

PITTSBURGH

Record production in district. Car shortage not serious. Open market for coal.

The Pittsburgh district shared fully in the rise in production reported by the Geological Survey for the week ended May 11, the record week for the country thus far, and conditions since then have improved a trifle more. The Pittsburgh district is easily shipping more coal than ever before in its history. A considerable contribution is made by the river mines, which are getting out a large tonnage, but the railroad mines are also doing well.

Car shortages averaging 15 to 20 per cent. are reported, but the trade is not disposed to regard it that production is actually restricted by this amount by car shortage, for while the supplies run under ratings by that amount it is far from clear that the mines would be able to load cars equal to their ratings in all cases. Indeed, some operators frankly admit that they could not load any more cars than they are receiving, though in most cases they attribute the difficulty to labor shortage.

There is now a fairly open market for Pittsburgh coal, there being a moderately large tonnage of free coal offered openly. As a rule this is taken up by brokers, who are doing a satisfactory business. Their turnover is not so large as it was a year ago, their margin per ton is somewhat less, and there is more work involved in putting through transactions; still the comparison with pre-war conditions is extremely favorable. In the case of Pittsburgh coal there is practically none offered at below the set prices, even to jobbers, and the jobber obtains only the 15c. allowed him, and receives it from the ultimate buyer. In the case of Ohio coal there are occasional offerings at less than the set prices, but not to such an extent that the broker could make more than 15c. a ton, as to do so he would have to buy at more than 15c. below the set price and sell at a correspondingly higher figure.

An open market is quotable at the set maximum prices, $2.20 for slack, $2.45 for mine-run and $2.70 for screened coal, plus 15c. in the case of coal sold by brokers.

BUFFALO

Receipts of bituminous slowing up. Still too much of it in Canada. Eastern embargoes hold up movements badly. Anthracite normal by Lake. More wanted locally.

Bituminous—It is generally held that the production is not much in excess of consumption, if it is equal to it, and yet jobbers find that consumers are holding off as soon as they get a moderate supply. It is again reported that Canada is pretty full of coal. Shippers have paid so much demurrage that they are more cautious, but they still manage to get a big supply across, mostly because they cannot sell it readily here. Locally the situation is easy. Consumers can get what they want without much difficulty.

The Government prices of bituminous continue without evasion, so far as can be observed, being $4.45 for all sizes of thin-vein Allegheny Valley, $4.25 for Pittsburgh lump, $4 for Pittsburgh mine-run and $3.75 for Pittsburgh slack, all per net ton, f.o.b. Buffalo.

Anthracite—The main new feature of this branch of the trade is that lake shipments have again gone above the 100,000-ton mark, where the movement ought to stay till the upper lake ports get as much as they need. All of our water shippers who are commonly active through the season are now loading vessels, and they will no doubt go on as usual. There are several occasional shippers, but they did little or nothing last season and they may not enter that branch of the trade now. It will all depend on the amount of coal they get out and how heavy the eastern demand turns out to be.

The local demand continues heavy, so that the authorities have to parcel out the coal in small lots as it comes in. Some of the more calculating people think it would be better to give everybody a full winter's supply as fast as possible and take them off the list. As it is now, with only a partial supply distributed everybody is trying to get more. The size is nearly all chestnut. How big furnaces are to burn it is not explained.

Lake shipments for the week were 101,500 net tons, of which 44,050 tons cleared for Chicago, 29,100 tons for Duluth and Superior, 3700 tons for Hubbell, 3500 tons for Green Bay, 3200 tons for Lake Linden, 14,300 tons for Milwaukee, 2200 tons for Sheboygan and 550 tons for Marinette. Rates were $1 to Marinette, 60 and 65c. to Chicago, 55c. to Milwaukee, 50c. to Sheboygan and Green Bay, 48c. to Duluth, 45c. to Hubbell and Lake Linden.

DETROIT

With steam coal supply fairly plentiful there is a deficiency of domestic, both bituminous and anthracite. Lake shipments diminish.

Bituminous—There is a comparatively free movement of steam coal into Detroit, according to local jobbers, who qualify this statement with the explanation that the larger part of the coal of this description received here is mine-run. Nut, pea and slack sizes are included in the receipts, but in each case the quantity is small. This is especially so as regards slack. The expectation that slack would be provided in larger amount with the opening of navigation on the lakes is not being fully realized.

There is a marked deficiency in supply of domestic sizes of bituminous. Whether this is the result of shipments of such coal to ports at the head of the lakes is not quite clear. Retail dealers complain they are experiencing considerable difficulty in covering their requirements for lump, suitable for household use.

Anthracite—No improvement in supply of anthracite has developed during the week. Shipments received by dealers are small and wholly inadequate for filling orders from customers. Practically none of the retail yards have more than a few tons on hand and most of them are declining to accept orders for later delivery.

Lake Trade—Instead of increasing in volume the lake movement of coal appears to be shrinking. About 100,000 tons a day is the average loading and the bulk of the traffic is handled by contract carriers. Small freighters, operating without contract, find cargoes difficult to find. One result is that many ships are making the upbound trip without cargo.

COLUMBUS

Activity in mining is gradually increasing with a better car supply. Demand is strong all along the line.

The coal trade in Ohio has continued strong and active in every way during the past week. Production was larger than in former weeks, and the movement generally was good. Retail demand continues strong and the same is true of steam sizes. The lake trade is gradually increasing. With a continuation of the better car supply it is believed that production will be kept at a high level. Prospects are for continued activity in every department of the trade.

The retail trade is now attracting considerable attention from producers and distributors. While the lake trade is taking a considerable tonnage from the retail trade, still a large tonnage is going to retailers. Dealers are anxious to accumulate stocks in order to take care of the heavy retail demand. Consumers are heeding the campaign on the part of the Fuel Administration to buy now for next winter, and consequently dealers are busy. Consumers are not waiting for the fancy grades but are taking any variety available. It is reported that little Pocahontas is expected to arrive in this territory. West Virginia splints are coming in better, but the amount is not so large as in previous years.

Steam business is active, as larger users are again trying to stock up to guard against a shortage if an increased tonnage goes to the Northwest. The smaller users are also showing a disposition to stock up. Consequently all steam grades are quickly snatched up, and there is no surplus mine-run on the market. Railroads are taking a larger tonnage.

The lake trade is active and all lake shippers are rushing a large tonnage to the lower lake ports. Loading machinery is busy and vessels are moving smoothly. The ore movement is increasing also under the influence of a better coal movement. Practically all lake shippers have now received their permits and are ready to go ahead in earnest.

The output in Ohio districts is increasing to a nice extent. This is especiallly true of the Hocking Valley section, which is producing about 90 per cent. of the average. In the Pomeroy Bend district the output is also large, and the same is true of Crooksville and Cambridge. In eastern Ohio the car supply is better, but there is still a serious shortage and the output is estimated at 80 per cent.

CINCINNATI

Maximum activity prevails in connection with supplying storage demand and forwarding coal to Lakes, this movement being very heavy.

With a good car supply and a correspondingly increased production, there is still hardly enough coal coming forward to take care of all the demand which now exists, since the movement to the Lakes for forwarding to Northwestern ports has reached a good volume. The usual situation, in which virtually all of the coal passing through this point during the late spring and early summer months was permitted to go onto the Lakes, does not now exist, as the demand for coal for storage by local consumers, both industrial and domestic, is sufficiently large to take care of all the available fuel for some time to come. However, the trade is taking its time in the matter of supplying this demand, and while deliveries for storage are increasing in volume, it is felt that as there are several months in which to satisfy the requirements of consumers for storage there is no cause to worry. Whether there will be difficulty in future in making up the deficit which now exists in the matter of production as compared with total requirements is another matter. Distributors feel that they are handling the situation now as well as possible, and that if the volume of coal moved forward from the mines can be increased as the season advances there will be no difficulty in caring for the demand from all quarters.

LOUISVILLE

All coal a little long, with exception of domestic. Steady demand for domestic for stocking purposes, with retailers unable to secure surplus yard stocks.

The general demand for all grades of coal is fair at this time, but steam coal has not been so active as domestic coal, which is moving much better than ever known at this time of year. However, operators are having no difficulty in disposing of mine production.

In the eastern Kentucky district the car supply has improved materially, and mines are now getting about 80 per cent. of their car requirements. However, the mines are not able to operate more than 50 per cent. full time, due to the shortage of labor, which is being intensified by the draft and the agricultural demand. The use of farm tractors has relieved the agricultural demand to some extent, but with improved weather conditions many men have deserted the mines for work in the open fields.

BIRMINGHAM

Domestic and steam coal demand active. Heavy tonnage required by the railroads menaces supply for industrial plants. Brokers besieged with orders which they are unable to handle. Production badly off, which makes the situation more tense.

The shortage of coal to supply the demands on the local market is the most serious factor in the situation here—which applies to both the domestic and steam product.

Domestic dealers are clamoring for shipments and are only getting about half the tonnage they desire, which is being promptly distributed to their customers, in some instances being loaded direct from the cars into the wagons. All sections of the zone are making insistent requests for coal, and the output of the domestic mines is being prorated over the whole territory. However, one reassuring feature is that every consumer that possibly can do so is laying in coal for next season's use. Dealers cannot see far ahead in respect to the amount of coal they are to receive from the mines, as few contracts have been made, shipments being made principally on verbal understandings covering a limited period.

All rail lines in this district are drawing heavily on the coal supply, particularly the Southern and Louisville & Nashville, claiming the full tonnage taken is used in current operations, no effort at stocking being made. The Southern's quota is 46.84 per cent. of the output of the mines on its lines, aside from operations of furnace companies and strictly domestic producers. During the past week cotton factories, which are quite numerous in this zone, were added to the priority list. Brick plants and other less essential operations are receiving a restricted supply.

Coal production is not satisfactory, complaint being general that miners and mine workers are showing a disregard for regularity at work, which is seriously curtailing the output. Increased wage schedules, as in the past, have not proved a panacea for this ill.

Coke

CONNELLSVILLE

Slightly increased shipments. Less complaint of car shortage. More Connellsville coal to be shipped. Iron industry fairly well supplied. Little coke surplus for open market offerings.

There has been only a slight increase in the shipments of Connellsville coke, but there has been a larger increase in the shipment of Connellsville coal, partly against new byproduct coking operations about to begin operations. While there remains much complaint as to car shortage, there is less than there was, and there is more complaint about labor shortage, particularly along the line that now that the men are offered more steady work they take more days off, as they can spare the money. Two or three months ago men were hanging around the works in hopes that cars might come in and give them work, while now some of them do not report when work is assured.

On the whole coke conditions are rather satisfactory as compared with conditions up to a few weeks ago. This is reflected in the operation of blast furnaces, as practically all the furnaces in blast are receiving adequate supplies and are operating at capacity, the only curtailment in pig-iron production being through a few furnaces remaining out of blast waiting for coke to accumulate.

It has become fairly clear that Connellsville coke production is unlikely to increase materially over the rate of the past few weeks, say 325,000 to 350,000 tons a week, but there will be increases in the coal shipped to byproduct operations. The production of coke in the United States in the ten weeks ended May 11 was at the rate of 10 per cent. above the rate in 1916, while the present blast furnace capacity is only between 10 and 15 per cent. in excess of the actual pig-iron production in 1916, from which it follows that with a slight further increase in coke production, with the diversion of as large a proportion of the coke to blast furnaces as formerly, which of course is to be expected, and with coke of as good quality as formerly, the iron and steel industry should be fully supplied with coke.

Shipments continue to be rather fully taken up by contracts, but some furnaces are reaching a point where they are disposed to have shipments under contract curtailed somewhat, and in the course of time this may result in general offerings in the open market. At present such offerings are rather exceptional. The market is quotable at the set maximum prices: Furnace, $6; foundry, 72-hour selected, $7; crushed, over 1-in., $7.30, per net ton at ovens.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended May 11 at 341,110 tons, an increase of 7655 tons.

Buffalo—The supply is light and is obtained mostly from the ovens direct. If any is controlled by jobbers here it goes to Canada, where a commission is allowed. In fact the trade is not restricted there, so the supply is rather good. Shippers say that quite an amount of coke-ash siftings is coming this way. It is fit for nothing but to mix with coal for making steam. It is sometimes so low in value that it has to be sold to the railroads at very little more than the freight. Furnaces are running actively and ore is coming in freely by lake.

Birmingham—Coke market conditions are ideal so far as the demand for the product goes, but the supply during the past week or so has been crippled by labor shortage and other operating disabilities. One of the larger foundry-coke producers reported his output about 40 per cent. off; others much under normal. Transportation facilities are now good and ample cars are being furnished for both district and foreign use.

Middle Western

GENERAL REVIEW

Car supply shows some improvement, but miners fail to respond to their opportunities.

In most sections of the Middle West there was an improvement in the supply of equipment during the past week, but miners failed to avail themselves of the opportunity to increase production. Semi-monthly pay day occurred on Wednesday the 15th, and the fact that the miners are now making more money than ever before causes many of them to support the saloon without regard to the country's needs for higher efficiency in coal production. The immediate stopping of the sale of intoxicants would measurably increase coal production, and also render a beneficial service to both the miners and their families, reduce accidents to the lowest possible unit, and redound to the good of the public generally.

Market conditions continue to be satisfactory on all grades with the exception of No. 5 and screenings. These two grades are giving sales managers some worry. This is particularly true of the central and northern Illinois group as well as of Indiana. Prices continue to remain on a level with established maximums. In some instances, it has been noticed that the producer was compelled to give the jobber 10 and 15c. per ton margin in order to move screenings and No. 5. This margin was not reflected in any reduction to the ultimate user, the only difference being that the Government pit mouth price was paid to the jobber instead of to the operator. Such sales were limited and had little effect on general market conditions.

The railroads are not buying in excess of their immediate needs, and the movement of prepared coal to the householder continues to be gratifying. Mines in Franklin, Saline, Williamson, Perry, Jackson and many other Illinois counties, as well as a large number of Indiana operations, have sufficient orders ahead for size coal to keep them going for some time to come. Retail dealers everywhere are unable to accumulate any storage stock and are able to unload from the car and haul direct to the customers' basement all the coal they can get.

CHICAGO

Conditions indicate some improvement. Screenings troublesome in some cases.

In many respects the coal market shows some improvement over conditions 30 days ago. The unusual demand makes all efforts to supply size-coal orders seem insignificant. The buyers seem willing to absorb everything in sight and indicate their willingness to place orders for months in advance. On the other hand, producing companies hesitate to load themselves with contracts for any grade other than fine coal, which grade they are compelled to make if they are able to supply the trade with lump, egg and nut. Operators contend they may be compelled to load railroad mine-run in order to protect their operation against an accumulation of no-billed cars of fine coal, unless there is a heavier buying of the latter grade. Although a slightly better average can be maintained by separating and selling at Government prices, no operator is willing to accept large orders for size coal unless he has fine coal contracts enough to take all his screenings.

The movement of anthracite showed some improvement during the past week but is still short of expectations.

Quotations in the Chicago market are as follows, per net ton f. o. b. cars at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Springfield	Carterville	Grundy, La. Salle, Bureau and Will
Steam lump	$2.65@2.80	$2.65@2.80	$3.05@3.20	$2.65@2.80	$2.65@2.80	$3.35@3.50

MILWAUKEE

Federal agents investigating the cost of handling coal over Milwaukee docks. Dealers holding back deliveries of hard coal until a price schedule is fixed. Receipts by Lake slow and not up to last year's record.

Six special agents of the Federal fuel administration office are in Milwaukee studying the cost of handling coal over the docks. Their findings will determine the price of coal to Milwaukee consumers. No attention will be given to the cost of transferring coal from cars.

State Fuel Administrator Fitzgerald admits that dealers are disinclined to make deliveries of hard coal until prices are fixed by the Government, but he urges consumers to place their orders promptly nevertheless, as deliveries will be pushed as soon as a scale of prices is promulgated. He also enjoins users of soft coal to put in supplies before the season of car shortage begins and to keep a 60-day stock on hand. He reports that Illinois producers are so swamped with orders that no deliveries are promised until six weeks after receipt of orders.

Coal cargoes are slow in arriving, and the record thus far is considerably behind that of last year, up to this time. Since last week's report 13 cargoes have been received at Milwaukee, amounting in all to 87,376 tons, of which 11,370 tons were anthracite. Cargo receipts up to and including May 20 aggregate 303,359 tons, of which 58,972 tons were anthracite.

The city of Eau Claire has abandoned its plan to establish a municipal fuel plant until after the war, because an issue of bonds to the amount of $10,000 would be necessary to carry out the project.

ST. LOUIS

A somewhat strenuous market on high-grade coals. A heavy demand with no supply to meet it. Standard market easier. Car supply short on many roads, and transportation unusually slow. No steam demand and railroad buying light.

There continues to be a demand for Carterville district coal that cannot be met, and operators are having orders forced on them that at the present time means some time in July before they will be shipped. A determined effort is being made by the Fuel Administration and dealers to prevail upon the public to buy the coals that are most available, but the demand for Carterville continues in spite of these efforts.

In the Carterville field cars are short and nearly all mines are showing a decreased tonnage on account of labor shortage. The railroads are falling down miserably in a general way on transportation. The Iron Mountain and the Illinois Central are especially bad, and in the St. Louis terminals conditions are beyond description.

Embargoes are on daily to certain parts of the city and surrounding territory on account of the congested manner in which coal and other freight is being handled in the terminals. The Fuel Administrator's office has been obliged several times in the past week to order embargoes against coal released.

Coal yards are without coal for as long as three or four days, and then have enough coal put in on one switch to last for almost a week. In the Duquoin field conditions are somewhat similar to those in the Carterville field.

Mt. Olive district presents normal conditions at this time. The production, which is being pushed to the utmost, is just about equal to the demand, except on steam coal, which is dragging here, as everywhere else. Working conditions are good and the car supply is fair.

In the Standard fields the Mobile & Ohio is in bad shape for cars and the Illinois Central comes next. Transportation on most all the roads is extremely bad, excepting on the short lines. Labor conditions are not all that they might be, but it is because of a scarcity of men accounted for by the draft and by those who leave to take positions that pay better.

The Illinois Southern transfer at St. Genevieve, after being out of commission for the past few months, is again working, thus getting a supply of coal for the southeast Missouri lead mines, and is relieving the congestion at East St. Louis.

There is, however, a better tone to conditions in the Standard field, and just as soon as the railroads start to buy, which ought to be pretty soon, this is going to improve.

Domestic demand is as great as can be handled at this time, and yet there is an over-production of coal in the Standard field. Railroads should be taking this for storage, but they are not doing so. Later on, when the poor of the country must have coal, the railroads will come in and have it confiscated.

There is practically no anthracite coal coming in and very little Arkansas.

The circular here is, per net ton f.o.b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard

Williamson & Franklin Co. rate is 87½c.; other fields, 72½c.

General Statistics

BALTIMORE & OHIO

The following is a statement of coal and coke tonnage moved over the Baltimore & Ohio system and affiliated lines during the month of February, 1918, as compared with the corresponding month of the previous year:

	1918 Tons	1917 Tons
Coal	3,225,974	2,471,359
Coke	225,258	203,766
Total	3,451,232	2,675,125

APRIL SHIPMENTS OF ANTHRACITE

The shipments of anthracite in April, 1918, as reported to the Anthracite Bureau of Information, amounted to 6,368,372 tons, an increase of 776,074 tons, or almost 14 per cent. over those of the corresponding month of last year. Despite several record-breaking months during the coal year ending Mar. 31, and the remarkable showing for the entire year, the April, 1918, shipments are close to the high monthly average maintained during the year. The shipments by carrier companies in April 1917 and 1918, were as follows:

	April, 1918	April, 1917
P. & R. Ry	1,233,512	1,004,028
L. V. R.R.	1,175,027	988,873
C. R.R. of N. J.	649,621	626,501
D. L. & W. R.	1,008,018	893,458
D. & H. Co.	771,553	639,495
Penna. R.R.	448,374	433,314
Erie R.R.	695,186	664,609

COAL AGE

Volume 13 NEW YORK, JUNE 1, 1918 Number 22

Americanizing the Foreigner

PATRIOTISM is the oil that lubricates the machinery of victory. Lacking vision or ambition, we shall find ourselves unready to do our utmost at this time of the country's great need. We must be enabled to sense our citizenship, or we will not work hard enough and steady enough and live rigorously enough to buy a fair quota of Liberty Bonds and do our part for the Red Cross.

Flag Day, which will occur on June 14, offers us another opportunity to rededicate ourselves to the purposes that we recognize are noblest in our national life and to deepen the pure spirit of Americanism in the hearts of all Americans. It also gives us another occasion on which we can show to those who have come to this land from beyond the seas the aims that animate our hearts and regulate our lives.

But let us beware of some of the dangers of Flag Day. That day for the foreigner should be a time of welcome and not of reprobation. The foreigner will never be made a good citizen by condemnation of his friends across the ocean. The bitternesses aroused by unfavorable comparisons have done not a little to vex and disgust those who have come among us.

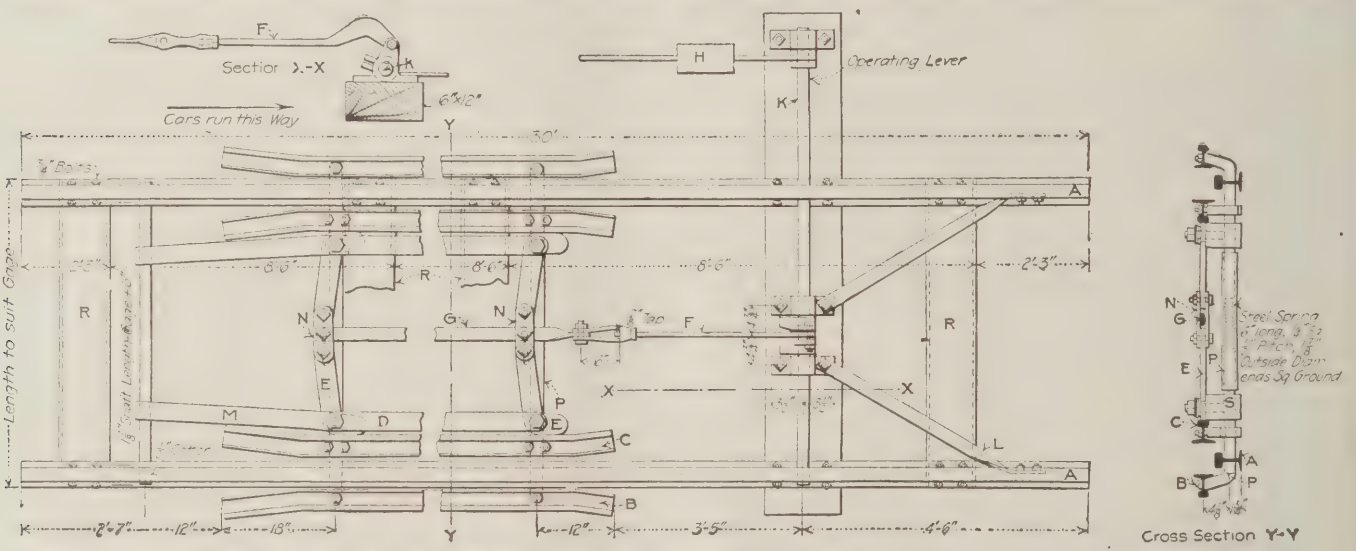
Only a little while ago our orators were repeatedly and unctuously thanking the Almighty that we, unlike the nations of Europe, were not engaged in slaughter. We are now, as we should have been from the first, fighting in the advocacy of Democracy and Justice. Let us not spend our time, therefore, in vain comparisons, which are always unfortunate and sometimes not fair. Worse than boasting is the disparagement of others.

We have much to be proud of and much to be grateful for. Let us congratulate ourselves on what we have. Let us not be like a certain large generality of people who can only get happiness out of the peace following a thunderstorm by rejoicing that some other man's barn was hit and not theirs. They cannot rejoice in a good crop unless they are able to say that some other man's field suffered from a drought. They find no points for admiration in their own trotter unless they can point to some poor cripple that it passed on the road.

It may be that the foreigner is the man of the stricken barn, the blighted field and the crippled horse, but no good will come of reminding him of his misfortunes. In the language of the street, "Have a heart." What a foreigner wants more than your praise of America or your denunciation of his fatherland or motherland is the grip of your hand, the tremor of your voice and the exaltation of service that your patriotism evokes.

Much Flag Day oratory is like the red flag waved in the eyes of a bull. It is utterly undiscerning and unsympathetic. "Come with us," should be the message of the day to the foreigner. "Come with us, and we together will make this America a new earth—a country full of sympathy and understanding, a land of domestic peace and helpfulness, a land of unity and good works. We have given an earnest in the past of our good will to all men. It is our purpose that in the future the measure of our intentions shall be no less inclusive and generous."

On Flag Day there will be some mines in the bituminous fields without opportunity to work. Let such mines hold an all-day celebration. Other plants in the same district, with the promise of cars for Flag Day, can make their commemoration after the day's work is finished.



The operator should not fail to give his fullest support to the national movement now being made for the proper observance of this important holiday. A celebration may cost him some money, but if he hesitates to give a little to the performance of this patriotic duty he is lacking in the spirit of a true American.

IDEAS AND SUGGESTIONS

Piatt Car Spragger

At certain points around collieries where trips of mine cars are handled, it is essential that the movement of a car or a trip of cars be checked within a car's length or even less. It is readily seen that, at the foot of car hoists or planes at breakers, for example, where loaded cars are feeding in continually, they must be controlled absolutely. It is rather unfortunate when a loaded trip piles up in the shaft bottom.

An official at the Franklin colliery of the Lehigh Valley Coal Co., near Wilkes-Barre, Penn., has worked out a scheme for spragging or retarding cars which is shown in detail in the accompanying illustration. It is known as the Piatt car spragger and is the invention of James Piatt, outside foreman at the Franklin colliery. It is installed at the foot of the car hoist of the Franklin breaker, among other applications, and was

CAR SPRAGGER IN USE AT FRANKLIN COLLIERY OF LEHIGH VALLEY COAL CO., NEAR WILKES-BARRE, PENN.

doing effective work at the time the writer saw it in operation.

By reference to the accompanying illustration, its method of operation may readily be seen. Briefly, the rims of car wheels are clamped in a vise at the rails on either side at the mine car by the simple throw of a lever. Its action is positive and entirely reliable. As to the details of the device: The mechanism of the retarder is attached to the track rails *A*, within a few feet of the bottom of the hoist. *B* and *C* are rails which constitute the clamp holding the rims of mine car wheels. These rails *B* and *C* have their base vertical and are so adjusted as to come in contact with the rims of wheels when thrown into engagement.

The outside clamp rails *B* are rigidly connected by the linking iron *P*. Their position relative to each other is capable of adjustment. Thus when the rails *C* are thrown into clamping position they move toward the rails *B*. If the space between the rails *B* and *C*, in clamping position, is not such as to hold the rims of wheels firmly, then this space is reduced. This is done by bringing the rails *B* closer together by the adjusting link *P*.

The movable rails *C* are operated by simple mechanism. At intervals along the rails *C*, on either side, are the cams *E*; the short arm of these cams engages the rails *C*. The other ends of the cams are connected by the yokes *N*, the reach rods *G* and the toggle iron *F* to the lever shaft *K*. The forward movement of the operating lever *H* on the shaft *K*, through the foregoing connections, produces a movement of the rails *C* toward the rails *B*. The pivot of the cams *E* is rigidly attached to the iron *P* by means of the irons *S*, which are shrunk on *P*.

The track rails *A* are tied together by the 8-in. channels *R*. The lever shaft is mounted on a 6 x 12-in. oak tie; and the toggles, with their operating mechanism, are held in position by the strap irons *M* and *D*. In the illustration the retarder is shown in "open position"—cars can now pass through. When the lever *H* is thrown forward (in the direction loaded cars run), the connecting-rods move the toggles, which force the rails *C* closer to the rails *B*. This vise-like action tends to clamp the rims of car wheels and stop their movement.

When the lever *H* is in its extreme forward position the toggle is on a "dead center," which tends to lock the mechanism in its clamping position. Under the conditions noted the lever *H* rests on the ground and is largely held in that position by the disk weight attached to it, as shown in the illustration. This retarder has the power to hold a trip of loaded cars. If little work is to be done, as is often the case when only a few cars feed in slowly, then ordinary sprags are frequently used. Sometimes sprags do not hold well in wet weather when the rails are slippery. In such cases, and when a long trip gains momentum, then the Piatt spragger comes to the rescue and will do the work well.

Makeshift Rail Bender

By J. A. Smith
Albert, W. Va.

Mr. Dalton's article in *Coal Age* of Apr. 27 brought to mind a makeshift rail bender used in mines where the thickness of the coal bed is less than 6 ft. In many mines using 12 to 16 lb. steel rail in rooms the trackman lays the switch at the foot of the room, after which the miner is required to lay his track and any "turns" necessary. As soon as the first crosscut is driven far enough in to require a turn, if no rail bender is available the miner curves a turn as follows:

He cuts a prop a few inches shorter than the height of seam and then marks the rails at points where curves are to begin. The prop is set vertically and the rail laid between the top of the prop and the roof, with the end of the rail extending through until the point where the curve starts is just over the prop. By bearing down on the long end the rail is bent without difficulty. Rail is then pushed through 12 in. or thereabout and again bent. This is continued until only 4 ft. remains uncurved.

The rail is now spiked in place and the final 4 ft. is curved by slipping a pipe sleeve over the rail and inserting a claw bar therein, when sufficient leverage is obtained to bend the rail to within 12 in. of the end. Both rails of a turn can be curved in 15 min., or less time than it takes to procure a regular bender. The sleeve mentioned is also useful in straightening a rail which is bent close to the end.

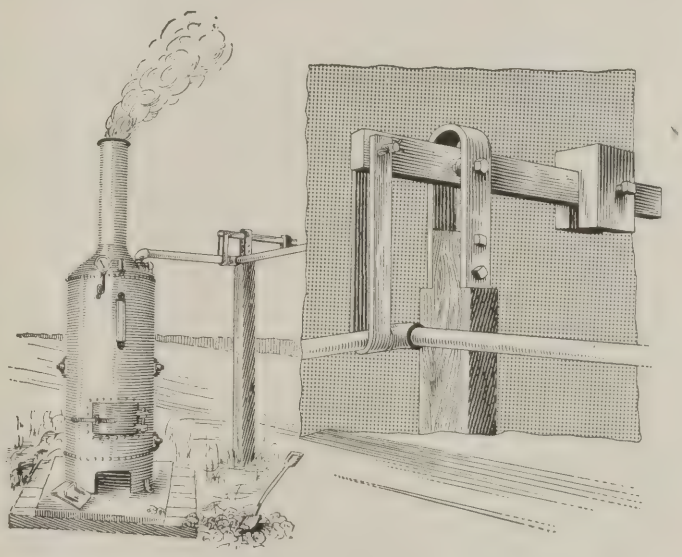
Precautions in the Use of Gasoline

In order to minimize the risk of fires, observe these precautions:

1. Keep open lights away from all gasoline cans or tanks, feed pipes, and engines.
2. Use only closed cans or tanks for carrying gasoline into the mine.
3. Use only a closed can, like an oil can, for priming with gasoline, and keep the can where it cannot be knocked over.
4. Never store more than five gallons of gasoline or as much more as is required for one day's work in the mine.
5. Do not let oily waste or rags lie in the engine room. Put them in a metal pail. Use sand to absorb oil drippings.
6. Never use water to extinguish a gasoline fire. Always use a chemical fire extinguisher or smother the fire with sand. Keep a supply of sand in the engine room and the storage room.
7. Use as little wood as possible for fittings in engine room. Where possible cover wooden posts, etc., with asbestos board.

To minimize the danger of explosions:

1. Have the engine room and the storeroom well ventilated.
2. Never let gasoline stand in open cans or tanks.
3. Do not pour gasoline from one container into another near open lights.
4. Do not spill gasoline.
5. Do not use gasoline for cleaning in a closed room.
6. Unless all the openings of empty cans or barrels are closed, always store them with the openings down so that the vapors may escape.



To minimize the danger from the exhaust gases of a gasoline engine:

1. Set the carburetor, or mixing valve, to give as lean a mixture as will run the engine.
2. Pipe the exhaust gases out of the engine room.
3. Do not work or even stand near the end of the exhaust pipe when the engine is running.
4. Do not try to purify the exhaust by turning it under water.
5. Unless the ventilation in the place where the engine is used is ample and positive, pipe the exhaust gases to some point where there is such ventilation, or pipe them to the surface.—*Technical Paper, No. 174, U. S. Bureau of Mines.*

Unique Expansion Joint

By L. V. Lauther
Guttenberg, N. J.

The vertical boiler of an 8-hp. hoisting engine expanded nearly ¾ in. when the fire was started in the cold boiler in the morning. Owing to the climatic conditions, the fire was permitted to go out every night and

GENERAL VIEW AND DETAIL OF PIPE SUPPORT

the water also was blown off. No outside insulation was provided on the entire outfit. The repeated expansion and contraction soon exerted an injurious influence on the pipe joints. The latter became loose and steam began to leak from the pipe line from almost every joint. The prospector, either because he was not familiar with power-plant equipment, or was adverse to incurring extra expense, rigged up an ingenious device which tided him over his difficulty.

This outfit, shown in the accompanying illustration, possessed the advantage that it not only provided for expansion, but also took the weight in such a manner that it was always in right proportion to the height of the boiler.

Of course, the right position for the counterweight was found by experiment. The pivot was well greased with graphite. The drawing is sufficiently clear to make the device comprehensive to anyone dealing with this kind of steam boiler.

Centrifugal Mine Pumps

By OTTO HAENTJENS
Hazleton, Penn.

WITH the increasing number of centrifugal pump installations in mines, a thorough knowledge of the principles of theory and design of these machines becomes necessary. Centrifugal pumps vary in many ways from direct-acting pumps and are a puzzle to men not familiar with their construction and their sometimes peculiar behavior. Really they are quite simple machines, consisting only of a few parts.

Although the theory of these pumps is complicated, it can be reduced to one simple formula, from which can be derived the principal laws that govern the construction and operation of centrifugal pumps. As this article is written not for the designer but mainly for the mining engineer it is not necessary to show how this formula was derived and lengthy theoretical discussion is omitted.

PRESSURE in a centrifugal pump is produced by centrifugal force and by transforming velocity into pressure. The peripheral speed of the impeller determines the centrifugal force and the outlet opening

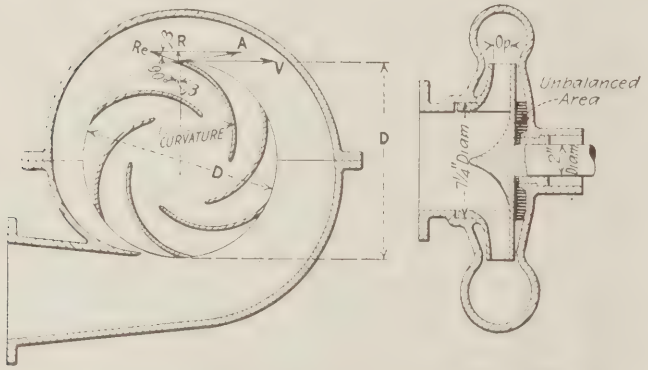


FIG. 1. OUTLINE AND FORCE DIAGRAM OF A CENTRIFUGAL PUMP

of the impeller and the curvature of the blade determine the absolute velocity to be transformed into pressure. Referring to Fig. 1:

D = Impeller diameter, in inches;

O_p = Impeller opening, in inches;

V = Peripheral velocity of impeller, in ft. per sec. $= \frac{D}{229} \times$ r.p.m.;

R = Radial velocity, in ft. per sec. $= \frac{\text{G.p.m.}}{3.12 \times \pi \times D \times O_p}$;

R_e = Relative velocity along the blades $= \frac{R}{\sin \beta}$;

A = Absolute velocity at which the water is discharged from the impeller, in ft. per sec. $= \sqrt{R^2 + X^2}$;

β = Blade angle.

The theoretical head H which a centrifugal pump develops is

$$H = \frac{V \times \left(V - \frac{R}{tg\ \beta}\right)}{g}$$

or

$$H = \frac{V \times X}{32} \quad \text{(See Fig. 2)}$$

The theoretical horsepower required to raise 1 gal. of water H feet high per minute is

$$Hp. = \frac{1}{3960} \times H$$

Doubling the speed of the pump doubles R (see Fig. 3) and therefore the capacity, as R is a direct function of the capacity. Doubling the speed also doubles X, and the head H therefore increases to:

$$\frac{2V \times 2X}{32} = 4 \times \frac{V \times X}{32} = 4 \times H$$

Doubling the speed increases the horsepower to:

$$2 \times \frac{1}{3960} \times 4 \times \frac{V \times X}{32} = 8 \times \frac{1}{3960} \times H$$

If a centrifugal pump, running at 1200 r.p.m. and delivering 1000 g.p.m. against a 100-ft. head and requiring 50 hp. be speeded up to 2400 r.p.m., the capacity would increase to $2 \times 1000 = 2000$ g.p.m., the head to $4 \times 100 = 400$ ft., and the horsepower to $8 \times 50 = 400$ hp., or, generally speaking, *if the speed of a centrifugal pump is changed, the capacity changes in direct proportion to the speed, the head as the square and the horsepower as the cube of the speed.*

If the speed of a centrifugal pump is kept constant, but the capacity is reduced or increased by throttling or opening the discharge valve, R changes in direct proportion to the capacity. As R decreases, X increases and therefore the head produced by the pump will increase. If the discharge valve is shut entirely so that no water can be discharged, R becomes zero and $X = V$ and $H = \frac{V \times V}{32} = \frac{V^2}{32}$ (zero capacity, maximum head).

If the discharge valve is fully opened, R becomes a

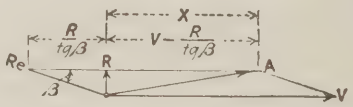

FIG. 2

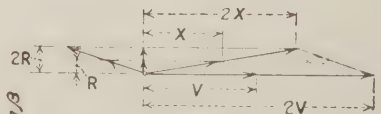

FIG. 3

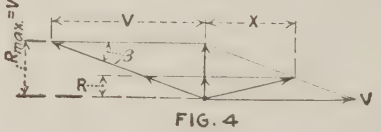

FIG. 4

FIGS. 2, 3 AND 4. VARIOUS PUMP DIAGRAMS

maximum $= V \times tg\ \beta$ (see Fig. 4) and X becomes zero and the pump would theoretically produce a head

$$H = \frac{V \times O}{32} = 0 \quad \text{(maximum capacity zero head)}$$

The maximum theoretical capacity is:

$V \times tg\beta \times 3.12 \times \pi \times D \times O_p$ *gal. per min.*

Having determined the maximum head and the maximum capacity, in plotting these points on cross-section paper (see Fig. 5) all intermediate points must fall

on a straight line connecting these two. This line may then be called the theoretical head-capacity line.

The horsepower curve corresponding to this head-capacity line can easily be figured and represents a parabola, as shown in Fig. 5.

The curves known as characteristic curves indicate the head developed at different deliveries (head-capac-

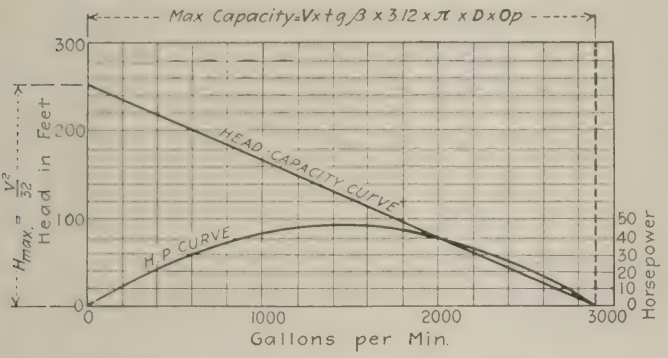

FIG. 5. THE HEAD-CAPACITY AND HORSEPOWER CURVES OF A PUMP

ity curve), the horsepower required to drive the pump at different deliveries (horsepower curve), and the efficiency developed by the pump at different deliveries (efficiency curve). They are obtained by testing the pump at constant speed on the factory test stand. The actual head-capacity curve differs considerably from the theoretical head-capacity line, but the inclination of the theoretical line influences the shape of the actual head-capacity curve and the horsepower curve to such an extent that theoretical head-capacity lines can be used for comparing the characteristics of various impellers.

Fig. 6 shows the diagram of a 6-in. pump impeller and Fig. 7 shows the theoretical head-capacity line, the actual head-capacity curve and the efficiency curve of this impeller. The best efficiency coincides with the "condition point," that is the conditions for which the pump was intended—namely, 1000 g.p.m. against a 100-ft. head. Although this is desirable, it will in practice not always be the case, especially with volute pumps.

Manufacturers sell a pump for any condition within certain economical limits, as shown in Fig. 7, in order to reduce the number of patterns for casings and impellers. It is the aim of the designer to produce a pump that gives good efficiency over a wide range—that is, large economical limits.

It will be seen from Fig. 7 that at the condition point the actual head obtained is only 60 per cent. of the theoretical head; or, in other words, the hydraulic efficiency is 60 per cent. The hydraulic efficiency varies with the delivery and usually reaches a maximum, a little ahead of the best efficiency point (in Fig. 7 at 900 g.p.m.). Shock losses and leakage within the pump determine the magnitude of the hydraulic efficiency, but the hydraulic efficiency of a centrifugal pump does not directly affect the mechanical efficiency. A centrifugal pump may have an hydraulic efficiency of 60 per cent. and yet have a mechanical efficiency of 70 per cent. or over. The hydraulic efficiency at the condition point varies between 55 and 75 per cent., depending on the size and type of the pump. At shut-off, the hydraulic efficiency varies between 45 and 55 per cent., depending on the impeller dimensions. It is usually around 50 per cent.

Effect of Vane Angle on Head-Capacity and Horsepower Curves

The blade angle of the impeller, whose velocity diagram is shown in Fig. 6, was 18 deg. If this angle is changed to 35 deg., X increases to 75.7 (see Fig. 8). Assuming an hydraulic efficiency of 60 per cent. as before, the actual head produced by this impeller would be $0.6 \times \frac{75.7 \times 90}{32} = 127.5$ ft. In order to produce only 100 ft. head with this 35-deg. impeller, the peripheral velocity must be reduced to 80.5 ft. In Fig. 9 are shown the theoretical head-capacity lines with their corresponding horsepower curves and the actual head-capacity curves of the two impellers.

It will be noted that: (1) A steep angle gives a low shut-off pressure, one that may be considerably below the condition point. This may make it impossible to start a pump when the column pipe is filled, as the shut-off pressure is not sufficient to open the check valve in the column pipe. In order to start such a pump a certain amount of water must first be bypassed, so that the pressure can build up. (2) A flat angle produces a steep head-capacity curve. If the pump draws water from a sump whose level changes (as is usually the case), the suction lift gradually increases. Assuming that the level changes 10 ft., this would increase the total head against which the pump has to work to 100 ft. The capacity of the 18-deg. impeller

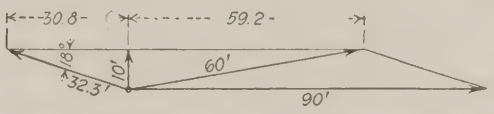

FIG. 6. DIAGRAM OF A 6-IN. IMPELLER

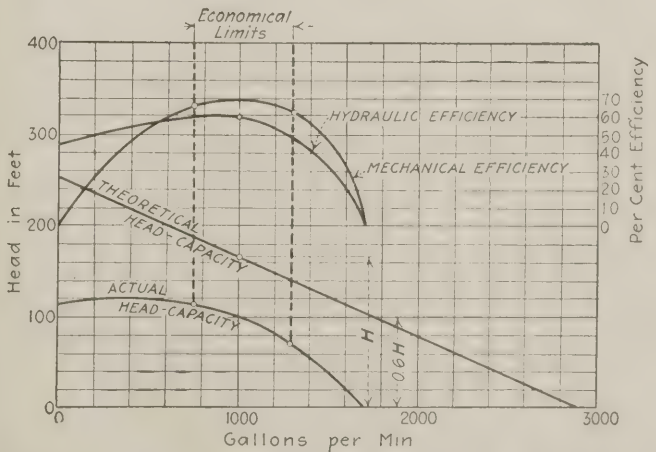

FIG. 7. CHARACTERISTIC CURVES OF 6-IN. IMPELLER

would be reduced to 800 g.p.m., whereas the 35-deg. impeller would cease to deliver water, as the maximum head which this impeller produces is 106 feet. (3) The horsepower curve, produced by the 18-deg. impeller, is flat and reaches a maximum near the condition point; whereas the corresponding curve, of the 35-deg. impeller, continues to climb after the condition point is passed. Should the head on the pump be diminished as through a break in the pipe line or when starting the pump with

the column pipe empty, the 18-deg. impeller would only slightly overload the motor, whereas the 35-deg. impeller would seriously overload it. Preference should therefore be given to impellers with small angles—that is, with strongly backward curved vanes.

Referring to Fig. 1, A represents the velocity and direction of the water as it leaves the impeller. This must be reduced and converted into pressure. Taking as an example the velocity diagram of the 6-in. pump shown in Fig. 6, the absolute velocity A is 60 ft. per sec. This velocity must be reduced to that in the 6-in. discharge pipe—that is, to 11.5 ft. per sec.—and this must be done gradually and with the least possible shock,

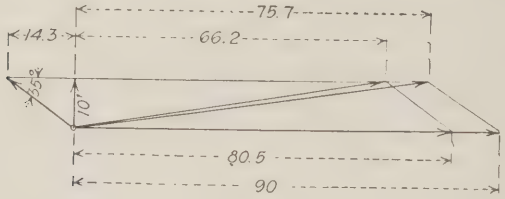

FIG. 8. EFFECT OF CHANGING IMPELLER ANGLE

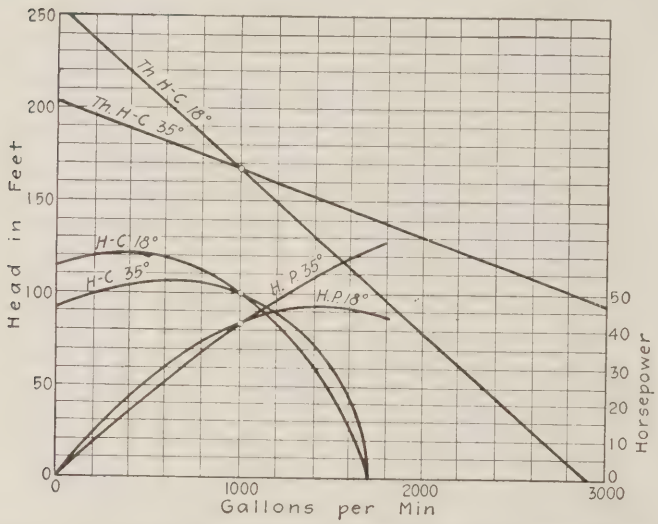

FIG. 9. CHARACTERISTIC CURVES OF TWO IMPELLERS

in order to avoid shock losses. There are two ways in which this can efficiently be accomplished:

1. By means of a volute casing, as in Fig. 1. The velocity of the water moving in the casing toward the discharge is lower than the absolute velocity A, and usually higher than the velocity in the discharge pipe. The shock and friction losses become a minimum for a certain ratio between the absolute velocity A and the velocity of the water in the casing. At this ratio the pump works most efficiently. The efficiency decreases if an impeller is installed that would produce a different ratio. Referring to Fig. 7, the best efficiency occurred at a delivery of 1000 g.p.m. against a 100-ft. head. If it was desired to use this machine to pump only 500 g.p.m. against a 100-ft. head, the efficiency would decrease considerably even if a special impeller was designed and installed. The efficiency would remain constant, however, if V and A were changed in the same proportion as was the capacity—that is, in our case reduced by one-half. This would give the same ratio between the absolute velocity and the velocity in the casing. The head would decrease as the square of the speed—that is as $\left(\frac{45}{90}\right)^2 = (\frac{1}{2})^2 = \frac{1}{4}$, or to $\frac{100}{4} = 25$ ft. *Capacity head and efficiency of a volute pump are therefore fixed and depend on the area of the casing.* It will therefore in practice be quite often the case that the condition point does not coincide with the best efficiency point, as manufacturers limit the number of casing patterns to one or two for each size. To state, for instance, that a 6-in. volute pump has an economical capacity of 900 to 1200 g.p.m. for heads varying from 10 to 100 ft., is misleading. If the economical range at 100-ft. head lies between 900 and 1200 g.p.m., then it will fall at 10-ft. head to between 320 and 380 g.p.m.

2. The absolute velocity A is reduced and transformed into pressure by means of a diffusion ring, consisting of a number of diffusers, placed around the impeller (see Fig. 10). The diffusers are so designed that at the condition point the water discharged from the impeller at the velocity A enters them with the least possible shock. While passing through the diffusers, the velocity is gradually reduced to about the velocity in the discharge pipe. The area of the casing has not much influence on the efficiency as long as the passages do not obstruct the flow of the water. If therefore, as in the case cited above, the capacity of a 1000 g.p.m. pump is to be changed to 500 g.p.m., it is only necessary to design a new impeller and diffusion ring without changing the casing; and the same or approximately the same efficiency is obtained. The diffusion ring pump is therefore more flexible than the volute pump, but the latter is simpler, has fewer wearing parts and requires less expensive repairs. Diffusion rings do not improve the efficiency of low head pumps. Also, so-called "filling rings" for volute

* These speeds are too high for bad water.

pumps fitted into the casing and surrounding the impeller, intended to minimize shock losses, should not be used in pumps handling acidulous water. They only add to the number of wearing parts and introduce troublesome joints in the casing.

A pump of the construction shown in Fig. 1 produces an axial thrust toward the suction inlet because the impeller areas exposed to the pressure within the pump casing are unequal, the area of the front being smaller than the area of the back of the impeller. The unbalanced area in Fig. 1 is $\frac{\pi}{4}(7\frac{1}{4}^2 - 2^2) = 38$ sq.in. Assuming the pump to be working against a 100-ft. head, which is equal to $\frac{100}{2.31} = 43.3$ lb. per sq.in., and assuming no pressure or vacuum on the suction, the axial thrust is $38 \times 43.3 = 1650$ lb. If, as in a four-stage pump four impellers are mounted on a shaft in series, the combined thrust is $4 \times 1650 = 6600$ lb. A heavy thrust bearing would be required to carry such a load and other means are usually employed to overcome it.

The elimination of the axial thrust "on paper" can be accomplished in several ways, but none gives absolute satisfaction in mine service. Excessive suction lift, particles of coal blocking the impeller passages, excessive wear of the internal parts, etc., may throw a pump out of balance and smash a number of the internal parts. Such accidents are costly and must be avoided. It is best to design a pump so that it is theoretically balanced and then add a good heavy marine-type thrust bearing for emergency.

A single-suction impeller, as shown in Fig. 1, can be hydraulically balanced by providing a balancing chamber at the back of the impeller (see Fig. 11). Holes drilled through the back of the impeller connect this chamber with the suction inlet of the pump and the unbalanced area is thus eliminated. Single-suction volute pumps and multi-stage diffusion-ring pumps are mostly balanced in this manner. Volute pumps handling water against heads exceeding 50 ft. are usually built with double-suction impellers. The water enters the impeller from both sides and no axial thrust is produced. The double inlet reduces the inlet area to one-half of the inlet area of a single-suction impeller. The wearing rings are therefore smaller in diameter and the leakage in a double-suction pump is consequently less and the efficiency higher.

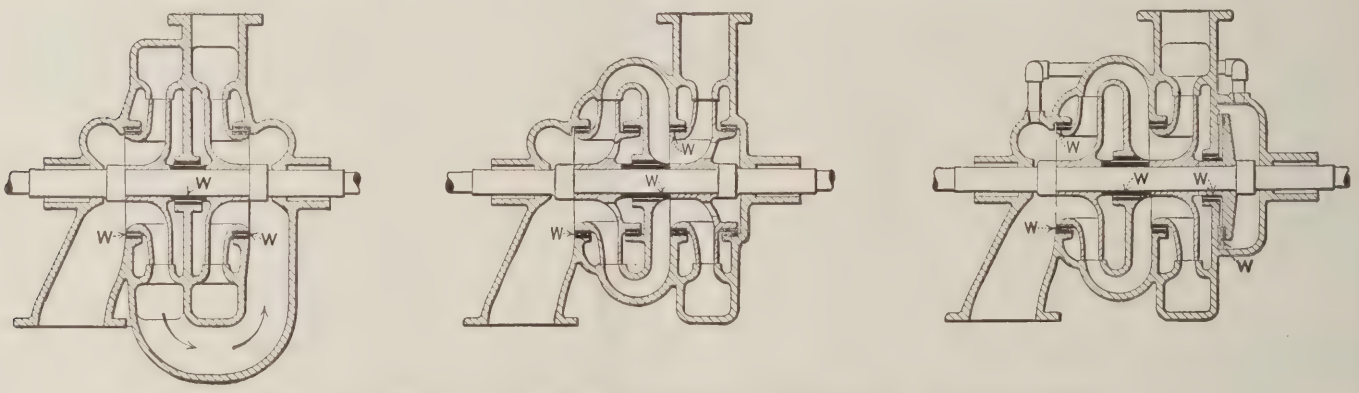
FIGS. 10, 11 AND 12. ARRANGEMENT OF DIFFUSION RINGS AND METHODS OF HYDRAULIC BALANCING

Double-suction multi-stage pumps are not ordinarily used for mine service, as the casing becomes too large and expensive. A single-suction impeller can also be balanced by means of a balancing disk, fastened on the pump shaft and rotating in a chamber placed behind the impeller, as shown in Fig. 12. The disk divides this chamber into two compartments; one is supplied with water at the discharge pressure, the other is connected by means of a pipe to the suction inlet of the pump. The full discharge pressure acts therefore on one side of the disk, and the suction pressure on the other side, causing a thrust opposed to that set up by the impeller. If the diameter of the disk is made equal to the diameter of the impeller ring, the opposing forces are equal and balanced.

This device operates satisfactorily only if a constant

stream of water flows past the disk hub into the pressure compartment and past the disk faces back into the suction, preventing the disk from rubbing on the faceplate. The higher the pressure the higher will be the velocity of the escaping water; and it is obvious that acidulous water will soon destroy the disk hub and the disk faces.

The best and simplest arrangement to balance multi-stage pumps is to place the impellers in pairs "back-to-back" on the shaft, as shown in Fig. 13. The thrust set up by one impeller is thus opposite that set up by the other impeller, and the pump is therefore balanced.



The interior parts of a centrifugal pump that are most subject to wear are the impeller and casing wearing rings, the distance sleeves and bushings, the balancing disk (if one is used) and the shaft bushings. If the peripheral speed is kept below 90 ft. per sec., the wear of the impeller is small and a properly built diffusion ring outlasts two impellers.

Internal leakage takes place at the impeller rings, the distance sleeves and the balancing disk. The more these parts wear, the greater will be the leakage. This may become so large that the pump will not force the water up to the surface. The efficiency decreases, of course, with increased leakage. As it is impossible to prevent wear of the internal parts, the number of these parts must be reduced to a minimum. Pumps that are not equipped with casing wearing rings should not be used in the mines as the casing would have to be rebored in a short time.

The designs shown in Figs. 11 and 12 are also used in multi-stage pumps. Figs. 14 and 15 show the arrangement of two-stage pumps, and in Fig. 13 is shown a two-stage pump of the "back-to-back" impeller type. The wearing parts are marked *W*, and the table below shows the number of these parts for each design:

	Number of Wearing Parts		
	Two-Stage Pump	Four-Stage Pump	Six-Stage Pump
Fig. 13	6	14	22
Fig. 14	10	22	34
Fig. 15	10	18	26

The back-to-back impeller type shows up most advantageously and is best suited for mine service.

FIGS. 13, 14 AND 15. INTERNAL WEARING SURFACES OF VARIOUS PUMPS

Capacity and Speeds for Mine Pumps

It is customary to limit the head per stage for mine pumps to 100 ft. If, for instance, the total head is 350 ft., a four-stage pump should be used. The speed of the pump should be kept as low as possible, but not so low that the impeller diameter becomes excessive. Large impellers produce much skin friction and low efficiency, and the casings become large and expensive. Bronze casings should be used for pumping acidulous water. Cast-iron casings can be used for water containing no acid or only a trace of acid, but the interior parts of the pump should always be made of bronze. Silt frequently causes more wear than the acid in the water. If the water contains a great amount of silt, it is best to use a wood-lined plunger pump. Tables I and II give speeds, efficiencies and capacities of double-suction volute and single-suction multi-stage pumps. The speeds listed are for direct-connected, motor-driven machines for 60-cycle and 25-cycle current. Capacities and efficiencies are average values and will vary somewhat with different makes.

The efficiency of a centrifugal pump installation depends to a great extent on the layout of the pipe line. A poorly designed suction pipe may cause a considerable decrease in pump efficiency. The suction pipe should be as short as possible and absolutely tight; the lift, including friction, should for normal conditions not exceed 15 ft. A short elbow should never be attached directly to the suction inlet of the pump as the disturbances in the flow of the water produced by such an elbow may prevent a proper flow into the impeller and cause a considerable decrease in capacity and efficiency, as well as noisy operation. A foot valve should, if possible, be omitted and the pump should be primed by means of an ejector or air pump.

Short elbows should also never be installed in the discharge pipe; and it should be remembered that for 100-ft. lift every foot of friction saved in the pipe line will mean an increase in efficiency of 1 per cent. When discharging 1000 g.p.m. through 100 ft. of straight 6-in. pipe the friction loss can be taken as 11.5 ft. against 2.8 ft. in an 8-in. pipe. Selecting an 8-in. pipe instead of a 6-in. pipe would save 8.7 ft. in friction head, equivalent to an efficiency increase of 8 per cent.

It seems that a long narrow combustion space is more efficient in burning the gases than a short wide one having the same cubical space. In the long narrow space the gases travel with a higher velocity, which promotes mixing and therefore quickens the combustion. In the short wide space the gases remain the same length of time, but travel slower. On account of this slower movement the gases are less agitated and tend to travel in stratified streams. Therefore there is less mixing and the combustion is slower.—*Bureau of Mines Bulletin No. 135.*

Cost of Reaching the Market

Many Factors Besides Mining Costs Enter Into the Cost to the Consumer, and These Must Be Considered in Reporting on the Feasibility of Opening a New Mine if Financial Pitfalls Are To Be Avoided

By J. F. K. BROWN
Scranton, Penn.

An estimate of the cost of reaching the market in which a coal is to be sold is an important part of any coal-mining investigation. Reasonable accuracy in such calculations is essential, and this can only be secured as a result of knowledge and experience gained in actual operation under a variety of conditions. This subject is so broad, that it is quite impossible to treat it in detail, and so only the main features or governing factors in resultant costs have been considered in this article.

THE cost of reaching the market covers the following ground: (a) Mining costs; (b) transportation costs and (c) disposal costs. It is mere repetition to state that coal-mining costs will vary, these variations being caused by such factors as underground conditions, management, labor, supplies and finance. While all of these exert a more or less potent influence upon the cost of coal, and none may be forgotten in reporting on the possibilities of a coal property, they are all fairly well understood by mining engineers and will not be discussed in detail here.

It is easy to think about mining costs only in making a coal examination. These are so obvious and necessary that they can not well be overlooked, but the costs which stand out prominently are not always the figures which swing the total cost to the profit side of the balance sheet.

Transportation costs, except for those mines which are so fortunately situated that disposal of output takes place at the mine mouth, is a large item and one that demands a considerable amount of floating capital. It is self-evident that the extraction of coal is accomplished at a loss unless the item of reaching the point where sales can be consummated is taken into account at a figure which will permit of the disposal of the product at a profit.

Transportation Cost Quite an Item

Transportation costs can be of two classes—carriage by rail based either on the ton or ton-mile, and sea carriage, generally based on the ton loaded. In the latter case it is usual to include cost of loading and unloading. With rail carriage the mine costs cover coal loaded into cars at the mine mouth, while the cost of discharging is commonly borne by the purchaser, who buys his coal delivered in cars at destination.

In sea carriage, however, in addition to the cost f.o.b. cars, there is the further cost of loading and trimming the vessel except in those few cases where the mine is so located that it can deliver its product direct into the holds of vessels without the use of cars. The unloading of coal cargoes, and more especially where large cargoes are being handled, is often done at the cost of the shipper, who, if his shipments are regular, maintains appliances and equipment at the unloading port to carry on this work. There are conditions, however, under which coal cargoes are consigned to agents on an f.o.b. basis and the colliery company charged with the loading, but not with the unloading costs.

Rail costs are commonly reckoned at so much per ton-mile, and from such figures it is possible to outline the areas over which any fuel can be sold. Where Government ownership exists, and in a country where freight traffic is small and long hauls have to be undertaken through unproductive districts, freight rates can be reckoned as probably at a maximum. On the other hand, where railway lines are privately owned and there is considerable competition for the traffic in a dense industrial district, freights are at the lowest.

Question of Building Tracks

The cost of track or spur accommodation and the car question are important items when considering rail transportation. Regulations, custom and necessity differ in various countries. Some governments will only permit spurs to be built to established stations, while some railway companies will permit connection to any intermediate point. Many railway lines prefer to build the connecting tracks themselves and charge the mining company with the cost of construction, while others leave that work entirely to the coal company with the exception of the first rail length and the connecting points to the main line. They then content themselves with an inspection during and after completion of the work. This may be either rigid or perfunctory.

Whatever the regulations may be, they should be ascertained from the office of the railway company before construction is commenced. Unfortunately, many mines have been started and in the end been left stranded for rail connections, either because the coal company assumed that the railway would provide the needed spur and afterward found the opposite to be the case, or because the coal company assumed that it had only a short line to build and later discovered that it had a considerable distance to cover to reach the nearest station point where connection would be permitted. Both cases are examples of careless investigation on the part of the coal examiners.

The subject of cars to carry the fuel from the mines to the market is frequently a much disputed question. A coal company may own its own cars and have them run over the railway tracks, provided this rolling stock is equal to the requirements of the railway. In other

cases only the railway company's cars are permitted to run over their lines and private ownership of rolling stock is forbidden. Box-cars have to satisfy the aspirations of many coal producers, and the loading of these cars always implies at least a small additional expense.

Railway car supply is a complex subject, and one that is difficult to diagnose. It is easy to imagine that a railway company would be glad of all the carrying traffic that it could obtain, but a few experiences of having to send the whole mine force home for several days will nullify this agreeable impression. It is infinitely better to appreciate these factors before commencement than to learn them from experience at a later date. Car shortage is an item in cost just as serious as a miscalculation in the amount of coal available or the capital required for operation.

Sea transportation may include loading, carriage and unloading costs. Loading is made up of three items—hauling the cars to the loading piers, storage at the piers and actual loading and trimming.

Hauling cars to the piers is railway work and may be done with standard rolling stock or by means of mine cars either of standard or of some narrower gage. The use of an intermediate-sized car and rolling stock is to be deplored, since although it is a system popular in some districts, it usually involves several extra handlings and breakages, and implies that a complete range of supplies and means for repair of another track gage must be maintained.

Commonly the distances from mine to sea are short, more especially in those cases where the lines and stock are privately owned or the property of the mine. Where such a trade is being carried on, as that from the Virginian fields, necessitating hauls of over 150 miles, the conditions are those of ordinary rail shipment.

May Have to Store Coal at Mine

Storage at the piers may or may not be necessary. Where large tonnages are being mined and the vessels to be loaded are few in number, storage is often not required as the combined output of the mines more than meets the demands of the vessels. On the other hand, where the output is only moderate and a shipping trade has to be catered to, it is certain that storage either at the mine or at the piers will have to be undertaken. As vessels cannot afford to wait for cargo, and their arrival cannot always be predicted to the minute, practice has decreed that coal should be stored in pockets at the piers. This system makes vessel loading entirely independent of the mine.

Loading is influenced by the type of vessel, the hatch system and the method of discharging cars or loading from the coal pockets. Standard vessels being rare at present, there are in existence some strange but understandable anomalies in loading conditions. Coal handling and loading runs all the way in efficiency and all the way in method from a row of coolies with baskets, down to loading from a spout or a conveyor belt. Either of the latter systems are not as might perhaps be expected the most efficient at all times. There are cases where the cost of loading by the day wage, by hand and head and basket, is less than the interest which would have to be paid on the cost of a large and modern coaling plant.

Passenger vessels built for tropical voyages have often only small and awkwardly placed coaling hatches, designed for hand loading. The bunkering of one of these steamers becomes a long, slow, tedious operation at a modern coaling pier.

On the other hand, extremely rapid loading is possible where equipment has been standardized and a suitable class of vessel is employed. Hopper-bottom cars of large capacity delivering direct into bins or into chutes is naturally the most direct and quickest loading. With soft coal the breakage is excessive, and so various additional appliances are in use to overcome this defect. Questions of space and storage may, however, bring about the use of some of the other forms of loading appliances, but whatever be the method it should be as direct as possible and eliminate excessive handling of the coal from cars to hold, so that breakage can be avoided and speed attained.

Unnecessary Handling of Coal

Some systems and some concerns have so neglected these simple rules that the coal is sometimes handled no less than seven times before it reaches the boat. Conditions approximating these are more pronounced where coaling piers are not built separate from ordinary cargo docks, and where the coal is run onto the docks at water level.

Trimming is undertaken in order that the vessel may steam properly and be well stowed in cargo space. Trimming costs vary according to the wage scale paid, the labor available, the type of vessel and the tonnage of the boat to be loaded. Each port and each coaling company generally has its own scale of charges. In the case of publicly administered harbors this can be readily ascertained from the office of the harbor commissioners. Coal companies handling their own coal, or railway companies operating the coaling piers, also have a scale of charges for vessels requiring bunker, while they employ their own trimmers and pay them on contract or day wage, charging the shippers of the coal so much per ton or agreeing to handle the coal from the mine into the vessel's hold.

Sea transportation costs vary according to the tonnage carried, the length of the voyage and the time extension of the charter. Naturally, in freights as in everything else, it pays to move, within limits, large tonnages at one time; and when this is combined with a certain continuity of contract freight costs are at their minimum. It is also an axiom that it costs relatively more to move a cargo a short distance than it does to carry it a long distance. That is, one long voyage is preferable to several short ones. Since also a coal cargo can only be carried in the outward direction, it becomes a desideratum on the part of the boat owner to provide some form of return cargo or face a loss. The ease with which a return cargo can be arranged at certain ports is also a factor in reducing costs.

Coal-carrying companies who mine and ship their own coal and find their own vessels commonly do not trouble about return cargoes. To them the handling of the coal is a necessary part of the expenses, and as such has to be met and paid for irrespective of whether or not the boat is usefully employed both going and coming. This is a parallel on the sea to having to send coal cars back to the mine empty on land.

The time during which the charter or lease of the vessel runs has also an influence in the cost of carriage. Naturally the steamship owner, like the landlord, likes a steady tenant and is prepared to make some sacrifice on the chance of having his vessels usefully employed over long periods. The date at which these charters are drawn up, unless special provision is made therefor, is an important point in the ultimate economy. If consummated during a period of high freight rates and carried forward over a longer succeeding period of low rates such a charter may be a godsend to the owner of the vessel but a poor speculation on the part of the coal shipper. The reverse would be the case with a charter made in a period of low freight rates.

Coal unloading may include the handling of the coal from the vessel's hold to the dock and thereafter a screening operation to prepare it for sale. This latter handling might also be termed a disposal cost.

Unloading is carried out by means and systems ranging all the way from primitive to modern. Undoubtedly the quickest, and therefore the most economical under average conditions, is the grab-bucket system, which may be used where the vessel has been designed with large and unobstructed hatchways. The unloading of any vessel should not have to wait on the disposal of the coal, and therefore either a storage space should be provided on the dock or unloading done direct into railway cars. The processes generally are the reverse of the loading at the coaling piers.

Additional Items Entering Into Cost

In certain countries and in certain harbors, mainly those wherein the coal companies or the railway companies do not own or operate their own equipment, there are a number of smaller charge items which have to be paid before all the costs have been included. These are dock and harbor dues, towage, tug and wharfing charges. These may run as high as 20c. per ton and are payable mainly on the tonnage of the boat and on the services required. These items have to be reckoned with if an estimate is being made of the cost of handling the coal to an export market overseas.

Disposal costs are mainly office charges, but may in certain cases include a cartage and retail handling of the coal and maintenance of the necessary equipment. Mainly this work is carried out by retail firms who will contract with the importing company for so much tonnage per annum. Under these circumstances disposal charges are salaries to salesmen, the office staff employed and similar items. This work may even cover office and dock rent and provision and operation of a screening plant on the dock, necessitating the disposal of the small coal produced. In such cases the costs approximate and can be reckoned on the basis of similar charges at the mine itself, provided attention is paid to any differences in labor conditions and other factors which may govern the situation, where the screening or mining operations take place in one land and the unloading and screening in another.

To sum up then, the cost of reaching the market in most cases is by no means covered by the cost of mining. It may embrace many items of expense not ordinarily encountered, but none of which may be neglected in the engineer's report if the owners or lessees of the mine are to avoid financial errors.

Minecdotes

The Story of the Blind Miner

"I have never told this story yet," said the mine boss, "but what some doubting Thomas didn't say I ought to be elected a full-fledged member of the Ananias Union —or words to that effect. But I can vouch for it being the truth.

"When I took the job some years ago as assistant foreman at the ——— mine, they had a fellow working there as a miner who was completely blind. 'Old Johnny,' the men used to call him. He was a prime favorite with everybody, and in spite of his affliction was one of the best miners in the mine. He had been working there for years, and it was positively uncanny, at least to a newcomer, to see the way he could sense his way around.

"Now it happened that a short time after I arrived we ran into a gas pocket in one of the main headings, and to make a connection to air it was necessary to drive a crosscut 60 ft. to the airway. The place was making gas worse than anything I have ever seen before or since. It blew out of a fissure in the rib, under pressure, and you could hear it wheezing 200 ft. before you got to the face.

"We ran compressed air to the face as well as a brattice, but even at that it was impossible to raise a safety lamp over 2 ft. from the bottom without the gas snuffing it out. Naturally, nobody wanted to work in there, and to tell the truth I didn't blame any miner for steering clear of it. Just to hear the gas stewing out of the hole was enough to give anybody the creeps, let alone seeing a gas cap in your lamp as big as it would hold.

"Finally the superintendent offered double wages for any man who would work it, with no takers, until Old Johnny happened to hear of it. He grabbed it at once and went to work in there by himself. Now you can believe me or not, but in due time he made the connection with the airway so that it was possible to get good ventilation and continue the heading as before.

"It was easy meat for him, as the problem of a light didn't bother him any; and in that particular case the fact that he was blind enabled him to make a good piece of money for himself and at the same time enabled the company to get through the pocket of gas in perfect safety."

A rather heavy silence ensued after the mine boss concluded, which was finally broken by the master mechanic.

"If nobody offers any objection," he said, drily, "I would like to make it unanimous that the gentleman be made a *life member*."

[*Coal Age* will pay liberally for short, witty stories suitable for publication in this column, provided the tales are of the mine and have the proper coal-mining "flavor." If they point a moral, so much the better. Dig down into your experiences and share with the many readers of this journal the humorous incidents you have witnessed in your duties around the mine.]

Successful Burning of Anthracite Slush

SYNOPSIS — *Anthracite slush, or the fine material made in preparation that passes through a $\frac{3}{32}$-in. circular opening, has never been considered of commercial value except for the manufacture of briquets. However, this material is now being successfully burned by means of a chain-grate stoker and forced draft.*

PROBABLY every great industry has its waste-utilization of waste-disposal problem. Some, such as meat-packing as an illustration, have solved their difficulties in this direction, and little if any material is rejected or thrown away as entirely useless and unusable.

The coal industry, as well as the others, has had its waste problem. This has lain in the disposal of two products—the slate brought out of the mine with the coal and later separated from it in the process of preparation, and the fine coal produced, for which no commercial demand as yet exists.

Slate and bone are at present disposed of in various ways, one of the most effectual being the pulverization of this material and its flushing back into the old workings to insure surface support. For bituminous slack there exists at the present time a strong demand. In the past, however, considerable quantities of this material have been dumped on the ground and wasted at no small cost to the mine because there was no market for this fine material.

The sizes of anthracite that have been deemed usable have almost steadily grown smaller since the beginning of the industry. At present the only size of this material made which is not considered burnable in ordinary furnaces equipped for steam generation is what is variously known as culm, silt or slush. This is the size that passes through a $\frac{3}{32}$-in. circular opening, the actual size of the various particles ranging from minute dust to the full-sized opening referred to above.

FIG. 1. CAR OF SILT UNDER THE LOADING CHUTE. NOTE THE LARGE AMOUNT OF WATER

Because of the variation in size of the individual particles the interstitial openings are numerous but minute, and the passages through which air may travel in traversing a bed of any considerable thickness of this coal, as that upon a fire grate, are small and tortuous. The percentage of voids in a bed of this fuel is probably about the same as that in a mixture of fine gravel and sand.

The difficulty encountered in the burning of this fuel by ordinary hand-firing methods in boiler furnaces has been the deadening effect of a fresh charge of coal upon a going fire. This arises chiefly from the small air passages previously referred to. Ordinary natural draft, unless caused from a prohibitively high stack, is inadequate to force air through any considerable thickness of this fuel, and as a result where this material is to be burned commercially forced draft must be installed.

The coal department of the Delaware, Lackawanna & Western Railroad Co., at its Nanticoke power plant, is successfully burning this fuel under boilers, thus utilizing a product which has heretofore been considered useless except for the manufacture of anthracite briquets.

The fuel used in this particular power plant is made at the washery operated in connection with the Loomis breaker of the above-named company. The slush, or silt, which passes through the smallest opening of the shaker screens drops into a shallow hoppered tank under the shakers. While being treated on the shakers the coal is subjected to water sprays, and this water of course finds its way through the screen plates and enters the hopper-shaped tank referred to, along with the coal passing the small mesh.

At the bottom of the hopper-shaped concrete tank below the shaking screen the fine coal and a certain portion of the water is drawn off through an ordinary gate valve into a chute below. The greater portion of the water is, however, drawn from this tank at a point considerably above the apex of the hopper, so that little, if any, coal goes off with the bulk of the water. The chute into which the silt and water are discharged from the bottom of the tank leads to a storage bin exactly similar to the bins for storing the other grades of coal. At suitable intervals—that is, when a sufficient amount of this slush has accumulated in the storage bins—it is drawn off through regular chutes into a hopper-bottomed railroad car.

Of course, throughout this entire process, or until after the coal has been deposited in the railroad car, all of the voids between particles have been thoroughly filled, or a little more than filled, with water. This may be clearly seen in Fig. 1, which shows a car under the loading chute almost full of this fine coal. When a car of this material leaves the washery, while the coal is heaped up somewhat above the level of the top of the car, the water is overflowing the sides.

In passing the valve and traveling down the chute, and particularly in flowing from the bin to the car

through the loading chute, this mixture of fine coal and water behaves much like a thick or viscous liquid. At a short distance away the material in the car more resembles mud than it does coal.

So nearly liquid and so thoroughly flowable is this material when it enters the car, that it is necessary, before running the car under the loading chute from the slush or silt bin, to place in its bottom a few hundred pounds of coal of the next larger size in order to prevent the fine material from flowing out of the cracks around the hopper-bottom doors and thus being wasted.

In this condition it is run upon the coal tracks of the Nanticoke power plant. These tracks enter the boiler house at one end and extend throughout the length of the building immediately above the coal-storage bunkers. The coal is here discharged from the hopper-bottomed cars and passes down into the bunkers through a cast-iron grating containing openings about $2\frac{3}{4}$ x $3\frac{3}{4}$ in. From the bottom of the coal bunkers chutes lead to the feed hoppers of Coxe chain-grate stokers.

The fingers (or as they are familiarly known the "piano keys") of these stokers, which form the actual coal-supporting surface or grate, are of special design and contain openings about $\frac{1}{16}$ in. wide and $\frac{3}{32}$ in. in length. Approximately 6 per cent. of the grate surface is made up of these minute air spaces. On the grate of this stoker this fine material, which is carried to a depth of about 4 in., is burned by the aid of forced draft of an intensity of about 1½ to 2 in. of water. Considerable care and no small amount of skill must be exercised in handling this fire.

The fire carried in these stokers is by no means as flexible as it is possible to secure with some types of stokers and bituminous coal. The heat developed, however, is intense, as may be judged from Fig. 4. This is, by the way, a peculiar and in some respects a remarkable photograph. It was taken through the side door of the furnace and shows clearly not only the fire bed with the flame leaping up through it, the minute air holes blown in the fire at points above the tuyere openings

FIG. 2. THE SILT IN COMPARISON WITH A 6-IN. RULE

of the grate, but also the effect of the intense heat developed upon the side walls and setting of the boiler. This is evidenced by the slag formations on the side of the door opening, which somewhat resemble icicles in form and shape.

In this plant at the present time 10 Babcock & Wilcox boilers, each of 303 hp., are now in operation. These are set in batteries of two each. The actual effective grate surface under each boiler is 10 ft. wide and 11 ft. 8 in. long. Four more boilers, duplicates of the ones now in operation (except as to superheaters), are now being installed in the plant. Steam is carried at 155 lb. pressure and 150 deg. of superheat. From the boiler plant the steam is conveyed to the

FIG. 3. UPPER END OF BOILER PLANT SHOWING CARS ON FUEL TRACK ABOVE BOILER BUNKERS

engine room, which contains as main units two Allis-Chalmers steam turbines direct connected to Allis-Chalmers 4100-volt, 565-amp., three-phase, 60-cycle generators. These machines operate at 1800 r.p.m. Surface condensers are employed and a vacuum of about 28 in. is secured. Cooling water is drawn from the Susquehanna River and returns to the same source, the power plant being built upon the bank of this stream. The power generated is transmitted direct without transformation to eight different collieries of the Lackawanna company.

FIG. 4. INTERIOR OF THE BOILER FURNACE. THE CHAIN GRATE MOVES FROM RIGHT TO LEFT

At this and other Lackawanna plants, so far as is known, have been made the only successful attempts to burn an anthracite fuel as fine as that used. The size of the individual pieces of coal may be clearly judged from Fig. 2, which shows this fuel in comparison with a 6-in. ruler. As may be clearly perceived in this photograph, some pieces of the larger sized coal employed to keep the fine stuff from running out of the cracks around the door of the car have been included in the sample photographed. The balance of the sample shows clearly, however, the small size of even the largest particles and gives a clear idea to those familiar with combustion problems of the difficulties in any scheme for the utilization of this product.

This fine material contains from 85 to 90 per cent. as much heat per pound as does the larger grades. The question which has confronted would-be users of this fuel has always been how to get the heat out of this fine coal. It would appear that the chain-grate stoker and forced draft as employed in the Nanticoke power plant have proved a successful solution to this problem.

Who's Who In Coal Mining

W. J. Heatherman

Character, integrity and ability are so plainly stamped on the countenance of W. J. Heatherman, who was recently appointed by Governor John J. Cornwell as chief of the West Virginia Department of Mines, that his face may be said to be one of his best assets. Mr. Heatherman, in reaching his present position, has had no easy road to travel. The standing he has achieved in the mining world is due to no accident, but to his own ambition and perseverance, coupled with a most delightful personality which at once attracts people to him and which undoubtedly had much to do with bringing to him the invitation to accept the post which he now holds.

W. J. Heatherman was born at Malden, W. Va., three days before Christmas, 1884. He is therefore not quite 34 years of age. What education the new mine chief has received has been gained at times which he could spare from work in the mines. The foundation for his technical education was laid in the public schools of West Virginia, supplemented by two years spent at Mount St. Josephs College, Baltimore, and a two years' course in mining engineering at the Ohio State University, where Mr. Heatherman was an instructor in surveying.

Most of his education, however, was gained after he had begun work in the mines. He started in as a trapper boy at the age of twelve, at Powhatan, working for the Powhatan Coal and Coke Co., operated then as now, by Col. L. E. Tierney. Having become interested in the technical phases of mining and desiring to learn all there was to know about the profession, young Heatherman accepted a position as chairman on the engineering corps of the Powhatan company. Observant of the ambitions of young Heatherman, Colonel Tierney presented him, as a Christmas present, with a correspondence course in mining engineering in the International Correspondence School. Equipped partially with an education as a mining engineer gained through a correspondence course, young Heatherman in 1900 became a mine boss for the United States Coal and Coke Co. at Gary, later being made a transitman for the same company.

After completing a two-year course at the Ohio State University, young Heatherman was made chief engineer with the Beury interests on New River. His ability was soon recognized, and in the course of a year or so he was made superintendent of the Stuart Mining Co. at Fayette. Attracted by his ability, the Clinchfield Coal Corporation tendered the young West Virginia mining engineer a position as superintendent of one of its mines in the Big Stone Gap section, Mr. Heatherman remaining with that concern for several years, acting as superintendent of several of its mines.

Another chapter in the career of W. J. Heatherman was written when he became general superintendent of the Main Island Creek Coal Co. in Logan County, continuing in that capacity until he branched out for himself during the last year, at the same time managing

the operations of the Maxine Coal Co., whose headquarters are at Huntington.

The new chief of the Department of Mines is an enthusiastic advocate of safety-first in all its phases. His slogan is not only "First Aid to the Injured," but "First Aid to the Uninjured"; and this forms the burden of his first communication addressed to the operators, mine officials and miners, made after he assumed charge of the West Virginia Department of Mines. One of the first things with which he was deeply impressed when he assumed the office of chief of the Department of Mines was the number of fatal accidents occurring in the mines in this state, a number which is greatly in excess of what he deems it should be.

He has publicly stated that he desires and solicits the coöperation of the operators, mine officials and miners in everything that will assist in placing the mines of the state on a higher standard of safety and efficiency.

Two teams of miners drilled by Mr. Heatherman during his connection with the Clinchfield Coal Corporation won the trophies awarded the best first-aid teams during the Virginia State Meet at Big Stone Gap in the years 1915 and 1916.

W. J. HEATHERMAN
Chief of the West Virginia Department of Mines

The new mine chief's favorite recreation is baseball, and not only baseball as seen from the bleachers or grand stand, but as seen from the diamond. He has played baseball since he was a youngster, and played so well that he could have secured a berth in the Three-I League and leagues of similar classification had he so desired, excelling as a first baseman.

When J. H. Murray and others of Huntington contemplated the expansion of operations of the Maxine Coal Co., they felt no hesitancy in investing additional capital to be expended in improvements so long as they knew W. J. Heatherman was to be in charge of such improvements and subsequent operations, even though he was then engaged in the coal-mining business as an independent operator; and therefore it was with much reluctance that those with whom he was associated consented to release him in order that the state might have the benefit of his services.

Mr. Heatherman and Miss Alice Smith, of Chillicothe, Ohio, were united in marriage in 1908, and have two splendid boys aged nine and seven respectively.

From remarks made by members of the staff of district inspectors of the Mine Department following the first conference held by the new chief, it is believed that he will not only command their confidence, but that of all others with whom he comes in contact.

Open Air Accidents with Explosives

Three accidents within a week, due to explosives, recently occurred in eastern Pennsylvania. All took place out of doors.

In the first accident a large number of drill holes were being charged with 20,000 lb. of dynamite. The work was being done by an expert blaster sent out by the company furnishing the explosive. In some unaccountable manner the blaster detonated the charge in one of the holes and was instantly killed. Although the exact cause of this accident will never be known, it is believed that a portion of the charge became wedged in the hole and, in attempting to dislodge it, the blaster set off this sensitive explosive with his tamping stick.

In anthracite stripping it is the practice to keep the holes a short distance ahead of the shovel and never to charge a hole with black powder while the shovel is digging. As a further precaution, when black powder loading is going on with a shovel in the proximity of the hole, even though the shovel is at rest the smokestack is hooded to prevent the emission of sparks.

In the second accident a series of holes had been drilled, and the foreman gave the blaster instructions to wait until after quitting time before starting to charge them. The foreman then left to attend to other duties, whereupon the blaster and his two assistants began to load the holes.

While the blaster was pouring black powder from a keg into one of the holes, a spark from a shovel that was digging nearby ignited the explosive. Every bit of clothing was burned off the man, and only a small portion of his body escaped serious burns. It is thought that he may survive, but this is considered doubtful. His two helpers received serious burns about the hands and face.

Heavy rains have prevailed during the past month, and after one of these several holes were loaded directly in front of a shovel. The dynamite used was of about 60 per cent. strength. After the holes had been fired, the shovel was moved up and work commenced. Only a few dipperfuls had been taken, however, when the engineer collapsed.

Upon examination it was found that this man had been "knocked out" by the dynamite fumes, the effects of which are well known. The morning was a "heavy" one, and the gases seemed to drift to a point directly under the shovel cab. Thus, while this man was practically working in the open air, he evidently received the full effects of the dynamite fumes.

Tenth Annual Convention of the International Railway Fuel Association

TO STIMULATE greater effort on the part of all concerned in the production and use of coal, the International Railway Fuel Association, composed of the officials of American and Canadian railway fuel departments, in conjunction with coal operators, recently tendered its services to the Government. The offer was accepted by the Fuel Administration and the Railroad Administration, and these two Government departments, in coöperation with the officers of the Fuel Association, arranged for the convention held on May 23 and 24 in Chicago. The speakers who addressed this meeting are all men of national prominence, whose previous experience or present contact with the fuel situation enabled them to speak with authority to mine operators, mine workers, railway officials and railway employees. Special emphasis was placed by most of the speakers on the value of individual effort in connection with coal conservation, as will be evident from a reading of the several inspiring and excellent papers abstracted on the following pages.

Fuel Problem As It Relates to War Activities

By P. B. Noyes

Director, Conservation Division, United States Fuel Administration

FOR nearly nine months the Fuel Administration has been rounding up, as it were, the factors of a problem absolutely new in the industrial life of America. The picture is now complete. The governing factors are before us. Their relations and inter-relations have been clearly determined. The solution, however, of the war fuel problem is a task quite beyond the power of any administration or administrator. It lies in the hands of a thousand agencies and millions of men.

The coal supply is short. Last winter it was short, and the immense new requirements for war purposes threaten to make it shorter still the coming winter. The mines, which must get out the coal, and the railroads, which must carry it, were pressed nearly to their limit before the war. They cannot take on 200,000,000 tons of additional production. Add to this the tremendous burden of war supplies, troop transportation, material for shipbuilding, and food for our Allies, and then picture to yourself what it means to the railways, with facilities little if any greater than three years ago, to provide transportation for 200,000,000 additional tons of coal.

Conceive of this increase as 16 solid trains of gondola cars filling 16 tracks from New York to San Francisco—a veritable freight yard filled with coal cars extending the breadth of this continent. And this represents only the increase of coal transportation demanded of the railroads. All of those four million cars must be switched in and out and carried hundreds of miles by our already burdened transportation system if war demands are to be met and the usual industrial life of the country be at all preserved.

The coal business is in physical proportions so far beyond any other business in the country that emergency remedies which can be successfully applied to any of the others will hardly make a dent in the coal shortage.

And yet, the success of the war is likely to depend just on this supply of coal. Coal to manufacture supplies and ammunition on a greater scale than Germany, and coal to transport these supplies and transport millions of men both in this country and across to Europe, is the first essential of our success. Behind this we have the necessity for coal to maintain life at home, to preserve our economic system and keep our ordinary industries running and keep labor employed.

There has been much talk of shutting down "nonessential" industries, but a little investigation shows that only a short distance down this road lies financial ruin and unemployment of labor on a scale which would bring disaster at home and failure in war.

We are apt to forget that what are now called the nonessential industries are the absolutely essential industries of peace times. They are more than that—they are, even in war times, the essential means for life and happiness to a very large portion of our population. At least 20 billion dollars of capital is invested in legitimate manufacturing enterprises producing goods not strictly needed for the war. Ten million men support their families from the work they do in these factories.

Whenever war industries are threatened with a coal shortage, unthinking people light-heartedly suggest the cutting off of nonessential industries. Last fall lists were repeatedly suggested by responsible people for the cutting off of certain industries as nonessential. It only required a cursory examination of this list of industries to find that they involved the happiness of a tremendous proportion of our working population; that cutting off their fuel supply meant bankruptcy on a scale which would precipitate the greatest panic ever seen in the United States, and the sudden and forcible unemployment of at least five million men. It was thought by some a sufficient answer to suggest the need of men for war work. But the shifting of workmen from one business to another is a difficult and slow process. We know that a majority of the workmen thrown out by such a sudden shutdown of industry would not get employment. Such readjustment of employment would affect only a small faction of the workers. A large proportion of the employees in every factory are not migratory. They own homes. They have lived in the same place all their lives. They starve there rather than move. They do not know where to go for work even if they are willing, and no power on earth could arrange new places for five million men in time to prevent not only hardship and misery but possibly riots and bloodshed.

All responsible agents of the Government now realize that keeping labor reasonably employed and only taking it away from nonwar work as fast as it can be employed on war work, is nearly as important for success in this war as the manufacture of munitions and ships. Granted that we must have 100 per cent. fuel for munitions and ships. We shall fail as a nation if we do not provide this without a complete breakdown of our industrial system.

Fuel is a small part of the raw material of most manufacturing institutions. The fuel expense in most highly organized industries is little over 1 per cent. of the total cost of the goods. On the other hand, this 1 per cent. is absolutely vital. Without it the factory closes. The other 99 per cent. are useless. We are called upon to view a ton of coal as equal to 500 or 600 lb. of ship plates or shells, but every ton of coal saved for our factories means the employment or nonemployment of a hundred men.

Over and beyond the desperate need of coal for war purposes lies an equally desperate need of coal to preserve the lives and happiness of the population. The threatened shortage of coal can easily mean unemployment and financial ruin.

Every extra ton of coal taken out of the mines is likely to keep a hundred extra workmen from idleness. Railway locomotives burn more than a quarter of all the coal mined in the country, and it lies in the power of the railway fireman and the organization with which he works to save enough coal to turn threatened national disaster into national prosperity.

Fuel economy on a scale which will really save the country from industrial disaster demands first, a study of methods and, second, a willingness to take pains. It has rightly been said that if every man who burns coal will do the very best he knows how without a word of new information, the saving effected will result in plenty of coal for every purpose. Under the present stimulus, I credit every one with giving more attention to economy than ever before, but this matter of doing one's best is relative. It is proportioned to the background of necessity which lies in our minds.

Few men ever reach 100 per cent. of their possible efficiency. Most of us never reach 50 per cent. Any man who through enthusiasm or other stimulus gets up to 75 per cent. of his possible efficiency is a brilliant success in his field of endeavor. The only man I can think of who is up to 100 per cent. of his possible efficiency is the drowning man. His "background" is sufficient to bring out all there is in him.

The background of this terrible war is raising the efficiency of every man and woman in the United States. It is raising it in proportion to the desperate character of that background. Those to whom war has not yet appealed as vitally affecting their lives, have little increased efficiency. The more the meaning of the war has come home to us, the more we have approached our possible efficiency. This is a real force and should be applied directly to fuel economy. Only in that direction lies success in winning the war.

What the Coal Operator Can Do To Help Win the War

By Harry N. Taylor

Vice President, Central Coal and Coke Co., Kansas City, Mo.

THREE great factors make up the fuel problem, any one of which can render helpless the other two. These are the producer, the transporter and the consumer. The producer may be ready to ship the coal and the consumer be ready to take it; but if the transportation is lacking, the other two are helpless. The railroads act in a dual capacity in relation to the fuel situation—they are both transporters and consumers. But viewing them from their primary standpoint—transporters—I believe no body of men is more alive to the importance of the great work before it, or will more patriotically perform its duties than the great industrial army of railroad men.

The coal operator is passing through the most extraordinary period in the history of his industry. He is confronted with the task of supplying an ever-increasing demand, while the means at his command are being constantly curtailed and production threatened. His men are being enlisted or drafted into the army, his machinery is wearing out, and to secure new machinery is next to impossible.

His allies—the railroads—are also being called upon to move an extraordinary tonnage created by war demand. This taxes them beyond their power of performance. This necessarily hampers the coal operator, through lack of motive power and shortage of car supply. We are all confronted by a great task, calling for determination and courage if it is to be successfully overcome. Every one of us must first think, then plan, then do, and the do must be spelled with a capital "D."

I have been connected with the coal industry for more than 30 years, and past experience teaches me that the coal man is at his best in times of stress. Trouble does not discourage, but spurs him on to greater effort. In the many lean years of the past, most coal men have had so little profit in their business that they have been forced to meet many emergencies, and they have become adept at turning corners when harassed by adverse conditions. Thus for years we have been meeting difficulties which would have tried the courage of any man; but this very condition of the industry has fitted the coal operator for the great task that now confronts him.

The railroads have had in the past five or six years a situation very similar to that of the coal operator. With constantly increasing costs of labor, material and supplies, with no means at their command to increase revenue to meet the demands made upon them, they have fought manfully against these adverse conditions and have done wonders with the resources at their disposal. Now that the extraordinary demands of the war are forced upon them, they are compelled to face difficulties seemingly insurmountable.

Roads Forced Into Bankruptcy

In the past few years many roads have been forced into actual bankruptcy, while others made heavy drafts on surplus earned to provide motive power and cars to meet emergencies. For years the big shippers of coal have done all they could to aid the railroads, in securing permission to increase rates, and thus to provide means for adequate motive power and cars to properly conduct their business. This was done, not because the coal men are philanthropists, but because they realized that unless an increase was secured they would pay far more dearly for enforced idle time at their mines arising from lack of adequate car supply than the amount they would pay through a reasonable advance in rates.

The demands of the public for coal supply now requires steady and full running time at all mines, six days per week, every week in the year.

As yet only a comparatively few people have realized the great responsibility resting on the vast consuming public, if the threatened shortage in coal supply is to be overcome.

Although the figures available at Washington show that 550,000,000 tons of bituminous coal was produced in the year 1917, still the country faced an actual coal famine. Every railroad, manufacturing interest and individual consumer was brought face to face with a shortage of supply. In ordinary times an increase of almost 50,000,000 tons would have found the coal industry demoralized by overproduction while the actual conditions in 1917 found us destitute of fuel in many localities, found our war preparations hampered, found our railroads and manufacturing plants crippled, and threatened the successful outcome of the war for liberty and democracy of the world.

We produced a surplus of coal, but found coal bins empty. Coal was the mainspring of industry in peace times, but is the very heart and sinews of the country's welfare in times of war.

We have had the experience of 1917 to guide us as to our duties and necessities for 1918. We know we must produce 50 million additional tons of bituminous coal in 1918 over and above the production of 1917, if we are to meet the demands and necessities of the war.

There are two ways by which the threatened shortage in coal supply can be overcome; First, by increased production; second, by conservation. Every effort is being put forth by the coal operators and miners' organization, the individual miners and the railroads to produce the maximum tonnage.

The records of production as reported from Washington from week to week since January first are not entirely satisfactory. One week we show a little gain and another week we show a dropping back. This record, so far this year, compared with the previous year, on the whole shows a slight gain, but not enough to spell security.

We can make a splendid inroad into the shortage ahead of us if we will pay special attention to the conservation of coal, and conservation must be practiced to a greater degree this year than ever before if we are to meet war necessities. If the coal operator will see to it that the miner gives him clean coal, and if the miner will follow out his patriotic duty and clean the coal, as he should, at the face, we will relieve the railroads of the necessity of hauling the impurities, we will add greater

efficiency to the performance of locomotive power and aid in the movement of trains. Clean coal will add to the efficiency of every manufacturing plant and every warship and transport, giving more speed to industry, and will go a long way toward helping win the war by adding efficiency as well as supply. By eternally trying to produce, and infernally trying to conserve, with every effort we have within us bent toward the end of our patriotic duty, with the great consuming public alive to the real situation, with every citizen a helper, not a knocker, we can and will meet this great necessity of coal supply in a manner that will leave enough coal over and above our own requirements to kindle the fire to finish the job when our boys and the Allies send Kaiser Bill where he belongs!

Individual Effort Toward Fuel Saving

By Eugene McAuliffe

Manager, Fuel Conservation Section, Division of Transportation, United States Railroad Administration

THE subject assigned to me, "Individual Effort Toward Fuel Saving," is sufficiently broad to embrace every feature of fuel production, preparation, transportation and consumption. Obvious limitations, however, will restrict me to what would seem, after all, to be the most important angle to which consideration should be given—that of individual effort, greater effort, a more unified effort than we have in the past attempted.

Statesmen and orators have told us we are a great nation. We have come to believe this oft-repeated assertion. It flatters us and it pleases us to be told these things. I confess that I have had in the past three years some fear that as a people we were not measuring up with the illimitable resources and magnitude of our great country, a country of great agricultural wealth, populous cities, great railway systems, all in turn drawing from Mother Earth, from her mines and wells, not only metallic wealth, but the coal and oil on which we depend for heat, light and power, on which our whole industrial and transportation system rests.

No country, no people, can be truly great as the result of individual achievement. We must keep step with and attune our ears to the music of the march of the human race, for while monarchies and republics have risen and fallen the human race has pressed on to better things. The struggle upward has been at times a difficult one; human suffering, blood, misery and brutality have marked the way.

At the Threshold of Greatness

This war will fix our place unalterably; not as one of the nations, but the greatest of all nations in the world, provided each of us does his part. We are at the very threshold of greatness, the door is wide open, and we are about to step inside. When we enter we will be a fully integrated people, with no doubt or question of allegiance; there will be no hyphenated Americans, no Northerners, no Southerners, no Easterners, no Westerners. Despite all our misgivings we will arrive on time; we are now entering the terminal; the signs are too patent to admit of doubt; the way the country has swung in a few months from a nation committed to peace and proportionately defenseless, into one with a great compelling purpose, a great duty, a great army and navy, has been marvelous.

No one with power of perception can look into the clean-cut faces and at the upstanding bodies of the thousands of young men wearing the blue and brown, who crowd the trains, "going down to the sea in ships," and fail to see in them the crystallization of two years of patience under insult and provocation; aye, challenge. Who of us now fails to recognize the German submarine that called at one of our eastern ports one Sunday morning two years ago, destroying five unarmed ships a few hours afterward, or the flamboyant "Deutschland," as less than a taunt and a challenge?

We are making tremendous strides toward greater individual effort. We have passed the first milepost; but what we who remain at home, we, the real reserve force of the American army must do, is to complete the work of reconstruction of our daily lives so as to make ourselves a living, breathing, fighting part of the country's military force, standing unalterably behind the men at the front, who—our sons and brothers—are the real "shock troops," the first line, depending on you and me to support, whether the fortune of battle sees their line move forward or, with military elasticity, settle back.

Some time ago a friend said to a young soldier who was leaving for France, "It is a great thing to be able to go abroad to fight for your country." "Yes," replied the soldier, "it is also a great thing for you who must stay at home to make and keep it a country worth fighting for."

We must work and we must save. The purchase of a few Thrift Stamps and the denial to ourselves of white bread is not enough. We must look on the winning of this war as a sacrament that it is our great privilege to partake of, and the acceptance of that sacrament means the consecration of all the mentality we can command; all the labor of our hands that we can muster; and most of all, the one compelling idea that all we do, all we can do, is not after all a duty, but instead, an inestimable privilege.

When I speak of working and saving, I wish to speak to you as Americans all. I do not mean that one class shall work and another class save, but that in this struggle each man and woman should practice more self-denial and perform more service. We must increase the output of the shop, the mill, the mine and the railroad. We must work more hours, show a more intensive application, restrict the number of holidays, and most of all, find our place and stay there until war expediency or necessity calls for a transfer. The tremendous expansion that the war has brought about has made us feverish. The job offered just beyond appeals to us, and we move; we move again and again, only, as is frequently the case, to come back at last to our original position. The loss of effort that distinctly belongs to our country is most serious, with nothing of gain to show in its place.

War a Contest of Skill

War is a contest, not alone of fighting skill, but of mining skill in tons of output; of railroad skill as measured by raw and finished materials moved, of passengers, including soldiers and sailors, moved. We are, as I said before, soldiers all, perhaps ununiformed, but standing behind our boys who are the first line troops, standing behind that first line in solid formation with every faculty alert and active, every muscle strained, ready and anxious to give support when the assault comes, and not a shifting, careless, carefree, dollar-seeking crowd, careless of the measure of duty we perform, indifferent to the quality of the material we produce, indifferent as to whether it arrives on time or otherwise.

There can be no middle course; we must take on more responsibility, more work. One-third of the man-power of the country, or more than ten million men, are now directly, or indirectly, engaged in the war; and the end is yet far off. The casualty list, as yet a tiny, trickling stream, will soon grow into a brook; it will pause as it runs past the door of many, many an American home—at the home of the worker in the mine, the factory and the ship yard; the home of the conductor and the brakeman; the engineer and the fireman; the dispatcher, the roundhouse man and the superintendent; at the home of the farmer and the plainsman; at the doctor's door; the lawyer's door; the capitalist's door; wherever the blue star of service hangs in the window. And they are becoming numerous now, the million mark has been passed already—that stream will leave a stain of blood, of tears, of sorrow.

If we are to prevent this brook from growing into a river, a river of American and Allied blood—the best and most chivalrous blood the world ever saw, blood which courses through arteries and veins under the inspiration of ideals such as the world never before advanced, ideals that carry no taint of

lust for land or wealth—we must as miners and railroad men mine coal, mine clean coal, move coal and save coal; we must crush our individual prejudices, our likes and dislikes; we must "carry on"!

A few days ago I reread the story of the "Oregon," and that memorable journey of 20 years ago from San Francisco to Santiago, Cuba. There was not a single American, man or woman, then living, who did not follow Captain Clark and his magnificent crew of men through every one of the 16,000 miles that the "Oregon" drove on her way to join the South Atlantic fleet for the defense of our country in the war then impending. I want to retell in a few words the story of the "Oregon." To my mind that story is our American Odyssey. Her story will appeal to motive-power men, to machinists, to engineers and firemen, and I think to miners.

"Oregon" Built on Honor

The "Oregon" was a creation of the West. She was built in San Francisco by the Union Iron Works, and Captain Clark said, "She was built on honor." When her builders, after installing first-class tubes in her condensers, found a superior metal, they took out the first set of tubes and replaced them with the better article at their own expense. Her builders started right. Is it any wonder that she was built and manned right?

On Mar. 19, 1898, the "Oregon" steamed out of the Golden Gate, down the west coast, from temperate California to the scorching equator. You can imagine the heat and discomfort of a ship's stokehold in the torrid zone, fresh water and ice alone making living possible. At this juncture the chief engineer reported that the use of salt water in the boilers meant scale; scale meant coal; and most of all it meant loss of speed, loss of ability to maneuver quickly when the supreme test came. The crew as one man told the officers to reduce the supply of fresh water issued to them, and the use of ice was entirely restricted to the firemen and coal passers.

On swept the "Oregon," her engines throbbing, her furnaces glowing down through the tropics, into the icy, storm-swept Straits of Magellan, where runs, it is said, the swiftest and most treacherous currents in the world. Captain Clark admits bad moments as he approached the "end of the world." But the "Oregon" steamed on, her boilers were kept clean and tight by the sacrifice of her crew, the steam pressure never failed. The condensers built on honor maintained the required vacuum, her heavy bearings ran cool.

The Straits were passed, and the run up the east coast toward the tropics was well on. Then the officers, concluding that the Cardiff coal taken on at 'Frisco should be conserved for the coming hour of battle—for the news that war had been declared reached the ship at Rio—sailors and coal passers began the exhausting work of rehandling the cleaner, higher grade coal, placing it in bunkers where it would be ready for the supreme hour.

This, to my mind, is the true definition of quality. Johnson's, Worcester's, Webster's, all the world's dictionaries in fact, never defined the word quality as did the crew of the "Oregon." They knew coal, clean coal, coal of quality; and they knew that without clean coal the "Oregon's" guns would not save her from defeat.

Can we not visualize the value of clean coal, mined and loaded on honor? Its value to the men who stoke and sail our transports, laden with the living, breathing embodiment of the million blue stars that show in our windows at home, stars whose azure blue will soon, alas too often, turn the color of hammered, fire-purified gold? Its value to the men who man and fight our battleships and our destroyers, who convoy the star-laden transports? Its value to the young men just enlisting in the great transportation army, the locomotive firemen, young men fresh from schools, farms and shops, to whom the work is now strange and arduous? What does not clean coal mean to all of these? When we pause to reflect how far-reaching is our thoughtlessness we often shrink from the study.

Cruise at an End

Sixty-five days after leaving 'Frisco, on May 24, 1898, Jupiter Light on the Florida coast streamed out on the "Oregon," and the memorable journey, which crystallized in the birth of two new republics and the rending in twain of the western continent, the dream for centuries of kings, statesmen and engineers, was at an end.

There Captain Clark received a terse short order from the Navy Department, the substance of which read, "If in need of repairs go to Hampton Roads; if not, go to Key West, coal and join the Atlantic Fleet." The "Oregon," built by Americans, of American-made steel, whose sheets, seams, tubes and stays were driven together by Americans, whose shafts and bearings were forged, wrought and scraped to a fit by American mechanics, whose bunkers contained a remnant of clean Cardiff coal reinforced by clean, mined-on-honor coal, from American mines, answered, "Ready," and turned her prow toward the shores of struggling, monarchical-cursed Cuba, where that festering old-world product, Weyler, then reigned supreme. She took on board, on May 27, sixty men from the Chicago Naval Reserve, young men whose whole training was received within sight of the City of Chicago. On Sunday morning, July 3, the Spanish fleet came out of Santiago Harbor in battle formation, while the "Oregon," stripped of every superfluous impediment, deckboats, ropes, stanchions, every possible obstruction out of the way, her decks sanded, the gun crews standing by the guns, naked to the waist line, sprang, under the impulse of her engines to the head of the line. And, at 9:27 a.m., her guns fired the first shot in an action that quickly ended a drama which closed with the furling of the Spanish flag and the end of old-world domination in the western hemisphere.

Can we not as miners and railroad men strip ourselves of all passion for profit, all controversy and prejudice, all obstruction, of whatever character, and go out with the determination to forget self, with the firm determination to follow our ideals, the successful conclusion of which will offer wordly opportunity without end?

Perhaps in passing I might well speak of what, to me, seems a great and already flowering field of opportunity, one that reaches out to the miner working in the bowels of the earth, out to the railroad man in the cab and the caboose.

Twelve hundred years before the coming of Christ, Tyre, on the Syrian coast of the Mediterranean Sea, was the greatest seaport of the world. Her merchants were known as "men of Tyre," her vessels were known as "ships of Tyre." Her commerce made and unmade men, cities and principalities. With prosperity came love of luxury, selfishness and other evils, and the command of the seas passed to others.

Seven times since then the over-seas commerce of the world has changed hands; early in the nineteenth century Yankee shipbuilders constructed clipper ships, with keel, ribs and sheathing cut from Maine forests, and with masts that were so tall as to seem at night to carry their tops through the stars, claiming the commerce of the world.

Then came Sir Henry Bessemer, and cheap steel—and Great Britain won back her place as mistress of the seas. And the sun set on the clipper-rigged ship of 50 tons burden, manned by men who were hardy and courageous enough to drive their ships through a gale, every inch of canvas set, at 18 knots an hour. Perhaps we yielded to staid Britain more easily than we would have done if the West—California, Oregon, Washington, the work of spanning the continent with iron rails, the eternal lure of the West—had not beckoned. That work is now done. There is now no frontier, and we are turning back to the sea for new adventure.

Shipyards Busily at Work

In one shipyard alone men are working on 50 keels at one time. From British Columbia, down the west coast to the end, and from Texas to Maine the shipbuilder is carving out the greatest merchant marine the world has ever seen—single ships into whose holds will be poured the contents of hundreds of freight cars for transport to the ends of the seven seas. Our army officers are building the greatest port facilities, warehouses and terminals ever conceived. All of which makes a new era.

What a vision of opportunity this offers to all Americans; not alone to the men of New England, but to the men of Kansas, Nebraska and the other inland states; to even the men of sun-baked Arizona. This means transportation to the men of the rails; coal to the men of the mine; glory and greatness for us, Americans all!

Individual Effort and the War

By E. N. Pratt
President International Railway Fuel Association

THIS war is indeed a serious matter, the winning of it a stern and determined necessity to us all. As individuals we take a back seat for no one when it comes to patriotism, but it has been my experience and observation we know not always wherein our individual duty lies nor do we sense its importance in the big game. We are wont to say: "What's the use of the extra exertion to save a shovelful of coal when another can save a ton?" "What's the use of unloading a car of coal a day earlier when we see trains of coal remaining unmoved daily?" "What's the use of firing a locomotive with care when the train dispatcher holds us an hour on a siding?" "Why repair a car today by extra effort when there will be 'just as many' tomorrow?"

It reverts to the old Bible story where the master called his servants together and gave talents or responsibilities to each according to his ability. "And to one he gave five talents, to another two, and to another one."

Some of us can do more than others; such have the responsibility equal to five talents. Others are in a position to do less, but all of us have it in our power to a greater or less degree to help win the war by doing our best. There is an old Scotch saying that "many a mickle makes a muckle." It is not expected that the miner can do as much as the operator, but both can do wonders in the improvement of the quality of fuel coal if their heart be in their work. The stationary fireman can do less toward fuel economy than the manager of the plant, who can provide efficient devices. Neither can the locomotive fireman save as much coal on his one engine as the train dispatcher with dozens of trains on a single track road, but each can and must do his part.

There are three items in this tremendous fuel problem—production, transportation and consumption—and the railroads are largely responsible for all three; for production in so far as concerns the delivery of machinery and supplies to the mines and a car supply for the coal produced. But the miners and operators both can do much in this particular.

How often have the mines dropped empty cars by the shaft for some trivial reason? This might be refuse in the cars, a hole in the floor or sides, a brake chain broken. How little effort on their part would avoid this loss of use of one or more cars for a whole day? I venture to say that this trivial item amounts to several thousands of coal cars each day.

The next item is transportation, largely by rail, some by water. Railroad men are a hardy and earnest lot and not easily discouraged, working every day in the year including Sundays and holidays that their task may be accomplished with credit to themselves, their employers and to their country. But when, last winter, after weeks of continued and unprecedented snow and cold their locomotives were compelled to operate with added disadvantages of poor and dirty coal, it was perhaps the greatest obstacle of all and many a locomotive died and its train was abandoned for this reason.

I have yet to see a miner or operator who would defer to the railroad man in the matter of patriotism or loyalty to country, and I believe if the proposition is put squarely up to the heart of the man that there will be no Sundays or holidays in either the mine, or the railroad, or in the coal yard, any more than there is Sunday or holiday in the trenches with the Hun facing our boys and the Kaiser menacing our free institutions.

Notwithstanding the fact that the railroads are great users of coal, the public should bear in mind that others are also responsible for waste. Therefore, when we seek the greatest economy in the use of fuel there is a tremendous need of an educational campaign at the kitchen stove, the house heating furnace, the power plant, the coke oven and the kilns that bake clay.

Yet this 27 per cent. of the coal which is used by the railroads is so large that we hope by care and close attention to details, not only as to firing, but better repair of locomotives, more care in dispatching and moving trains and better operation on the part of the engineer, to save millions of tons of coal and millions of gallons of fuel oil. The War Department's arrangements for deferred classification for skilled railroad men, places them under a peculiar obligation for extra effort in their work.

Superheating has been proved practicable and each locomotive so equipped saves hundreds of tons of fuel per year besides rendering faster and better service; hence the present practice of placing superheaters upon the larger locomotives passing through the shop should be continued as far as possible, considering the scarcity of materials and skilled labor to apply them. The locomotive feed-water heater also offers an attractive field for economy and efficiency and well warrants careful and continued experimentation.

It has been said, "Ships will win the war," "Food will win the war," "Coal will win the war"; but I tell you it is individual effort that will solve the fuel problem and thus render its great share in winning this war for democracy.

The leading feature of the morning session on May 24 was the thunderous applause which greeted the announcement of John P. White, former president of the United Mine Workers of America, and now labor advisor for the United States Fuel Administration, that peace in the American coal fields was assured for the duration of the war. The 1200 railroad men and coal operators who packed the hall gave White an ovation when he declared the 700,000 American coal miners are eager to work every day, Sundays and holidays, getting out the extra 200,000,000 tons of coal that will be needed this year if we are to keep business going in such a way as to win the war. He said the 87,000 miners of Illinois alone, who worked only 160 days and mined 60,000,000 tons, could get out 150,000,000 tons this year if enabled to work full time.

"Let the railroads quit haggling over the price and start buying their coal," said Mr. White. "Everybody else will follow suit, production will rise, and we won't have any coal famine next winter. The one mistake that has been made," he added, "was in talking price instead of production."

Claxton E. Allen, deputy fuel administrator for Illinois, said records of all coal dealers are being kept, so that if necessary the administrator can take coal from those who have a surplus and allot it to others who have none, if that measure prove necessary to prevent suffering next winter.

"Fuel Oil and the War" was discussed in a paper sent by M. L. Requa, director of the oil division of the Fuel Administration. The diversion of oil tankers from coast lines to transatlantic army supply service make it necessary for the railways to haul an extra 100,000 barrels of oil daily from Southwestern fields to the North Atlantic war-industry centers. Pipe-line deliveries are to be increased by 20,000 barrels daily. Fuel-oil users were urged to increase their storage capacity.

H. A. Garfield, the United States Fuel Administrator, sent a telegraphic greeting to the convention, emphasizing the national need for all fuel users to avoid waste.

National Coal Association Meets

National Coal Association began its first annual meeting in Philadelphia on May 28. The chief address of the day was made by J. D. A. Morrow, Director General of Distribution for the United States Fuel Administration. An abstract of his address is given below.

EVERY country that has gone into this war has promptly found itself faced with a difficult coal problem. In Great Britain, within six months after war had been declared, 250,000 coal miners had enlisted, and the production in Great Britain fell off 25 million tons. The railways were congested with traffic, and the country faced an industrial crisis.

England met that problem by taking over her coal industry absolutely, by fixing prices, by zoning the movement of coal on her railway lines, by putting into effect regulations concerning distribution and supply of coal more rigid than anything we have had in this country. In Germany, the production of coal fell off 35 million tons in the last six months of 1914, which was a reduction of nearly 20 per cent. In the next year, the production declined another 12 million tons.

We have no authoritative figures of the German industry since the year 1915, but we do know that they have been so short of coal in Germany that the suffering there among the ordinary people during the winter was more severe than anything we had in this country, and strict and rigid measures have necessarily been imposed by the German Government, in order to support the war machine.

The important French coal fields were overrun by the enemy at the outset of the war, and production was cut squarely in two. The supply there has been cruelly short, and every pound has been distributed by the Government. That has been the case also in Italy.

Coal Crisis Nothing Unusual

Thus it is nothing unusual for us to have a coal crisis in this country. You are all familiar with the insatiable demand for coal that coincided with congested traffic on our lines, and within six months after the declaration of war the United States had set up a Federal Fuel Administration, the industry was under Governmental control, and we had followed to that extent at least in the footsteps of other important belligerents.

So it is that this industry now faces a set of conditions it never faced before at the beginning of a coal year, and I think it is entirely true when I say that upon the wisdom of the manner in which the coal people of the United States meet these new conditions and upon the energy of their efforts will depend largely the success of the Allies in this war; because you all must know that a great deal of the industrial activity that is to support the armies of Great Britain, France, the United States and Italy will rest upon the manufacturing industries of the United States, and this goes back squarely to the coal mines.

Now, when I took up the work of directing the distribution of coal, it appeared to me that one of the first things we needed to know was what the requirements for coal would be. Nobody knew how great the real need for coal was. We want to know where we stood with reference to the coal demand for the coming year. To get that information we obtained reports from more than 100,000 industrial concerns, stating the exact quantity they consumed yearly. We obtained reports from 40,000 retail dealers covering their annual deliveries. We obtained reports from the Shipping Board, the War and Navy Departments, and from other Government sources, regarding the building of new factories and extensions to old ones, and the increase of activity in other plants. That information was checked up by the fuel administrators in the more important states. We also called upon private sources of information. When we had those figures together, we found that to run the United States on a war basis this year we need 735,000,000 net tons of coal.

Anthracite Production Will Be Short

It seems likely that the production of anthracite cannot exceed the output of the past year, namely 89,000,000 gross tons. The difference must be made up out of the bituminous mines. The bituminous mines of the United States this year are called on to produce 85,000,000 more tons than they produced last year, which was a record year.

To give you some measure of the responsibility that rests today on the coal producers of the United States let me say that they are called upon to produce more coal this year than all the mines of all the rest of the world combined.

As an example of needs, one single war plant today is calling on us for 5000 tons per day. On the first of July that tonnage will jump to 7000 tons a day, and that means 2,500,000 tons of coal a year.

Another plant equally important on Aug. 1 will double that demand exactly. Another group of war plants will ask us before the year is over for 1,500,000 tons of coal per month. Four new Government war plants this year will consume more coal than all the manufacturing plants, ships, power plants, gas works and street railways consumed last year of bituminous coal in the entire state of New Jersey. The demands for bunker coal for ships in the North Atlantic this year will be materially increased over last.

These are some of the factors that go to make up this demand for coal that enter into the total of 735,000,000 tons. When we face the question of whether that coal can be produced the question is immediately asked, Can the railroads furnish transportation enough to haul it? That is a question that the Railroad Administration will have to answer. The Fuel Administration and the Railroad Administration are working together in the closest harmony.

Mr. McAdoo and Mr. Gray are fully alive to the supreme importance of furnishing transportation enough to give this matter of coal its proper attention, and you may rest assured that they will bend every effort to accomplish that result.

We are now getting distinctly increased efficiency in the transportation of coal because we are working hand

in hand with the Railroad Administration. When I say that I doubt if the railroads can haul that tonnage of coal, whether they can transport it properly with respect to the Eastern part of the country, it does not imply any criticism of the Railroad Administration; it is simply a recognition of the fact that the roads are overburdened with war traffic and that if they furnish the transportation to turn out this tonnage they would do so at the expense of steel, iron ore, cotton and wool and food supplies, and other equally vital commodities, and we would gain nothing. So there has to be a consonance of action in the administration of transportation; and the portion of coal that can be moved and will be moved must be carefully worked out with respect to what necessarily must be furnished other lines of goods.

Domestic Consumer Must Be Cared For

Under these circumstances, then, we clearly and definitely face the prospect of a slight shortage of coal this year. Under these conditions we are trying to see that the domestic consumer is taken care of; that the supreme important users of coal get their supplies, and that if any is left that can go to the less important consumers there is where it will go. This is precisely the plan on which we are now running. This involves a decision as to who are the supremely important users of coal. That is a question that now is definitely settled by the decisions of the War Industries Board. That board is authorized by the President to decide on preferences and priorities in the deliveries of raw material; in other words, to decide who is entitled to supplies of such raw materials.

Bernard M. Baruch is chairman of that committee, and he has full authority of the board to see that the railroads and the ships and the food plants and other important war industries receive their supplies. Plants will be asked to state from day to day the amount of their consumption and the tonnage that is on the way to them, and then they will be granted such amounts of coal as the judgment of the board dictates.

In order to make sure that an equitable distribution is had between these important branches we have to get some very definite information about where the coal is going. We are now in the process of simplifying and reducing all kinds of information and getting it down to the lowest possible terms.

We intend to require every industrial consumer of coal in the United States to register and to report weekly his exact amount on hand, his consumption, his receipts and the amount that is moving to him. If we have all this information it will enable us to act intelligently; for we will know, at any time, how any given plant or industry or section of the country stands with respect to its coal supply, and it will then be possible to prevent trouble before it occurs in many instances, rather than to try to cure it afterward.

The Fuel Administration also thinks it is necessary to get consumers of coal to cut out a part of the waste in the use of coal. As coal is now burned, not merely by domestic consumers, but in many steam plants, there is an important element of waste. The Fuel Administration is organizing a conservation division which is to inspect the plants and teach the users of coal better methods of burning it in order that tonnage may be saved. It is estimated that if this can be done on a large scale this year it will be possible to save perhaps 20,000,000 tons of coal. Unless this is done many plants necessarily will be without coal and to some extent will have to curtail operations.

I want to make it clear that the Distribution Division of the Fuel Administration intends to be sufficiently in control of the situation to make sure that the domestic consumer gets his supply, that the railroads have theirs, and that the important war plants are all running, and that our ships get back and forth across the Atlantic. If we do that, if we take care of the domestic consumer and keep these plants running, it will be possible for us to avoid the suffering that occurred last winter and the working machinery of the United States will not lose one single stroke for lack of coal.

Since we are called on this year to produce and distribute more bituminous coal than all the other bituminous producers in the world combined, it goes without saying that we need a man with outstanding capabilities to handle that feature. We found that man in A. W. Calloway, president of the Davis Coal and Coke Co.; and since the day he came to the Fuel Administration there has been great advancement made in the development of means of coal distribution.

Some of the other men that we have in the Division of Distribution are Assistant Director S. L. Yerkes, of Birmingham, who is one of the most capable men in handling details I have ever met. The management of the distribution of coal in the Northwest and for Canada is in the hands of C. P. White. He has spent years in the Northwest. The distribution of railroad fuel will be in the hands of Walter A. Marsh. The tidewater distribution is in the hands of Mr. Cochran, formerly coal traffic manager of the Baltimore & Ohio, who is assisted by two other gentlemen.

Where the Consumer Comes In

It may be asked, Where does the consumer come in? He comes in in two ways: In the first place these coal men have nothing at all to do with the price of coal. We want nothing to do with it. If we get coal to the places where it ought to go, we will have all we can say grace over. The consumer is also represented in the Distribution Division through the state fuel administrators and their county chairmen, who are intimately in touch with the respective localities. The War Industries Board has asked that in the application of its rulings the state and county chairmen shall decide, in their localities, what consumers and plants come within the designated classes. These men are on the ground and they can find out the facts more quickly than there is any possibility of our finding them out in Washington.

The work of the state fuel administrators and county chairmen heads up in Washington in the Director of State Distribution, A. M. Ogle, who has just been appointed. This means that there will be someone at Washington whose business it will be to see definitely that the work of the state fuel administrators is properly meshed with the other work; in other words, that, to use an expression in Washington, we make sure we

all coördinate. This official will also see that general plans for the distribution of coal are carried out uniformly in the different states by the various state fuel administrators.

What I consider the important part of the Distribution Division in the Fuel Administration is made up of the coal operators and coal salesmen of the United States. It is our theory that those men comprise a highly efficient body of coal distributors, each one of whom knows intimately the business needs of his own customers and his own sections of the country. Those men will largely effect a fine distribution of coal. What we need to do is to organize and unify their efforts and direct them along lines that may be necessary, in order to get the supply of coal where it is needed at the time it is needed; in other words, to make sure that the preference consumer is really preferred. We expect a large part of the output of coal to move along the lines it would ordinarily move, through accustomed relationships and channels of business. It is only necessary to interfere with that movement in order to make sure that some important war plant is not only getting its current supply of coal, but building up a stock for next winter, and to make sure that the retail dealers are getting their coal in plenty of time; to make sure, in short, that coal is not diverted into unimportant and wasteful channels. To the extent that that may be necessary we may have to interfere with business, to take care of some particular consumer or plant, but I think that that interference will be reduced to a minimum. This is one of the misfortunes of war. It is not a desire on the part of the Fuel Administration; it is a thing we view with regret, but with a feeling that it is necessary.

Zoning Plan Benefits Railroads

The zone system of distribution was put into effect before we started, and we have simply gone ahead and carried out the plans submitted to Mr. Garfield. It has proved beneficial to the railroads. The vice president of the Norfolk & Western R.R. gives some idea of how it is helping that road. He says: "A comparison of the movement of loaded coal cars in our coal districts during the seven-day period May 4 to 10, 1918, to determine the advantages derived from the zone regulations, indicates that there was a saving in loaded car mileage in coal fields of 15.2 per cent. or 6982 loaded car-miles in seven days. This is simply the saving of car miles in the coal regions on our lines and does not take into account the saving that has been effected between the origin zones and the points of destination by the elimination of cross hauls."

This is indicative of the important saving in transportation that was effected by the zoning of coal. That zoning no doubt interfered with customary trade relations, it interfered with the customer in getting his supplies. We have this evidence of the fact that the sacrifices made have greatly helped our transportation problem at a time like this, when that is all-important.

To date we have been most admirably supported by the coal men themselves. There have been times when we have made mistakes, made lots of them; we will probably make a good many more. Nobody knows everything about the coal business nor even a small part about all of it, but we are trying to get together in Washington a personnel of leaders in this business in positions of responsibility, men that the coal industry can follow with confidence and respect.

When we do make mistakes I hope that the coal men will do what they thus far have done. They have come and said, "If this is what you want to do, you are making a mistake in the way you are going about it; we feel that you can accomplish better results by doing it in such and such a manner." And in every instance when coal men have come to us in that manner whoever it may be that is particularly affected and concerned with the problem has sat down with those men and said, "Well, let us get together and fix this up right." They have met us halfway, and so far as we are concerned we hope that will continue to be the practice in working out the most effective distribution of coal this year.

We now understand that for modern war to be anywhere near successful the armies in the field must be supported by equally effective and magnificent war machines built up in the industrial life of the country behind the armies. Germany had exactly that kind of an industrial machine completed before ever this war began. The entire electrical and chemical industries were centered in four groups of producers. The blast furnaces and iron men of Germany were organized in the Rhine basin into one single centralized concern that controlled 97 per cent. of the output of pig iron, gray iron, spiegel and other products of that character, and it was intimately related with the single central agency, the Stahlwerks Verband, which controlled absolutely the production and sale of steel in Germany.

The important part of the coal industry in Germany was in the Rhine Valley. That was the part that supported the steel plants and the great industrial activity of the German Empire. And the coal industry in that section was organized into one single, central concern, which had in its hands the control of the entire distribution of coal throughout Germany. That organization was matched in the Silesian coal fields by a similar organization, not nearly so important or large, because the production was not so large. That organization in the Rhine Valley was intimately related with and connected with the combination of iron and steel producers, and then in turn with the important electrical and chemical concerns. Thus when Germany undertook to swing her industrial machine into line behind her armies she needed only to get in touch with the fuel leaders who were responsible for the action of the other industries. When Germany set up what would correspond to our Fuel Administration, the major part of the work was already done.

It is equally necessary for us to build up here an industrial war machine that will support our military war machine just as effectively as does Germany's. Just as the soldier has to subordinate his wishes to the general plan, so the coal man will find it necessary in many respects to lay aside personal desires and privileges and submit his wishes to the general plan for the industry as a whole in support of the war program.

For the coal man to take that action, to play that part in the prosecution of this war, there will be no sleeves with chevrons, no shoulder straps with stars, no military medals or anything of that kind, but he will have the consciousness that he is definitely doing his part to make the world safe for democracy.

Railroad Fuel Controversy Settled

Settlement of the railroad fuel controversy is regarded here as an unqualified victory for the coal operators, championed as they were by Dr. Harry A. Garfield and his organization. The fact that 10c. a ton was stricken from the price has brought in some protests from operators but, as a whole, operators appear to be more than satisfied by the establishment of the principle that railroads are not entitled to cheaper coal than are other consumers. It is regarded as a victory for the consumer as well, who probably never again will be forced to pay the only profit which was earned by the producer of coal.

The reduction of 10c. in the official price was made with the thought that the elimination of assigned cars would result in a saving in operating costs. Issue is taken with this conclusion, however, from the fact that average costs are bound to remain the same. The reduction, however, will not be noticed at mines where the car shortage is not unreasonable. The National Coal Association had expressed the opinion to Dr. Garfield, prior to the agreement, that a reduction of 5c. in the price would be warranted.

The reduction in price will fall heaviest in Alabama, in all states west of the Mississippi, in southwestern Virginia and in certain other restricted fields where production costs already were close to the maximum price allowed. The new price took effect at 7 a.m. May 25. The official order reads as follows:

The United States Fuel Administrator, acting under authority of an executive order of the President dated Aug. 23, 1917, appointing said administrator and of subsequent executive orders and in furtherance of said orders and of the Act of Congress therein referred to and approved Aug. 10, 1917—Hereby orders and directs that all prices for bituminous coal f.o.b. mines in the coal-producing districts throughout the United States fixed by the said executive order of the President, dated Aug. 21, 1917, and subsequent orders of the United States Fuel Administrator and in effect at 7 a. m. on the 25th day of May, 1918, shall be and the same hereby are reduced as to all shipments made after 7 a. m. on the 25th day of May, 1918, by the sum of 10c. for each net ton of 2000 pounds.

This order shall in no way affect the increase contained in the executive order of the President, dated Oct. 27, 1917, adding the sum of 45c. to the prices fixed for bituminous coal under the terms and provisions set forth in said last-mentioned order.

The order was accompanied by the following official statement:

The reduction will mean an annual saving to consumers of a sum estimated by the Fuel Administration at $60,000,000. The President has directed that the railroads pay the Government price for coal. The increased cost of railroad fuel thereby occasioned is also estimated at $60,000,000 per annum. The reduction of 10c. per ton on all coal will, however, reduce the net increased cost to the railroads from $60,000,000 per annum to $45,000,000 per annum. Under the President's plan, the railroads will furnish cars to all coal mines alike, without discrimination except as dictated by the prior requirements of the railroads for operating purposes and the needs of domestic consumers and of the war.

Under the present war demands, the maximum output of every mine working at full time would still be insufficient to meet the country's coal needs. The principle of equal car supply has accordingly been adopted so as to make for as steady an operation as possible of all properties, and for continuous employment of men, thus making for maximum output.

The introduction of the principle of even car supply will reduce the general average overhead of mine operation, and thereby justifies the Administration in putting out a price reduction order. It is understood that the mine prices thus fixed will remain undisturbed until the United States Fuel Administrator has before him the cost returns for the twelve months ending Aug. 31, 1918. The returns thus far in are being carefully studied by Fuel Administration accountants and engineers with a view to making the utmost saving to the public that is consistent with a maximum production of coal.

The order issued will have no effect on the price of anthracite coal, which forms the bulk of the domestic consumption fuel in the eastern part of the country.

Consumers of bituminous coal who have already entered their orders for the year's coal supply, but whose coal has not yet been delivered, will, of course, receive their supplies at the reduced price effective tomorrow. This price applies to all coal which leaves the mines after 7 a. m., May 25, no matter how long the order for the delivery of the coal has been standing.

Coal delivered after 7 a. m., May 25, under contracts which have been entered into since Dec. 29, 1917, will be billed at the new price. Under the regulation of the Fuel Administration all such contracts call for the delivery of coal at the Government price effective at the time of delivery.

Increased Freight Rates on Coal and Coke

The full text of section No. 2 of General Order No. 28 of the United States Railroad Administration, which provides for the increase in freight rates having to do with coal, coke and ores, is as follows:

SECTION 2—COMMODITY RATES, DOMESTIC

A. Interstate commodity rates on the following articles in carloads shall be increased by the amounts set opposite each.

Commodities—Coal: Where rate is nothing to 49c. per ton, 15c. per net ton of 2000 lb.; where rate is 50 to 99c.

per ton, 20c. per net ton of 2000 lb.; where rate is $1 to $1.99 per ton, 30c. per net ton of 2000 lb.; where rate is $2 to $2.99 per ton, 40c. per net ton of 2000 lb.; where rate is $3 or higher per ton, 50c. per net ton of 2000 pounds.

Where rates have not been increased since June 1, 1917, the increase to be made now shall be determined by first adding to the present rate fifteen (15) cents per ton, net or gross, as rated, or if an increase of less than fifteen (15) cents per ton, net or gross, as rated, has been made since that date, then by first adding to the present rates the difference between the amount of that increase and fifteen (15) cents per ton, net or gross, as rated, and to the amounts so constructed the above increases shall now be added.

These rates from producing points or to destinations have been based on fixed differentials in cents per ton, such differentials to be maintained, the increase to be figured on the highest rated point or group.

Coke: Where rate is nothing to 49c. per ton, 15c. per net ton of 2000 lb.; where rate is 50 to 99c. per ton, 25c. per net ton of 2000 lb.; where rate is $1 to $1.99 per ton, 40c. per net ton of 2000 lb.; where rate is $2 to $2.99 per ton, 60c. per net ton of 2000 lb.; where rate is $3 or higher per ton, 75c. per net ton of 2000 pounds.

Where rates have not been increased since June 1, 1917, the increase to be made now shall be determined by first adding to the present rate fifteen (15) cents per ton, net or gross as rated, or if an increase of less than fifteen (15) cents per ton, net or gross as rated, has been made since that date, then by first adding to the present rate the difference between the amount of that increase and fifteen (15) cents per ton, net or gross as rated, and to the rates so constructed the above increases shall now be added.

Where rates for producing points or to destinations have been based on fixed differentials in cents per ton, such differentials to be maintained, the increase to be figured on the highest rated point or group.

Ores, Iron: Thirty cents per net ton of 2000 lb., except that no increase shall be made in rates on ex Lake ore that has paid one increased rail rate before reaching lake vessel.

Restricts Opening of New Mines

No new coal mines are to be opened in the future until the proposition has received careful scrutiny on the part of the Fuel Administration. It is pointed out that coal is not produced commercially until it is loaded into railroad cars at the tipple. The Fuel Administration is unwilling to approve of the opening of new mines even when labor is abundant, if it appears to the Railroad Administration that it is impossible or inexpedient to furnish the necessary railroad facilities. The procedure in each case where it is desired to open a new mine is as follows:

1. All applications for the development of new mines shall be taken up in the first instance with the railroad upon which the connection is desired, full information in regard to the proposed operation accompanying the application. Four copies of applications and papers are to be filed.

2. Three copies of the application and accompanying papers will be forwarded to the Regional Director for his approval or disapproval.

3. The Regional Director will forward two copies of the application and papers with his approval or disapproval to the Director, Division of Transportation, United States Railroad Administration.

4. The Director, Division of Transportation, United States Railroad Administration, will submit one copy of the application and papers with the recommendation of the Regional Director to the United States Fuel Administrator.

5. Representatives of the United States Railroad Administration and of the United States Fuel Administration will, thereupon, agree upon the approval or disapproval, and a single notice of the disposal of the case indicating joint consideration and action, will be sent to the applicant through the office in which the application originated.

Weekly Production Statistics

Bituminous coal production during five days of the week ended May 18 exceeded the 12,000,000-ton rate. A heavy falling off in production on Saturday of that week, however, pulled the figure down to 11,732,000 tons, which was slightly below the performance of the week which preceded. Whether the cause for such a decided falling off on the final day of the week was brought about by lack of railroad cars or by the failure of labor to put in a full day Saturday has not been learned at this writing, but it is regarded as probable that these two factors were mainly responsible. The week which ended May 18 was the first in which there was no car shortage in the Pocahontas and Connellsville districts. Telegraphic advices concerning the week ended May 25 indicate that the performance will be slightly under that of the preceding week.

Anthracite forwardings for the week under review were 41,011 cars, the best showing that has been made in many weeks and an increase of 6 per cent. over forwardings of the week ended May 11.

Beehive-coke production for the week ended May 18 was 678,000 tons, a decided trend upward as compared with the week preceding. Byproduct coke production was 485,076 tons, which is practically the rate of production which has been maintained for several weeks. The industry is being operated at 90 per cent. of full-time capacity. This compares with 69.2 per cent. for beehive operations in the Connellsville and adjacent regions.

The estimates referred to above are those of C. E. Lesher, the geologist in charge of coal statistics for the United States Geological Survey.

To Stimulate Use of Lignites in Northwest

The oil land leasing bill, which includes in its provisions coal, phosphate and sodium-bearing lands, passed the House of Representatives last week without the necessity of a roll call. The friends of the bill believe that it will stimulate the development of coal and lignite on public lands. During the course of the consideration of the bill Representative Norton, of North Dakota, stated that he had been given reasonable assurance that an experiment station of the Bureau of Mines is to be established in the Northwest which will be devoted exclusively to the consideration of problems looking to a more extended utilization of lignites.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The labor conditions were never better than they are today, for the railroads are giving improved service. There is no crop now to move, there are no winter obstacles and no trouble with floods; consequently the railroads are enabled to give a maximum car supply. In the week ending May 4, the railroads in the bituminous region had a car shortage of only 13.1 per cent. and on the week ending May 11, a shortage of only 11.2 per cent. In both periods the mines worked over three-quarters full time.

Unfortunately labor shortage and strikes caused a loss in operation of 5.4 per cent. In some sections the men will not work steadily, largely because they are not sufficiently and satisfactorily appealed to. Public meetings and posters are needed in every place to encourage the workman to do his utmost every day. It may almost be justifiably asserted that we have no posters urging steady work, day by day, and such few as are available are not posted. As the railroads do their duty more thoroughly the opportunity of the operators to urge steady work will be greatly extended and even now a campaign is badly needed in some sections.

ALABAMA MINERS CANNOT BLAME RAILROADS

Notably among these sections is the state of Alabama with a car shortage of only 0.5 and 0.3 per cent. in the two weeks under consideration. The labor shortage was far more important than the car shortage, namely, 8.3 and 8.8 per cent., respectively, and the strikes added 0.4 and 0.3 per cent. This is a bad showing for the mine forces. The miners owe it to the nation to work so steadily that they will never fail to fill the cars afforded them.

At this time of year the car supply is at its best, but the labor supply is normally at its worst. All the farmer miners are leaving the pick for the plowshare. The mines begin to fill up again in the winter, just at the time when the railroads are least able to haul freight and when transportation is cluttered by the product farmed by the miners and others, especially the others, during the summer. The farmer has some idle days in the warm weather but he does not feel as keen about his mining work so long as there is any need during any given week to work on the farm.

The situation in the Broad Top region is unchanged except that the decrease in the price of coal only makes the operators of that region less ready to make wage concessions. Unsupported by public opinion, the Fuel Administration and the union, the mine workers along the Huntingdon and Broad Top R.R. do not seem to have any great chance of winning their strike.

COMPARED WITH SOLDIER'S, MINER'S BIT IS SMALL

Philip Murray, the president of the Pittsburgh district (No. 5), at a meeting held at Bentleyville, Penn., denounced the miners who are unwilling to work because they can make a good living when working short time. Murray said "If the soldiers can shed their blood on the battlefields of Europe the miners can work. When the Government and the coal operators agreed to give the miners the greatest increase of wages ever known to organized labor the union leaders gave their solemn promise that the miners would work and insure the Government 100 per cent. production during the war. I beg, I plead with you to get to work and make good your promises to your employers."

United States Circuit Court Judge Joseph Buffington also addressed the meeting, scoring those who would not work eight hours six days a week. He said, "Any man who is able to work and won't work in these times is putting in that much time for the Kaiser and the Potsdam gang. There is no room in America for idlers or boozers."

In a well-reasoned editorial, the *American Coal Miner* explains why it is necessary that adequate prices be paid to the operator if peace in the labor field is to be attained. It shows admirably the reason for President Farrington's statement, reprinted in last week's *Coal Age*, page 978, that the union would feel unfriendly toward cut-price operators. However, it was not the purpose of the editorialist to discuss Farrington's letter, but to explain why the railroads should not be granted a drastic price reduction. The editorial says:

"Those conversant with mining know well that when operators are operating on scant margins cases of dispute about the payment for yardage, deadwork, setting props, laying rails, etc., multiply, because the mine foreman and superintendents are urged to work for the lowest possible production costs. When payment is demanded for these extras for mine labor by miners, the bosses, realizing the small margin under which they are operating, hold back and endeavor to drive bargains.

"Settlements that could be easily made between mine committees and mine bosses under a fair margin are delayed, carried up to joint boards, arbitrators and commissions, all of which causes unrest, reduces the efficiency of the men directly involved and promotes a general bitterness among the working force."

HOPKINS' MINERS GIVE RED CROSS A DAY'S WORK

The mine workers and coal companies of Hopkins County in western Kentucky contributed their entire output to the American Red Cross on Monday, May 27. The St. Bernard Coal Mining Co., with offices at Earlington, Ky., which was one of the companies in this generous dedication, operates 10 mines and employs about 3000 mine workers. There are four mines at Madisonville, Ky., that employ more than 1000 men.

In British Columbia, Canada, the Crow's Nest Pass Coal Co., Ltd., and other operating concerns in the Crowsnest region have granted a further increase of 20c. per day to their men. This increase will add to the payroll of the larger company mentioned $10,000 a month.

Not Patriotism but Trade Restriction

According to Attorney General Brundage of Illinois, the high wages paid in the mines were the indirect cause of the lynching of Robert P. Prager by a mob at Collinsville, Ill. He says that the state will demand the death penalty for the lynchers at their forthcoming trial.

"The entire trouble," says the attorney general, "grew out of Prager's desire to become a miner in Illinois. He had been working in St. Louis but figured that he could make more money in the mines. Consequently he moved to Illinois and applied for a certificate as a first-class miner. His application for this kind of a certificate was questioned by the officials of the miners' local on the ground that he had not worked four years at the business. Prager had the papers to bear out his statement and brought them forth when the officials called for them. Several days later he was paraded through the streets with a flag wrapped about him, probably because he had made the statement that he had worked four years in the mines in Germany. The parade, however, was in the nature of a joke and everyone was good natured about it. Later it took a more serious turn and ended with the hanging. Absolutely nothing was developed by the investigation to show that Prager was in any way unpatriotic."

The job of juryman in the Prager case is not popular. It was necessary to send deputy sheriffs throughout the county to secure suitable talesmen. The card system of drawing veniremen was discarded. On May 14 68 veniremen had been examined and not one had received the approval of both prosecution and defense, though three men had been tentatively accepted by the state. The accused appeared at court patriotically and conspicuously decked with the national colors.

The tedious process of getting a jury to try the men was little accelerated during the week following. Only eight men were finally accepted.

The greater part of the week was spent in an effort to get the other four. Court adjourned to last Monday, however, without the jury having been completed. Almost 650 talesmen had been examined. In adjourning court Friday, May 24, Judge Bernreuter congratulated the eight men and said he was proud there were eight men in the community who were willing to uphold the honor of the United States. He scored others who, he said, had read about the case after being called, for the purpose of arriving at an opinion and disqualifying themselves for service.

The general disposition has been to excuse farmers from the jury because of the paramount needs of the farm, and miners are probably not acceptable to the state's attorneys because they are apt to be friendly to those who are accused of Prager's lynching. It is hard to find a jury in a farming and mining community when there are reasons for not accepting both farmers and miners. However, on May 27 a jury was finally secured, and the trial commenced.

Superstition Closes Illinois Mine

One night last week, Charles Sartorius, the watchman at the Peabody mine near Kincaid, Ill., dreamed that someone was stealing the mine's supply of powder. When he awoke he investigated and sure enough there was no powder where he thought there should be some. Furthermore, he discovered at the pit mouth a skull and crossbones crudely drawn on a sheet of paper.

The story got around, and the next day most of the 700 miners stayed at home. They reasoned that the dream, the stolen powder and the skull and crossbones pointed to a plot to blow up the mine. An investigation showed that no powder had been stolen and that the skull and crossbones had been drawn by school boys. Slowly the miners recovered from their alarm and returned to work.

Should "Targets" Be Hired?

Perhaps it is better to define a "target" before going further, for the reader may not have heard the expression used regarding an employee. A "target" is a man who is, or appears likely to be, a bad risk because he is subnormal, mentally or physically or both, and therefore does not exercise due care at his work. He is likely to be repeatedly injured or, as Kipling would put it, "frequent deceased."

The Kansas City local of the National Safety Council discussed the question at its meeting on May 7 under the head, "How can the increasing turnover be checked, without keeping, in hazardous jobs, men or women habitually careless?" The question is not an easy one to answer in view of the shortage of labor.

One of the largest plant managers in Kansas City stated that he felt under obligation to accept for employment men whom under ordinary circumstances he would summarily reject. He said that it was not only a necessity to get someone to do the work, if only in a fashion, but it was also an obligation to provide everyone with work in view of the need of the war that our whole man-power be utilized. Many of the manufacturers present at the meeting discussed earnestly the ethics of refusing to employ a subnormal workman who needed the work, but could not be expected to fill the place with due efficiency and perhaps not with safety.

United States As an Employer

Uncle Sam in his capacity as the world's greatest employer is discovering that his workers will not "live by bread alone" and that high wages are not of themselves a sufficient inducement to hold men to their work. He is discovering that men are social beings and that employees must have certain social and community facilities if the daily job is to content them.

In a certain district two great munition projects are located. One of them, lacking almost everything in the way of recreational and welfare facilities, has had a labor turnover of many hundred per cent. The other with identically the same work and the same rates of pay has had no such turnover. The reason evidently is that the latter plant is located on the edge of a city whose social facilities while meager have yet been sufficient to bring into the lives of the men that social contact with one another for which we all instinctively crave.

At nearly all Government projects the wherewithal for recreation and social welfare is being put under way. Community huts are being erected where men may meet and play their games, where they may smoke and spin yarns and build that invisible, intangible something known as esprit-de-corps. Moving pictures are being provided and are attracting increasingly great audiences, and it is an interesting sidelight that the most popular pictures are of current events and not of the slapstick variety.

Reading rooms with books and magazines are being furnished for those studiously inclined. Baseball diamonds and tennis courts and up-to-date equipment are being built and baseball leagues organized. Lectures and concerts are to be provided from time to time and bands are being formed and equipped. Y. M. C. A. men are in charge in some of the large projects and ordnance welfare executives are being provided at others. Health conditions are being improved and at one project the U. S. Public Health Service is undertaking a clean-up resembling that so efficiently inaugurated at Panama.

In short, Uncle Sam is following the example of other great employers of labor and undertaking to keep his men sound in mind and body and watching with a jealous eye their comfort, convenience and happiness.

Another interesting phase of work which is being undertaken by the Ordnance Department through the Community Organization Branch of its Industrial Service Section is to work hand in hand with groups of citizens in those cities containing factories producing munitions, to eliminate those community conditions which may be adversely affecting the welfare of labor.

Many of these cities are so congested by war workers that they are unable to furnish community facilities for the newcomers. Part of the program to be worked out in such cities by the Community Organization Branch is as follows:

"Campaign of patriotic education to impress upon workers that they are the second line of defense and that their efforts are absolutely essential to the safety of the men in France and to the winning of the war. Formation of housing companies and of building-and-loan associations and the encouragement of home-building by individuals. Extension of trolley tracks to new districts and increased service. Extension of water, sewer, gas and electric service to the new housing districts. Ordinances to prevent the exploitation of the workers. Nearby farmers encouraged to grow produce, and public markets installed for producer and consumer. Provision of facilities for plowing and harrowing home gardens. Installation of branch libraries for convenient use of new workers and their families. Erection of community center "huts" with moving pictures, supervised dances, concerts, lectures, etc. Increased school facilities for children of new workers and night school during winter months for adults. Control of alcohol and social evils, and education of workers by medical specialists. Complete Americanization movement for naturalization of aliens, and instruction in history and citizenship. Education of workers, their families and especially the children to the need for thrift, and the complete utilization of the workers' time.

Canada's Difficult Coal Problem

CONDITIONS have been so vastly changed by the war that nations which formerly wished to exclude foreign products are now most anxious to receive them and are satisfied if they receive all that can well be spared. Canada, which regretted the fact that it had to buy coal from the United States, is now troubled because it seems probable that we will not have enough for ourselves to do our full part in supplying her.

Nations are dependent one on another. Whenever all tariffs are revoked they buy of one another just as if there were no lines of nationality. It is well for Canada to zone itself with the United States in peace and in war, contiguous areas in both dealing with one another to their mutual advantage without considerations of national lines. That section should perform the service that can do it with the least labor. If with the least labor the United States coal can reach Ontario, then Ontario is a market for United States coal. On the other hand if Boston can be better reached from Canada, then the Canadian coal has the better right to purchase.

Most nations today are worrying more that they won't be shipped enough than that they will get too much. In our great need we do not look over closely at the source. The "Made in America" cry has gone by the board with "Made in Canada" and "Made in Great Britain." What we want we must have, no matter whence it comes.

Could we believe in 1914 that the representative of the Canadian government would say in 1918 that "in the regulation of the supply of American coal to meet this year's requirements of both the United States and Canada the United States authorities had generously provided that there would be no discrimination against Canada, which in this respect would be treated as if it was part of the Union"? "This decision," says the Canadian Mining Institute Bulletin, "is further proof of the close and fraternal relationship that exists between the two countries; but if for no other reason than a desire to impose as little as possible on the goodwill of our neighbors, when such imposition may mean hardship to them or the impeding of their war efforts, our demands on them for coal should be limited strictly to imperative needs that cannot otherwise be satisfied."

This statement does not accord with the belief that every nation is ringed about with economic enemies. When will we learn that we can only receive satisfactory service by accepting it from those who are qualified by nature and propinquity to render such service? May the sentiments fostered by the war in our neighbor and ourselves last long after the war, and let the man who in the United States burns Canadian coal be as well satisfied as he would be if he knew the fuel came from a neighboring state.

No nation can become wealthy by buying material made under disadvantages or produced in a remote location, even though produced on the national terrain and hauled on the nation's railroads. It must buy where production is easy and the haulage cost is light. The world needs zoning, but in the planning of such zones the national lines will be of continually decreasing importance. The buyer and the seller are both benefited by trade, as we soon learn to realize when the seller refuses to sell. It is a relic of an old world this idea that the seller should carry his hat in his hand. He needs the buyer, it is true, but at times not nearly so much as the buyer needs him.

Coal, Like War, Waits on Transportation

FOR a long time the main problem of the war has been to determine how the Allies in Europe were to be fed and our armies sustained at the front with our ocean transportation threatened with a complete breakdown by the continued and powerful assaults of the German submarines. The problem is by no means solved even to-day, and the scare we have had has left us with little of the former complacency.

The coal situation is much the same. We have the men, at least to a large extent, and we certainly have the producing facilities for the largest possible demand for coal. We could supply ourselves with all the coal we need and at the same time provide our allies with all the fuel needed to supply their deficiency. With our capacity we might even supply Great Britain with as much coal as it is now producing—if we could only haul it on the railroads and find place for it in the holds of our vessels.

The public has been much comforted by the fact that nearly a billion dollars is to be expended by the Railroad Administration on new equipment and betterment. A billion dollars seems a smaller sum of money than it did a few years ago. But even in days when few used to think in billions we used to spend that billion without really knowing it. A great, big overgrown nation, we did not reckon just what our total expenditures were. We bought in small units. There were many corporations, and most corporations distributed their purchases through the year. Thus a large aggregate tonnage was purchased without it being considered large.

But now the public has its enumerating done for it. The Government is doing its own buying. It does it all at one time in the year, at least, it estimates in that manner, and it does it for all the railroads at once. The public is interested and sympathetic, as it always is in the work of the Government, and it is therefore quite ready to declare that the expenditure planned is stupendous and to anticipate that it is adequate to all the Government needs. It is needful, therefore, that we view the proposed expenditures critically.

The first important need to be met is locomotives. The new order will only add 1½ per cent. to their number, for there are 65,000 locomotives now in use. The new locomotives, however, will be larger in size and greater in power than the average locomotive now in service. They will probably do twice as much work, and for this reason the addition to the tractive ability of the railroads will be approximately 3 per cent. With this "stupendous" program the locomotive equipment would be changed every 33 years. Thus, under such a plan, locomotives of 1885 would just be ready for retirement; and if this percentage of new construction had been followed steadily since 1885, our transportation facilities would either be on the low basis of that year or we would still be using locomotives used during the Civil War.

The car program is more generous. The number ordered is 100,000, representing an increment of 4 per cent. to the 2,500,000 cars now in use. As the cars will be larger than the average now in service, we may say that the increase in capacity will be roughly 5 per cent. With this program we shall prevent a positive reduction in our freight-carrying equipment only by making it last a full 20 years. There will be no increased capacity unless we make the equipment last longer. Advance in the design of railroad equipment will never be rapid with such niggardliness in renewals. Even in the worst years of the railroads the car purchases have been larger. For years, when traffic even seemed to show signs of temporary decline, the railroads purchased more than the 5 per cent. of car equipment that is now quite generally extolled as amazing.

The *Railway Review* says that "for more than six years they [the railroads] have averaged car orders 50 per cent. greater than the 'control' has now put out"; and again its says, "As a mere matter of fact the Government is ordering two-thirds as much equipment as the railroads did in the year of their greatest distress under oppression, and less than half as much as they have averaged through the years of feast and famine."

As another authority points out, the whole billion dollars, or rather the $937,961,318, for that is the real sum, is only 6 per cent. of the existing capital investment in stations, terminals, roadway and equipment. Furthermore, the Associated Press dispatches lead us to doubt whether this 6 per cent. will be spent in adding to railroad facilities. "The figures," says the report of that agency of the press, "disclose Director General McAdoo's determination to let the railroads make many improvements which they had neglected during the last three years, through permitting tracks to run down and postponing all possible projects requiring big expenditures of capital." Evidently, if they disclose this purpose they do not offer hope that much of the necessary new work will be done.

In 1907 J. J. Hill advocated that at least $1,100,000,000 be spent annually for new construction and improvements, in order that the transportation interests might be kept abreast with industrial progress. Today $2,000,000,000 would scarcely do what $1,100,000,000 would have done in 1907.

Of course, Mr. Hill had in view construction such as could not patriotically be advocated during the war. This is conceded. Another concession may profitably be made, which is that Director General McAdoo probably believes that any program larger than he has written could not well be enacted in the twelve months of a single year with the world at war. He may well be justified in his decisions. Nevertheless, it is needful that the public generally, and especially the suffering coal industry, realize the narrowness of the program the Railroad Administration has, rightly or wrongly, decided to adopt.

Give the Hat-Boy His Tip

THE recent lowering of bituminous coal prices one dime per ton will be viewed quite variously; but, however viewed, the coal companies will loyally accept it. Some will feel it is hard to have to give a dime to the railroads and the public in order to secure that justice which is everybody's natural right. The dime will look like the *douceur* that we give to the hat-check boy. It will be said that the coal industry will be compelled to pay about $60,000,000 a year to get justice from the railroads. They cannot give adequate service, of course, but the service they give from now on will be evenly distributed. Pay your tip or the service rendered the coal industry will, in the future, be uncertain and irregular.

On the other hand, it must be admitted that the United States Fuel Administration in fixing coal prices may have visualized the possibility that the railroads, even though federalized would, as in the past, have "ways that are dark and tricks that are vain" and may have sought therefore to protect the coal companies by a degree of liberality in the fixing of prices. Or to put it more exactly, the figures of operating cost furnished to the United States Fuel Administration were based on actual and not on ideal working conditions, and the Fuel Administration has felt itself justified in believing that a little steadier work as an outcome of greater equity and more efficiency in railroad operation would result in reducing those costs.

The quarrel is at an end. The Railroad Administration promises to be good. If it starts buying coal as fast as coal may be obtained and tries no more shenanigans we can forget its past delinquencies, for the coal trade also has some things it would like to have forgotten. There is that little matter of dirty coal, for instance.

White Goes on Labor Policy Board

THE United States Fuel Administrator announced, May 28, that John P. White, the labor advisor to the Administration, was appointed representative of the Administration on the Labor Policy Board of which Felix Frankfurter is chairman. We wonder what the attitude of the industry would have been to such an appointment before the war and before it had its recent opportunity to know and appreciate Mr. White. It would certainly have said that at least a man like Rembrandt Peale should be added to provide a balance.

But since the war commenced Mr. White has shown clear evidence of his saneness of outlook and uprightness of purpose. Despite the fact that it cannot be denied that he represents only labor, he is sure to be regarded not unfavorably by capital. The policies he will advocate will doubtless be those he has elaborated with Rembrandt Peale and the Fuel Administration.

DISCUSSION BY READERS

Success in Mine Management

Letter No. 2—Reading the excellent article of W. W. Beddow, *Coal Age*, Apr. 27, p. 778, again calls up the question of what constitutes a successful manager of mines. Attention was first drawn to this matter by R. W. Lightburn in his letter, Apr. 13, p. 707.

As someone has already pointed out, the mine official who succeeds in holding his job and is successful in producing results is a man who is bigger than his job. While there are many thoroughly capable mine officials, there are many others who fail in a very vital point.

Success in management always involves the providing of suitable equipment that will enable the men to work efficiently and which will insure the production of the required output at a minimum cost. The failure to do this is common not only to the higher officials, but to those whose duties bring them into intimate contact with the daily operation of the mine. The principles that concern success apply equally to the higher officials and to their subordinates.

From Mine Foreman to Superintendent

One difference that is plainly noticeable to the close observer is the change that comes over the average mine official as he rises in the company and assumes a higher office. In his new position, a superintendent is not as anxious to secure improved equipment or undertake certain improvements in the mine that, as foreman, he was very anxious to secure.

Every foreman has an ambition to be progressive and is constantly recommending the most up-to-date equipment possible, because he realizes that the work of mining coal and hauling it to the shaft bottom can be greatly advanced by the employment of better methods and improved equipment.

As superintendent, however, the man's ideas seem to have undergone a change. He now views things from a different standpoint and is not so anxious to increase the cost-sheet by the purchase of new equipment or by undertaking the improvements recommended by his foreman. He appears to have forgotten his previous experiences in the mine, when, as foreman, he saw the need of these things, and falls automatically into the well-beaten path of his predecessor in office.

To the average mine foreman who is anxious for advancement, good equipment is a necessity; but with many superintendents, general superintendents and managers, any old equipment is good enough, provided the mine cars can be kept bumping over the rails, the locomotives continue to haul a fair tonnage, and the mine is not compelled to shut down too often for repairs. As long as the mine can be kept running fairly well, and their excuses for occasional failures are accepted, these higher officials are completely satisfied.

Many men fail to realize how much greater things they could accomplish by retaining the same progressive spirit that animated them when they occupied a lower position in the scale. I would not like to style this disposition of the higher official as a growing stinginess. I am inclined rather to explain it by saying that, in their higher position, the said officials are farther removed from observing daily the actual necessities of the work underground.

Managers are more concerned with the appearance of the cost-sheet and often forget that a low cost of operation can only be maintained by devoting a reasonable amount to improvements in methods and equipment. The foreman is, as we say, up against hard facts. He is pressed for a larger production at a reduced cost, while he is denied many things that are essential in order that he may make a good showing in the mine.

In reading the different articles in *Coal Age* that bear on this subject, I have been impressed with the fact that the majority of the men in charge of smaller operations do not have the *vision* that marks men for the highest attainments. This will even apply to many men in charge of larger operations.

In this connection, let me say that it would be a fine thing if some of the practical readers of *Coal Age*, who are in intimate touch with mining needs, would discuss the need of broader vision in securing a greater production of coal at a minimum cost of operation.

Let us see if we can ascertain why some men are more farsighted than others whom they have outdistanced in the race and have thus proved that their ideas are well worth while. Believing that these thoughts are of vital importance to successful mine management, I hope for a discussion that will broaden our vision and give us greater success in the management of mines.

Loading and Shipping Clean Coal

Letter No. 7—Much has been written regarding the shipping of dirty coal and showing the large loss to the consumer, due to being compelled to burn coal containing a high percentage of refuse. This loss occurs not only from the low heat value of the mixed coal and refuse, but because of the additional expense of disposing of the large quantity of ash, to say nothing of the freight charges paid for such material.

A difference of opinion seems to exist, on the part of writers, in regard to who is responsible for the loading of this refuse with the coal. A few blame the mining companies for a laxity of discipline, while many believe that the miners are the parties most to blame. It is probable that both the operators and the miners contribute their share toward the difficulty.

We all know that the miner can increase his earning capacity by not taking the time necessary to remove the bony coal and slate. He not only gains in time and is able to load more cars, but increases his daily tonnage by the weight of refuse he loads with his coal.

Many of the coal companies allow this practice to proceed and offer little restraint, fearing the loss of good miners if they are too strict in their requirements in the mine. A few operators may even consider that the shipment of dirty coal will command the same price in the market, at the present time. They also realize that less experienced miners can be employed where the quality of the coal loaded is not a matter of so much importance.

There is an old saying that "Every cloud has a silver lining." The "silver lining," in this case, may prove to be the education of consumers, who learn how to burn lower grades of coal than that to which they have been accustomed. While this may require practice in firing and the installment, at times, of equipment better adapted to burn coal of an inferior quality, it will have the beneficial effect of conserving the better grades of coal and utilizing that of poorer quality.

Appearance No Indication of Quality

In the past, much prejudice has existed against coal that did not present a good appearance, though being of a fair quality. Some consumers would even refuse to give a rusty or muddy-appearing coal a trial, and looked askance at the bright colored peacock coal.

In Maryland, for many years, the only coal accepted by large plants was the best portion of the Pittsburgh or "Big Vein." But, as this seam approached exhaustion, these large consumers became less particular and soon discovered that all of the seam was of good quality. Later, they were glad to get both bottom coal and peacock coal, and, more recently, the same plants have been altered to burn outcrop coal, and many have been willing to take coal from other seams.

In the great demand for coal last winter, much of the extreme outcrop coal was stripped and loaded for market. Recently, strange as it may seem, the chemist of a large public-service corporation, in an eastern city, stated that the quality of this outcrop coal was remarkable. He said that, to see some of it on the railroad cars, one would think that it would be more likely to extinguish a fire than to maintain combustion.

In working the lower Kittanning seam, in West Virginia, several years ago, it became necessary to stop all places where the coal looked rusty or, as frequently happened, was partly coated with a thin fireclay mud. If but a small quantity of such coal reached the car, a complaint might follow or the shipment even be refused.

A recent analysis of this rusty and muddy coal, however, showed that the complaint was unnecessary, as the supposed low quality of the coal was imaginary and not real. Three types of this coal were analyzed; "A" is an average of fifteen analyses of glossy black coal, as usually shipped; "B" is an average of five analyses of muddy coal; and "C" an average of five analyses of rusty coal. They are as follows:

	A	B	C
Moisture	0.82	2.14	1.99
Vol. carbon	21.86	23.66	23.68
Fixed carbon	70.08	67.88	66.90
Ash	7.24	6.32	7.44
Sulphur	1.10	0.74	0.85

It will be observed that with the exception of a varying moisture content, the difference in quality of these coals would hardly be sufficient to justify a complaint being registered when a small quantity was found in a shipment.

In closing, permit me to suggest that, while the loading and shipping of impure coal is to be deplored, there will result eventually some compensation, should consumers learn to judge a coal by its actual quality, as determined by analysis, and not be prejudiced by the appearance.

J. A. Smith.

Albert, W. Va.

Letter No. 8—I am of the same opinion as W. H. Noone, who states in his letter, *Coal Age*, Apr. 20, p. 754, that "the shipping of slate and rock for coal is nothing more or less than an act of treason." Any operator found guilty of shipping an inferior quality of coal to the Government, for use on shipboard or in munitions factories, at this time, should be regarded as a traitor and his mine taken over by the Government.

I am inclined to have more sympathy with the miner when the conditions in his working place make it difficult for him to avoid loading more or less of bone and other impurities with his coal. Further, the miner is often obliged to speed up in loading his coal, so as to keep the drivers running, which gives the miner little time for a close inspection of what he loads. I have always claimed that the cleaning of the coal could be better done by daylight than in the mine where the miner is often deceived by the uncertain light of his lamp.

Coal Better Cleaned on the Surface

In order to clean the coal properly, at the surface, it would be necessary to install a suitable picking table, onto which the coal could be dumped as it comes from the mine. A sufficient number of boys must then be employed to pick out the bone and slate from the coal as it passes them on this table. At some mines, the miners have agreed to allow a deduction of 10 per cent., or 20 lb. to the ton of coal sent out of the mine, to pay for the employment of slate and rock pickers. They have also agreed to let the company dock them 100 lb. when the rock and slate in a single car exceeds 10 lb.

This method, however, has not proven generally satisfactory to the miners, because of the opportunity it offers for dishonesty on the part of the company, unless a checkweighman is employed. Where there is no checkweighman, the miners are apt to say "We are paying for the rock, so let her go."

In my opinion, it would be an advantage to appoint a coal inspector at each mine, whose duty it would be to visit every working place in the mine and instruct the men showing them the difference between the coal and bone and rock or slate. Let him secure some of the bone, slate and rock that have been picked from the coal sent out of the mine, and warn the miners by telling them what injury they are doing the mine when they load out such refuse. He should show them that they are running the risk of a shutdown of the mine by reason of the shipment of coal of an inferior quality.

When miners continue to load out rock and slate that should have been easily detected in the mine, it would be better to get rid of them without further delay. At

the same time, the men who load clean coal should be informed that their work is appreciated. Such a system has been followed at the mine where I am employed and I understand that the traveling coal inspector has stated that the coal coming from this mine is of better quality than for years before.

It is the patriotic duty of the miner who mines the coal, the operator who ships it to market, and the dealer who makes the final delivery to the consumer, to see that the coal is clean and of good quality. The consumer, on his part, must not be too severe when he finds a shipment to contain some impurities. He should notify the dealer or the company of that fact, making due allowance for the urgency of the present time. We must all make large sacrifices in the great cause for which we are striving; namely, that the earth shall be a better place in which to live.

Farr, Colo. ROBERT A. MARSHALL.

Gathering Motors

Letter No. 4—I have been an interested reader of the letter by "Motorman," who describes in some detail the different types of gathering motors that have been used in mines, *Coal Age*, Apr. 27, p. 800. Although the letter draws attention to several good points, I am compelled to differ with the writer in his view regarding the relative value of the combined trolley and storage-battery locomotive, which he seems to regard as a revolutionary step forward in gathering-motor practice.

There is hardly a question but that almost any form of storage-battery locomotive is an improvement over the old cable-and-reel motor. But, since the storage-battery locomotive has come to be an accomplished fact, by reason of its mechanical perfection and the durability of its batteries, let me ask, Why is it necessary to add the trolley attachment?

In the large number of mines that have installed storage-battery locomotives for gathering purposes, they have been found to perform every function of which the old cable-and-reel motor was capable. In all cases, the battery locomotive has given good satisfaction and performed the required work, except where the machine has been compelled to haul poorly built mine cars. From every standpoint, this type of gathering motor has proved efficient and economical.

The most successful installation of storage-battery locomotives that I call to mind at present is in a mine equipped with high-grade, roller-bearing mine cars. In an exhaustive test, it was demonstrated that the drawbar pull necessary to haul mine cars equipped with this type of bearing is reduced by 50 or 60 per cent.

No Need To Boost Batteries

We learn, also, that where storage-battery locomotives are used to haul roller-bearing mine cars, no time is necessary for the boosting of the batteries, as suggested by "Motorman" in the letter to which I have referred. When hauling these cars, the batteries have been found to perform their function with complete satisfaction throughout the entire shift, and the charging is done entirely at night.

It is true, as "Motorman" has stated, that when the charge of a storage-battery locomotive is about half exhausted, the drop is much more rapid in the latter half than the first half of the shift. However, no serious depletion of the charge of the batteries will occur if they are not subjected to the heavy drain caused by starting a trip of plain-bearing cars.

Cars equipped with roller bearings, it has been found, can be started with only 40 per cent. of the power required to start plain-bearing cars, and there is far less drain on the batteries from this cause. Stated in another way, the average plain-bearing car is two and a half times as difficult to start as the roller-bearing car of the same size and under the same conditions.

Track Resistance Greater Hauling Empties

While speaking of hauling trips of mine cars equipped with different types of bearings, kindly permit me to mention one fact that is not generally known; or, if known, is often overlooked when laying out the main haulage road in a mine. Engineers ordinarily give the main road a grade in favor of the loaded cars, but often fail to take into account the fact that if the cars are equipped with plain bearings the track resistance of the empty trip is increased by 40 per cent. over that of the loaded trip. It is interesting to know that if the cars are equipped with the best type of roller bearings, the track resistance for the empty trip is only 15 per cent. greater that that for the loaded trip.

These facts are of vital importance whenever a storage-battery locomotive is used on the main haulage road. As is well known, it frequently becomes necessary to start the empty trip on the upgrade where it has been halted by some obstruction on the track. These considerations should all be taken into account in estimating on mine haulage conditions.

As is generally believed, the success or failure of any gathering haul depends almost entirely on the condition of the track, the kind of mine cars and locomotives used, and the knowledge and skill of the motorman. In speaking with a prominent mining man, only a few days ago, he expressed the opinion that it will not be long before every mine manager, having an eye for the future, will insist on the installation of roller-bearing mine cars and storage-battery locomotives.

Pittsburgh, Penn. STORAGE BATTERY.

Observation of Sun for Latitude

Letter No. 2—Kindly permit me to draw attention to what seems to be the omission of a line, or a few words, from the last sentence of the letter of Prof. Howard Eckfeldt, *Coal Age*, May 11, p. 891. Speaking of "parallax," the statement reads, "Allowance must be made for the semi-diameter of the sun; but, as the resulting parallax amounts to but a few seconds of arc, it is usually ignored in this observation."

It is well known that the semi-diameter of the sun, as observed from the earth, covers an angle of about 16 min. Professor Eckfeldt has just stated that allowance must be made for this when observing the disk of the sun instead of its center. It is evident, therefore, that the allusion in what follows is the parallax resulting from taking the observation from the surface of the earth instead of its center.

This error of observation amounts to but a few seconds of arc, and, as stated, can usually be ignored.

Parallax, for the sun, never exceeds 8.8 sec. of arc, so that when using a transit whose vertical circle reads only to minutes, this correction is inappreciable. [Our thanks to Professor Callen.—Editor.]

While writing on this subject, permit me to refer to the suggestion made by H. M. K., in his inquiry, *Coal Age*, May 18, p. 943, in regard to constructing a chart that would read to a larger scale than the one designed by J. T. Beard, which appeared in the issue of April 20, p. 733. The suggestion made is that the chart should read to minutes of longitude and half hours of time, etc.

A moment's reflection will convince anyone that the actual longitude of the observer is not the important factor, unless the observer's watch is set on *sun time*. It is customary, however, to use *standard time* when taking an observation; and, this being the case, the change in declination of the sun from Greenwich noon, as tabulated in the Ephemeris, must be reckoned to the longitude's meridian for which the observer's watch is set.

For example, if the watch is set for Eastern time, the observer must reckon his longitude as 75 deg. W. from Greenwich. If his watch is set on Central time, he must estimate the difference of time to longitude 90 deg. W., remembering that the change in declination, from that given in the Ephemeris, depends only on the difference of time between the observer's watch and Greenwich noon.

A. C. CALLEN,
Prof., Mining Engineering,
Morgantown, W. V. West Virginia University.

Safety in Shotfiring in Mines

Letter No. 4—I am much in favor of the employment of shotfirers to charge and fire all shots in mines, instead of leaving this work to be performed by the miners. The shotfirers should be experienced men having the training that will enable them to determine correctly the amount of explosives that must be used to bring down the coal, in any case.

Where miners do this work themselves, the hole is often overcharged, or a frozen cartridge is inserted, which fails to explode and later finds its way into the car and possibly into the furnace. The work of blasting in mines is dangerous, unless it is properly performed by experienced men.

There is another feature to this question, however, that is likewise of importance. Attention has been drawn, in previous letters, to the danger of the presence of enemy-alien miners, employed in our mines, during the progress of the war. To my mind, their presence in the mines is a serious menace. Even though the enemy alien himself may intend no harm, he may have one or more men working near him who have taken a dislike to the man and are only too willing to seize upon the opportunity presented by the war to make trouble for him. They may even go so far as to place dynamite in his car, in order that it may be found and blamed to him as a disloyal act.

In time of peace, the finding of an occasional stick of dynamite in a car of coal would be regarded as an accident or due to carelessness on the part of the miner, who would be reprimanded and cautioned not to let it occur again. In time of war, however, such an occurrence is attributed at once to disloyal intent.

While I wish to be fair to all enemy aliens who are loyal to this country, I feel that there is much risk in letting this class of men work in our mines. It would be better, in my opinion, to employ them at other work that will afford them or others no opportunity of doing a harmful act.

C. MCMANIMAN.
Rawdon, Canada.

First Aid to the Uninjured

Letter No. 6—I have been much impressed in reading the letters that have appeared in *Coal Age* on this subject and cannot resist offering a few comments regarding our attitude toward all first-aid and safety-first work.

A short time ago I was looking over the anthracite mining laws of Pennsylvania and noted with interest the ample provision made for the care of the injured, in Art. 7, which gives in detail the kind of ambulance, stretchers, etc., that must be kept at the mine, in readiness for immediate use in case of accident.

The thought struck me, in this connection, that before the benefit of this wise provision can be fully assured, how important it is to give the necessary instruction to all classes of mine workers, in order to enable them not only to give the necessary first aid to an injured fellow worker; but, more important than all, to impress upon every man this idea of rendering *first aid to the uninjured*, and thus enable them to avoid these accidents.

In the giving of first aid to the injured, it must be remembered that, while the up-to-date motor ambulance is a great improvement over the old-time method of hustling an injured man over a rough road in an old black, springless, unventilated wagon half-filled with straw, and wrapping him for the time in old blankets that are scarcely fit to keep the mule warm that draws the wagon, these improvements will be of little aid unless the attendants understand how to treat the injured man successfully.

Unless a broken leg is first placed in a rigid position between splints, a well-appointed ambulance will not prevent what was originally a simple fracture from being aggravated in a manner that will necessitate the loss of the injured member. Likewise, improved appliances will not prevent a man bleeding to death if his fellow workers do not understand how to control the loss of blood from a severed artery.

OPERATORS AND MINE OFFICIALS, TAKE NOTICE

In the giving of first aid to the uninjured, I want to ask, Do our mine officials realize the importance of giving their men needed instruction in the treatment of possible injuries? Observation shows that, in many cases, because of the lack of foresight and the provision of this needed instruction, many lives have been lost, at our mines, that could have been saved had fellow workers known how to treat the injured ones.

A while ago, while walking one of the streets of Wilkes-Barre, my attention was attracted to a group of people standing about an old black ambulance wagon drawn by two mules that apparently could not proceed faster than a walk. Inquiry of the driver elicited the sad fact that a miner had bled to death.

In one of the Bethlehem steel mills, some years ago, there was started a first-aid and ambulance association.

The effort was attended with such success that the plan has now been extended to every mill and foundry of the company; and there is, today, not a department that cannot muster eight or ten men who are capable of attending an injured man properly.

Following an accident in one of the largest collieries in the anthracite field, I suggested to the foreman that a first-aid and ambulance association be organized for the purpose of instructing the men in giving necessary first aid in case of accident. I stated that men could be taught how to put a broken limb in an easy position, arrest bleeding from a severed artery, apply artificial respiration to those overcome by gas, or treat men rendered unconscious by electric shock.

Unwisdom of a Mine Foreman

Much to my surprise, however, the foreman argued that such a scheme, while a good one, would not be approved by the doctors and he refused to consider it further. Experience in later years has proved the fallacy of his contention; and doctors, today, take great interest in assisting to give the needed instructions in first-aid work to all mine workers. It must be remembered, of course, that the first thing to do, in case of a serious accident, is to send promptly for the doctor, while, at the same time, doing everything possible to prevent further injury and save life.

I recall an instance that occurred in the Wyoming Valley, some time ago, when 13 men were overcome by the afterdamp of an explosion, in a fruitless atempt to recover the bodies of two of their comrades who were killed by the force of the explosion. At such times many brave men are ready to risk their own lives in the hope of rescuing their less fortunate companions and restoring them to their families, who are on the brink of despair by reason of the accident. Here is where first aid to the uninjured would be valuable, in giving to these willing rescuers a knowledge of the danger incurred by going unprotected into places where an explosion has occurred.

Fred B. Hicks.

Kingston, Penn.

Favoritism in Mine Management

Letter No. 6—Speaking of the reasons that guide corporations in the choice of men to take charge of the several branches of their business, if every official who has the authority to choose his assistants was asked to give a reason for his choice, the replies received would be almost as varied as the men chosen.

One official will describe the man of his choice as "a young man who has the pep, push, vigor and vim to make things go." No doubt this is true as far as it goes. There are many men who can "make things go," but they do not always go right; and when things go wrong, someone will ask, "What are you going to do about it?" Let me say, the only thing to do, in that case, is to get a new man and try again.

A number of years ago I knew of a coal company who made it a rule to change their mine foremen at frequent intervals. The company operated a number of mines. At one mine, I remember that everything seemed to go wrong. The superintendent of the mine was a boy 20 years of age, who had been a timekeeper. The mine foreman was a young man of more than average attainments, but, like the superintendent, lacked the experience that one in his position should possess.

Both of these young men had plenty of push and go. Under their management, things moved, it is true, but the movement was not a steady march to success. Instead, things moved rapidly from bad to worse and, to save the situation that was fast becoming intolerable, the company decided on a change of mine foremen, which was then made nearly every month.

Inexperienced Management Bankrupts the Company

It is not strange to know that the result at this mine was a failure and the company went into bankruptcy. We are often led to ask why so many industrial concerns choose to employ young, untried and inexperienced men in an official capacity. Is it from a mistaken idea of economy? Can anyone think, for a moment, that the small amount saved in salary will compensate for the great loss that must result from the lack of experience on the part of the one given charge of the work? Efficiency and every vital consideration appear to be overshadowed by one idea, which the management are slow to realize is a false economy.

There are numerous instances about us where men are appointed to fill official positions more from the view point of *who* they are rather than *what* they are. A man may stand high in social and political influence and know little or nothing about coal mining; and yet, how frequently such a one is chosen for an important position by a large corporation, when the work he does most efficiently is to draw his salary. Like the wise old owl, they never talk because they could not instruct if they did. Someone must act for them at every turn.

Appointment of Favorites

In his letter, *Coal Age*, Apr. 6, p. 644, Richard Bowen says, "I do not think that any sane manager would place a man in a responsible position because he was a favorite in some respects." In this opinion, I cannot agree with Mr. Bowen. Whatever may appear as not reasonable, in this respect, the fact remains that such appointments are constantly being made by persons whose sanity has never been called in question.

Mr. Bowen, also, appears to have some curious ideas in respect to the practice in coal mines, in England. It seems strange to me where or from what source he could have obtained his information. In my opinion, he has been wofully deceived in respect to the conditions that he states exist in the mines of that country.

When we compare coal mining in this country with that in England, it would appear that we have done little more than to tag on behind. There is little that seems to me to be of original character in American mining, but we have thought out and accepted British ideas and made use of their experience in forming our mining laws, as well as in other matters relating to the operation of mines. In other words, we have been following in the footsteps of our English cousins. There is no doubt but that we have the men and the brains and should follow our own initiative.

Confluence, Penn. H. E. Gray.

INQUIRIES OF GENERAL INTEREST

Mine-Car Door

In the hope of obtaining some good suggestions from readers of *Coal Age*, allow me to present, for their consideration, a proposition that is causing us some study and thought. Our miners are loading only hand-picked lump coal, which is mined in large chunks and must be loaded into the mine cars where the seam is not more than 38 in. in height.

Up to the present time we have used cars without doors, but operating conditions make it necessary now to equip all cars with doors. The door must be such that it can be laid flat while the car is being loaded and quickly put in place by the miner before the car is finished. At the same time, the door must be adapted to the requirements of a self-dumping cage and must be in a position to clear when returning into the mine.

Russellville, Ark. V. C. ROBBINS.

We gladly submit this question to our readers and hope that they will be able to make some good suggestions.

Taking Anemometer Readings

When taking anemometer readings in an airway that is wider at the bottom than at the top, having the form of a trapezoid, how should the anemometer be held, in order to secure an average reading for the entire cross-section of the airway? I have in mind an airway that measures 8 ft. 4 in. on the bottom and 6 ft. 8 in. at the top, while the clear height of the passageway is 4 ft. 4 in. Will a reading taken in the center of this airway give the average velocity of the air passing?

——, W. Va. ASSISTANT FOREMAN.

The fact that this airway has the form of a trapezoid, and is wider at the bottom than at the top, does not materially affect the manner in which the anemometer readings should be taken, in order to secure an average reading for the airway. As has frequently been explained in *Coal Age*, the velocity of the air current is always greatest at or near the center of the airway, except where the conditons are such that the air has a tendency to hug one side of the airway, as in a sharp bend, or where certain conditions may cause the air to travel in larger quantity along the roof or the floor of the airway. These conditions have been fully explained in reply to the inquiry on "Measuring Air Velocity in Mines," May 4, p. 848.

In measuring the velocity of an air current in an airway having the shape of a trapezoid, we would suggest holding the anemometer an equal time, say a foot off the bottom and twice that distance below the roof, at points a foot or so to one side of the middle of the airway. Under ordinary conditions this may be expected to give a fair average reading in a 5- or 6-ft. airway.

As previously mentioned, however, it is of more importance that the same method be followed, each time, and that the readings be taken in the same place in the airway, in order to secure relative uniformity in the results. It must be remembered that velocity readings taken with the anemometer in an airway are only approximate, but the readings taken from time to time should be such as can be compared, for which purpose the method of taking the readings must be uniform.

Mixed Explosives in Blasting Coal

Kindly explain what is the danger in charging both powder and dynamite in the same hole when shooting slate roof in a mine. I have been doing this for several years with good succecss; but recently our mine foreman informed me that the district mine inspector gave orders that the practice must be stopped, as it was dangerous. PRACTICAL MINER.

Dubois, Penn.

The mine inspector is right. The habit of some miners of placing a small piece of dynamite in the foot of the hole, before inserting the powder cartridges is a dangerous practice. The purpose of the miner is to break the coal at the back of the shot, hoping thus to obtain a larger fall of coal than would be produced by a charge of powder alone. He claims that the quicker and stronger action of the dynamite, at the toe of the shot will serve to crack the coal at that point, and enable the charge of powder to break it down more readily and in larger quantity.

Attention has been drawn frequently, in *Coal Age*, to the fact that the explosion of the dynamite at the bottom of the hole is quite uncertain. It often happens that the explosion of the powder is not followed, as expected, by the explosion of the dynamite, which is found later in the coal thrown down by the shot. This is the chief source of the danger of using dynamite with a charge of powder. Dynamite should never be fired without a detonating cap.

It may chance that, owing to the quicker action of the dynamite charged with black powder, the explosion of the former may rupture the coal in such a manner as to cause a windy shot or "squealer." Or, the entire charge of black powder, or a large portion of it, may be thrown from the hole by the explosion of the dynamite and exploded in the air and cause disaster.

As stated in the inquiry, this practice of miners has been employed in numberless cases with good success; but it requires the best judgment on the part of the miner and, even then, there is no assurance that an accident will not happen. For this reason, the practice should be abandoned. The practice of mixing different grades of black powder in the same hole is also an exceedingly dangerous practice and should never be permitted.

EXAMINATION QUESTIONS

Illinois Mine Managers' Examination April 2, 1918

Ques.—When the air current in a mine contains marsh gas, which is the most dangerous, air saturated with water or unsaturated?

Ans.—When the air circulating in a mine generating gas is unsaturated it has a tendency to absorb the moisture from the roads and workings, which renders the mine dry and dusty and presents a more dangerous condition than would occur if the air current was maintained in a saturated condition.

Ques.—A seam of coal pitching at an angle of 16 deg. measures 6 ft., at right angles to the dip. What is the vertical thickness of the seam and the gross tons per acre, the specific gravity of the coal being 1.25? The cosine of 16 deg. equals 0.96126.

Ans.—The vertical thickness, in this case, is $6 \div 0.96126 = 6.24$ ft. The cubic contents of this seam, per acre, is then $43{,}560 \times 6.24 = 271{,}814+$ cu.ft. The specific gravity of the coal being 1.25, the weight of coal, in gross tons, underlying one acre is

$$\frac{271{,}814 \times 62.5 \times 1.25}{2240} = 9480 \text{ gross tons}$$

Ques.—When a person comes in contact with a bare electric wire carrying 275 volts, which do you consider the most dangerous, alternating or direct current? Give reasons why.

Ans.—The question does not state, what is of the most importance, the amperage of the current; and it is difficult to state which, if either, of these two kinds of electricity would prove the most dangerous, with only 275 volts. It should be remembered that, with this low voltage, it is amperage, or the volume of current flowing, that is the determining factor in respect to the effect produced on the human system.

An electric current may prove fatal to life in either one of two ways: (1) by shock to the nervous system; or (2) by the heating effect produced by the resistance of the body and which burns the flesh and dries out the blood. The first contact of the body with a live wire carrying *direct current* produces a shock in proportion to the voltage of the current. The shock is immediately followed by the heating effect, which depends on the quantity of electricity flowing through the body, or the amperage of the current. On the other hand, if the wire is carrying alternating current, there is a rapid repetition of the shock due to the voltage, and this rapid succession of shocks increases the danger and may prove fatal if continued, even though the amperage be small. Replying, then, to the question asked, bearing the foregoing facts in mind, it may be said that a direct current of considerable amperage, even with this low voltage, might be considered as more dangerous than an alternating current of the same strength and pressure, although many will agree that there is not much choice between them.

Ques.—If a collar or crossbar, 8 in. in diameter and 8 ft. between supports, bears a certain load what should be the diameter of a collar or crossbar, 12 ft. between supports, to bear the same load?

Ans.—In mining practice, it is the roof pressure or load per running foot of beam that determines the required strength or diameter of the beam; and the words "the same load" may be taken as referring to the same *unit load* resting on the collar. In that case, the cube of the diameter of the beam will vary as the square of its length or distance between supports. In other words, for the same unit load, the cube of the diameter ratio is equal to the square of the length ratio. Hence, calling the required diameter of the 12-ft. beam x, we have

$$\left(\frac{x}{8}\right)^3 = \left(\frac{12}{8}\right)^2 = 1.5^2 = 2.25$$

$$x = 8\sqrt[3]{2.25} = 10.48, \text{ say } 10\tfrac{1}{2} \text{ in.}$$

Ques.—State fully how powder and other explosives may be taken into a coal mine, and what precaution is necessary in handling powder and other explosives. State what is the maximum amount each miner is allowed, at any one time, and where same must be kept.

Ans.—The coal-mining laws of Illinois require that the powder must be taken in after the shotfirers have left the mine and before the entry of the dayshift for work. Explosives must not be carried in the same car with tools or other materials. The law provides that no workman shall have at any one time in the mine more than 35 lb. of black powder or more than 25 lb. of permissible explosives and not more than 3 lb. of other high explosives. All explosives must be kept in a wooden box, securely locked, which must be placed as far as practicable from the track and from other boxes in which powder is stored. Black powder and high explosives or caps must not be kept in the same box. Likewise, detonators must not be put in the same box with detonating explosives.

Ques.—In coal mines where heavy blasting is done, or in mines generating a large or small percentage of marsh gas and where fine dry coal dust has been allowed to accumulate on the roadways and timbers, sides or ribs, state fully what might take place if these conditions were allowed to exist. What mixture of marsh gas and coal dust will explode when ignited?

Ans.—Under the conditions named, a blownout shot caused by an overcharge of powder or a badly placed shot would be likely to cause a destructive mine explosion that would be propagated throughout the mine by the gas and dust accumulated on the roads and in the working places.

That coal dust lowers the explosive limit of firedamp is well known; but the percentage of gas and dust in the mixture cannot be stated, as this will vary with the inflammability of the coal, the amount and fineness of the dust and the character of the flame causing ignition.

COAL AND COKE NEWS

Harrisburg, Penn.

State Fuel Administrator William Potter has announced that he will turn over to the United States District Attorney evidence in the case against James Brothers, of Pottsville, Schuylkill County, accused of shipping to market four carloads of anthracite which contained from 14 to 47 per cent. slate. At a hearing held on May 22, Mr. Potter upheld an order of Baird Halberstadt, fuel administrator for Schuylkill County, who closed the company's colliery until June 1 and sent four cars of coal back to be unloaded and prepared for market.

The cars were en route to market and ordered back from St. Clair scales by Halberstadt. The state administration ruled that the cars should be hauled back to the colliery, unloaded, and before any coal can be loaded into the cars, the county administrator must certify that the cars were unloaded.

The state administrator also ruled that the Cambridge Colliery must be closed until June 1, and shall be allowed to operate after that date only provided changes have been made in the breaker and its machinery that will enable the operators to better prepare their coal. At resumption of operations, only coal that is freshly mined may be run through the breaker. Dumping of culm banks is prohibited. All shipments from the colliery will be inspected by representatives of the administration, and if found below standard, operations will again be suspended.

There was from 17 to 47 per cent. slate in the condemned cars. Some of the coal was consigned to the Home of Indigents. The gravity of this case has been aggravated by James Brothers, who on former occasions obtained permission to ship a car of condemned coal for use in a slate quarry owned by them. Instead of shipping the coal as they were given permission to, the operators sold the coal into the anthracite pool at Port Richmond, where it was mixed with high-quality anthracite.

Because of the repeated warnings given these operators, and the lack of defense on their part, it has been decided that the evidence in this case will be presented to the Federal District Attorney with recommendation for violation of the Lever act, and as a warning to other operators.

Charleston, W. Va.

The apportionment of cars to the several West Virginia coal fields, including the Kanawha & Michigan district, the Kanawha district and the New River district, appears to be most satisfactory. The car supply in the New River district, for instance, reached about 90 per cent. this week, and operators confidently look forward to a better supply next week because most of the shipments from here were for tidewater, so that there ought not to be any undue delay in the return of such cars.

The production during the week ending May 18 was 137,862 tons and the total of hours worked was 3344. Total hours lost because of car shortage was 639, and because of labor shortage 339. Just 24 hours were lost because of a strike, while on the score of mine disability (and in that is included power shortage) 277 hours were lost. All other causes were responsible for 104 hours of lost time. Between May 1 and May 23, a total of 27,322 loads were shipped out. In the same period the empties received amounted to 26,624.

In the New River district the situation, insofar as cars are concerned, is regarded as being much improved, although it is not so good this week as it was last week. While the problem which now confronts the operators is almost entirely a transportation problem, should there continue to be an improvement in the car supply so that mines would be able to produce to their capacity, the problem will be entirely a labor problem.

Coal operators believe that the amendment proposed by Provost Marshal General Crowder under which men in practically all occupations will have to work or fight is going to have a wholesome effect in the mining industry, where many miners are indifferent to whether they work full time or not. One suggestion which has been made is that concrete plans be adopted by all operators to check men in and out.

The car supply fell short of what it has been during the last month in the Fairmont district, the supply in the Fairmont field fluctuating between 700 and 900 cars.

Returning from the Villa mine of the Mill Creek Canal Coal Co., where 13 lives were lost as the result of an explosion of a gasoline engine which furnished power for a fan within the mine, W. J. Heatherman, Chief of the Department of Mines, after pointing out that the mine had not been inspected since April, 1917, issued a statement saying that he would close every mine in the state which did not remove any fans which were operated within the mine. In his statement the new mine chief said: "The records of this department show that this mine had not been examined since Apr. 25, 1917, and was classed in first-class condition, when the facts are that it was found to be in a deplorable condition. Not only the department of mines, but the owners and officials of the mine have shown the greatest disdain for human life and property, or they would not have allowed a gas-driven fan to remain over 400 ft. within the mine when it should have been installed on the outside. Since this occurrence this department has been advised that a great many mines throughout this district have fans inside the mines. This is to advise that any fan found within the mines in the future, whether gas-driven or otherwise, must be removed at once."

Birmingham, Ala.

In the Birmingham mining district conditions show little improvement. The local output is still under what many think it should be. Labor is being urged to greater activity and mine employees, both whites and negroes, at ore and coal mine, are being asked to give their best effort to steady production, as an increased output of ore and coal is needed to keep up the production in war industries and to meet the ordinary demands of the public.

The ore and coal miners are also being urged to give their work closer and better attention in an effort to produce the cleanest coal and ore possible, as carelessness in mining and dirty product has proved most costly to the Government thus far.

Coal production is scarcely above the steady demand, and while Federal fuel administrators are advising that some coal be stored for use in the fall and winter, so far little has been accomplished.

There is no complaint to be heard of the railroad car service in the mining district. The only dissatisfaction arising during the week has been because of unsteadiness and inefficiency of the labor.

Victoria, B. C.

The use of powdered coal to replace fuel oil is the subject of experiment in British Columbia. In Vancouver City the B. C. Sugar Refining Co., one of the largest of the Provincial industries, has installed a plant to provide for the change and, it is understood, is getting satisfactory results. The Canadian Collieries (Dunsmuir) Ltd., anticipating a demand for the new fuel, is making tests of waste from its washery which has been accumulating for years in the harbor at Ladysmith, B. C. If the results prove what is expected, the company will install special equipment for pulverizing and will proceed with the reclaiming of this coal refuse, of which there must be four or five million tons and some of which has been lying under water for 17 years. It is considered probable that, should the experiments now under way turn out right, and providing the United States withdraws the "tankers" at present in service between California and British Columbia, the Canadian Pacific Railway Co. will arrange for the use of coal dust in locomotives now burning oil.

An interesting sidelight on the increased value of coal in the Canadian Northwest is obtained from an experience of the Pacific Coast Coal Mines Co. In prewar days the company discharged its waste into a lagoon, across which a rough cofferdam had been constructed. George Wilkinson, then manager of the company's operations, and now Inspector of Mines for British Columbia, was responsible for this. His idea was that this coal, for which there then was no market, might prove useful in an emergency. Last year some 50,000 tons of it were recovered and sold at $3 a ton.

A new company, known as the Canadian Western Fuel Co., has been incorporated in British Columbia for the purpose of purchasing, taking over and operating all the assets in British Columbia of the old Western Fuel Co., of San Francisco, Cal. The incorporators of the new company are G. W. Bowen, J. B. Bowen and John Hunt, and the capital is $5,000,000. There will be no change in the management of the company as at present constituted, and its headquarters will be at Nanaimo, B. C. G. W. Bowen is the general manager and John Hunt remains the general superintendent. J. B. Bowen is the manager of the Western Mercantile Co., the trading establishment opened by the Western Fuel Co. when it was reorganized a year ago.

The Granby Consolidated Mining and Smelting Corporation, in the course of developing its newly acquired coal bearing areas near Nanaimo, B. C., has driven three slopes. On one, at a depth of 150 ft., a seam, 14 ft. at that point, has been opened up. The management express themselves as satisfied with the results up to date.

The purchase of the Vancouver Island properties of the Nanoose Collieries, Ltd., by the Nanoose Wellington Coal Co. has been announced. Lewis Williams, president of the purchasing company, has given a statement to the effect that it is the intention to push the development of the coal-bearing areas controlled by the new concern to the end that the present output may be trebled.

PENNSYLVANIA

Anthracite

Wilkes-Barre—Only $1 damages was awarded by a jury on May 25, in the suit of Mrs. Elizabeth Alexander against John Conlon, an independent operator of Plains township. Mrs. Alexander was unable to prove to the Court's satisfaction that damages to her property were caused by the Conlon operations.

Pottsville—The ruling of Provost General Crowder on the draft question may affect all strikes after July, declare labor leaders, who say that such a strike as is now being conducted at the Philadelphia & Reading Coal and Iron Co. shops may be banned by the order. These men, many of them of draft age, have been idle a week, demanding a 30 per cent. increase of wages.

Hazleton—Anthracite operators in the Lehigh field expect a record output for May. Thus far there has not been one day of idleness outside of Sunday, and the supply of cars has been better than at any time within the last two years. Despite the unfavorable attitude of workers, companies still hope the men will meet their request to continue at their places on Memorial Day.

The departure of 120 boys from here and 89 from Freeland, in the draft quota on May 27, has made such inroads on the operating forces of the coal companies that an appeal will be made to the district exemption board at Scranton at once to place all miners in deferred classification. It is contended that miners are as necessary at the collieries for the successful prosecution of the war as they may be at the front.

Bituminous

Stroudsburg—The Lackawanna R.R. is storing 2000 cars of bituminous coal at the Gravel Place, East Stroudsburg, for use in case of a coal shortage in the next year. The coal will be left there until needed by the company.

Uniontown—Coal land in Fayette County reached a record price recently, when the Jamison Coal and Coke Co. purchased 550 acres of coal land from the Alfred Fuller estate for $1,760,000, which is $3200 an

acre. The tract is the last of the large undeveloped coal tracts in the county and is situated near the holdings of the Washington Coal and Coke Co., extending to Perryopolis.

WEST VIRGINIA

Fairmont.—John Y. Hite, who has extensive operations in this section, has consummated negotiations for the purchase of 27 tracts of coal land in Harrison and Marion Counties from the Whyel Coal Co., of Uniontown, Penn., the consideration being $585,000.

Williamson—Coal is again being shipped from what is known as the old W. J. mine, near here, by Harry Randolph, who recently acquired the mine.

The tipple of the Bailey Coal Co. on Pond Creek, near here, destroyed in the February flood, just as it was being completed, has been rebuilt, and coal is again being shipped. The superintendent and general manager is Capt. E. L. Bailey.

New machinery is being installed and new houses being built by the Wilhelmina Mining Co., near here. The superintendent of the company is Jack Goodloe.

Junior—According to figures furnished by an officer of the Gage Coal and Coke Co., which operates near here, that company will expend $150,000 on improvements to be made to its plant. This company owns 640 acres of Kittaning coal and improvements will be begun immediately. It is proposed by the company to transport part of the output of the mines across the Tygarts Valley River to be converted into coke. The improvements to be made will consist largely of electrical equipment. The estimated capacity of new work in tons per year is 800, and the estimated capacity of plant when completed in tons per year is from 150,000 to 175,000.

Welch—The Standard Pocahontas Collieries Co., at Caples, McDowell County, has appropriated $20,000 for improvement in its mining facilities.

In round numbers $100,000 is being spent for improvements at the Ocean mine of the Marine Pocahontas Collieries Co., near Roderfield, the company only recently having completed a track to the mine.

A new bucket and cable system has supplanted the bridge formerly used by the New Pocahontas Colliery Co., at Hemphill, the bridge having been destroyed several months ago in a flood. A new stone storeroom and office is being built by the same company at its Deegan plant.

Jessop—Fire of unknown origin completely destroyed the power house of the Saxon Coal Co. last Saturday. Many tools belonging to employees were destroyed.

Roderfield—A modern plant is being constructed by the Hampton Roads Mining Co. at this place. The Hampton company is a subsidiary of the Pocahontas Collieries Co.

Charleston—Additional equipment is being installed by the Valco Coal Co., at Greenview, W. Va.

Preparations are being made by the Davis Creek Coal and Land Co. to sink a slope to the Coalburg seam. R. N. Snyder is general manager, with headquarters at Charleston.

Morgantown—The Monongahela R. R. has applied to the Government for permission to expend $225,000 in the construction of a railroad along Scott's Run, paralleling the Morgantown and Wheeling R. R., the company setting forth that the purpose in desiring to build up Scott's Run is to accommodate the Osage Coal Co. and the Cleveland and Morgantown Co. The Morgantown and Wheeling Railroad Co. has entered a protest against permission being granted for the Monongahela extension.

Bluefield—One of the largest deals that have been made in the transfer of coal properties in the Pocahontas field of south West Virginia was completed on May 15, when Frank S. Easley, of Bluefield, acting as trustee of parties of Bluefield, Lynchburg, Va., and Welch, W. Va., purchased through L. A. Osborn, mining and construction engineer of Welch, all the holdings of the Bradshaw Pocahontas Coal Co. Several tracts of land that the Bradshaw company was operating under lease were purchased in fee. The new company will have approximately 1500 acres of the Bradshaw Pocahontas seam of coal, which will average 60 in. clean coal. The present equipment will be immediately enlarged for a capacity of 1000 tons daily.

ALABAMA

Birmingham—The Woodward Iron Co. will begin at once the construction of a large Link-Belt concrete coal washery at its Woodward Furnace plant, which it is understood will cost in the neighborhood of $200,000. Construction work of every character in this district is being seriously retarded both by the shortage of skilled and unskilled labor and the inability to secure material and equipment without long delay.

It is announced that the Central Alabama Coal and Iron Co. will rehabilitate Jenifer furnace, located at Jenifer, in the western part of Jefferson County. Extensive improvements will be made in the machinery and equipment, including the installation of electrical power apparatus, the building of an ore washery and the addition of fifty coke ovens to the present battery of 100 ovens. Coal will be obtained from the company operation at Weller.

INDIANA

Petersburg—Every coal mine along the Evansville & Indianapolis R.R. has resumed operation after an idleness of eight weeks. The shutdown was caused by a dispute over freight rates which has been settled by the Federal Government. Reopening of the mines means an increase of about 25,000 tons of coal a week in Indiana. The various shafts employ about 1000 men. Cars are being supplied now by the railroad company in satisfactory allotment.

New mines are being opened by the Atlas Co., north of Petersburg. Seven machines will be used in taking out the coal and approximately 350 men will be employed in the work. The Petersburg Business Men's Association has been asked to build 50 houses to accommodate the increase in workmen. Hundreds of miners who left Petersburg and vicinity when the mines closed are returning.

Terre Haute—Vincenzio Boaso, president, and Lee Poll, secretary, of United Mine Workers Union of America, Local No. 6044, at Blanford, Ind., have reported that the union has adopted resolutions, in the form of a memorial, to be placed before the Indiana Supreme Court in the form of an appeal. The miners are requesting the right to be allowed to keep beer in their homes for family use, claiming that they do not care for saloons or whisky, but feel that they should be entitled to secure beer for home use and show that they are violently opposed to state-wide prohibition as now effective if it interferes with home consumption of beer.

OHIO

Oreton—Three thousand acres of coal, clay and oil land, located at Oreton, Vinton County, have been purchased by Chicago men. Two of the interested parties are L. D. Binyon and J. A. Hogan, well known in Columbus, and the present operators of the Union Furnace Brick Co., at Union Furnace, Ohio. Mr. Binyon and Mr. Hogan were in Columbus last week consummating the deal and arranging for the development of the property. Immediate steps will probably be taken to open coal mines, and later developments will undoubtedly include the production of firebrick, oil and gas.

San Toy—During the first half of May, Edward Blagg, at the No. 1 mine of the Buckeye Coal and Railway Co., loaded 258 tons of machine-mined entry coal in 12 working days. The entry is 15 ft. wide and the coal 3 ft. 8 in. high. On May 10 Blagg loaded 31 tons of coal in eight hours. His total credit for the two-weeks' pay was $188.57. The coal was cut by a Sullivan C. E. 7 shortwall machine and gathered by a Goodman, articulated-type storage-battery locomotive.

ILLINOIS

Nokomis—After a five days' fight with fire which broke out Saturday night, May 18, in the Peabody No. 2 North mine here, announcement was made by the mine officials on Thursday, May 23, that the flames were under control and that it would not be necessary as had been feared, to seal the mine. Damage estimated at $75,000 to $100,000 has been done, however, and it will be at least three months and probably six months before resumption at full capacity will be possible. Fire has been smoldering in the mine for seven years, behind concrete walls. Seepage is thought to have affected the sulphur deposits, causing the flames to burst through. The large machine shop and power plant below the surface were destroyed. More than a hundred men were employed at $1 an hour to fight the fire. On account of the gas and smoke they could only work 10 min. at a time, with rest intervals of 15 min. The method was to put streams of water into the mine with all the hose that could be obtained. The mine employes about 800 men. Its output is about 2000 tons a week.

KENTUCKY

Lexington—A big deal has been put over whereby the Elkhorn Coal Co. has increased its capital stock from $100,000 to $600,000, and absorbs the Detroit Elkhorn Coal Co., which has for some time owned and operated adjoining property. The stockholders of the two companies have taken up additional stock in the Elkhorn Coal Co., which in amending its charter broadened its scope considerably. The officers of the company are S. L. Bastin, of Lexington, president, and T. J. Cassidy, Lexington, secretary-treasurer. Most of the capital is held by Detroit and Lexington capitalists, several others being from the Hazard and Letcher County districts.

Providence—U. B. McGraw, a baker of Providence, finding that there was little money in the bakery business under strict Government regulation, is opening a coal mine in the White Oak district, on the Illinois Central R.R., about five miles from town. The coal is of the No. 9 variety.

Louisville—According to recent newspaper announcements from the Whitesburg, Ky., district, the Kentucky River Headquarters' Coal Co. is planning to develop several hundred acres of coal land along the headwaters of the Kentucky River in Letcher County. The property is alleged to have been purchased some time ago at a cost of about $100,000. Several Louisville people, including K. U. Meguire, are said to be interested in the development. Mr. Meguire is in North Carolina and the report could not be verified.

Paintsville—The business of the bankrupt Jennis Creek Coal Co. has been sold by Attorney H. S. Howard to a new organization composed of H. S. Howes, R. A. Patrick, James A. Williams and James W. Turner.

Foreign News

Sydney, N. S.—The construction of the 120 new Koppers byproduct coke ovens at the plant of the Dominion Iron and Steel Co., with complete apparatus to recover the gas, tar, ammonium sulphate and other byproducts, is nearing completion, and the early starting of the first 60 ovens is now hoped for. This installation represents the latest word in byproduct coke-oven design, and will produce more coke with a smaller labor supply.

Personals

J. W. Massing has been made superintendent of the Long Branch Coal Co., in operation at Long Branch, W. Va.

Ben English, who has been mine foreman for the Booth-Bowen Coal Co., Simmonds, W. Va., has resigned and will engage with the S. J. Patterson Pocahontas Co. in the same capacity.

J. H. Hillman, Jr., of Pittsburgh, Penn., president of the Hecla Coal and Coke Co., and a director of the United Coal Corporation, has been elected a director of the Peoples Saving Trust Co. of Pittsburgh.

John Crooks, of Hazleton, Penn., has been named manager of the Pardee Brothers coal-mining interests to succeed the late Calvin Pardee. Mr. Crooks had been employed as superintendent of the collieries.

Earl Henry, who was chief mine inspector for West Virginia for 16 years, has been appointed superintendent of the West Virginia Rail and River Coal Co., of Columbus, Ohio, with headquarters at Hallwood, W. Va. He succeeds **Joseph West**, who has taken a similar position with the Rive Mining Co., of Dayton.

E. W. Blower, of Columbus, Ohio, secretary of the Hisylvania Coal Co., the D. C. Thomas Coal Co., the Piney Fork Coal Co., and the Pan Handle Collieries Co., announces that he will join the colors within a short time. He will retain his title in the four companies. During his absence his work will be looked after by **John L. Jones**, who has been appointed auditor, and **Elmer E. Leared**, who has been named sales manager and purchasing agent.

Obituary

Col. W. H. Mabie, who founded the town of Mabie, about seven miles from Elkins, W. Va., about 20 years ago, and who has since that time been extensively engaged in the lumber and coal mining business, died recently while on a visit to his old home at Tideoute, Penn. He was 73 years old.

John Morgan Lewis, who for a number of years has been a resident of Jeanesville, Penn., died suddenly in that town on May 21, a victim of heart disease. The deceased was 65 years of age, and was a graduate of Lafayette college in 1875. Afterward he was employed as a mine foreman for the Pennsylvania Coal Co. at No. 10 colliery. Then he stood the examination for state mine inspector to fill a vacancy in the Hazleton district, holding the position for five years. Later he was mining engineer for Coxe Bros. & Co., and then was associated with a number of smaller mining operations as operator. He is survived by his widow and two children.

Industrial News

Molus, Ky.—The Harlan Block Coal Co. has filed notice of an increase in its capital from $35,000 to $50,000, to provide for expansion.

Hazard, Ky.—The Kentucky River Coal Mining Co. has filed notice of an increase in its capital from $100,000 to $150,000, to provide for expansion.

Artemus, Ky.—M. T. Lindsay, president of the W. L. Blue Gem Coal Co., following action of the Board of Directors on Apr. 29, has filed notice of dissolution of the corporation.

Birmingham, Ala.—The Alabama Fuel and Iron Co. has recently acquired about 1725 acres of coal lands in the Harlan district of Harlan County, Ky., and is planning for immediate development.

Pikeville, Ky.—The Kentucky Elkhorn Byproduct Coal Co. is a new company which is starting operations at Shelby. H. L. Cox, one of the most prominent business men in eastern Kentucky, is superintendent of the new company.

Harriman, Tenn.—The Big Bend Coal Co. is planning for the immediate installation of machinery for the development of 500 acres of coal lands, to have a daily capacity of about 150 tons. L. O. Scott is president; Arthur W. Evans is manager.

Dora, Ala.—The May & Phillips Coal Co., recently incorporated, has perfected organization, and is planning for the immediate development of about 40 acres of coal lands, to have a capacity of about one car daily. John D. Phillips is president.

Kingwood, W. Va.—The Hoffman Coal Mining Co., recently incorporated with a capital of $30,000, is planning for the immediate installation of the necessary machinery for the development of about 200 acres to have an output of 300 tons daily.

Louisville, Ky.—The Byrne & Speed Coal Co. and the Jellico Laurel Coal Agency have filed suit against the city of Louisville for approximately $2000, representing coal purchased in October and November last, and upon which payment has not been made.

Norton, Va.—The Mohawk Coal Mining Co., recently incorporated with a capital of $50,000, is planning for the immediate development of about 1000 acres of coal lands near Keokee, to have a capacity of about 150 tons daily. H. P. May, of Norton, is president.

Pikeville, Ky.—The Middle Ridge Coal Co. is a new corporation that is being organized with Millard Burke as president; A. J. Younce, vice president and G. H. Francisco, secretary-treasurer. The main office will be at Pikeville, with mines at Elkhorn City.

Jenifer, Ala.—The Central Alabama Coal and Iron Co. is planning for extensive additions and improvements at its plant, including the construction of 50 new coke ovens at its coal mine in addition to the present battery of 100, the erection of a new washer at the brown-ore mines, etc.

Scranton, Penn.—The Delaware, Lackawanna & Western Coal Co. has taken bids for the construction of a large new coal breaker, about 140 x 140 ft. steel and concrete, to be located in the Providence section of Scranton. The structure is estimated to cost in the neighborhood of $250,000.

Wilhurst, Ky.—The Wilhurst Coal Co., recently incorporated with a capital of $20,000, has perfected its organization plans, and will commence work at once on the development of about 217 acres of coal lands to have a capacity of about two cars per day. J. C. Hurst is president; Ray Williams is vice president.

Belleville, Ill.—E. A. Daley, secretary of the Belleville Fuel Administration, has announced that the price of coal here will be advanced July 1 from 14c. to 15c. a bushel. The announcement followed a conference with the team owners' organization in reference to a demand for an increase from 75c. to $1 in the hauling rate, which has been approved by State Fuel Administrator Williams, to go into effect at once. The team men were persuaded to wait until July 1.

Richlands, Va.—The Richlands Coal Corporation, which recently filed notice of an increase in its capital from $50,000 to $300,000 is planning for the immediate development of extensive coal tracts acquired in Tazewell County, on the Big Creek branch of the Norfolk & Western Ry. The company will commence work at once on the construction of a new railroad siding to the property, the coal to be loaded with a tipple from a tramway It is planned to have a capacity of about 600 tons daily.

Toledo, Ohio—Activity prevails in the lake trade at the port of Toledo. This is shown by the records of loadings at the docks of the railroads. During the week ending May 25 the Hocking Valley docks loaded 125,000 tons as compared with 117,000 tons the previous week. The total loaded since the opening of the season is 493,000 tons. During the same week the Toledo & Ohio Central docks loaded 68,000 tons as compared with 64,000 tons the previous week. The total handled since the opening of the season is 266,000 tons.

Topeka, Kan.—The Kansas Retail Coal Dealers' Association was organized at Topeka, May 15, when 145 retailers of the state attended the meeting called by the Topeka dealers' association. T. J. Monhan, of Topeka, was elected president; A. W. Rich, Emporia, secretary and treasurer. The executive committee, consisting of two coal dealers from each congressional district, will promulgate recommendations, including those to the Federal Fuel Administration. The zone system as it operates was criticized by many speakers at the convention.

Fairmont, W. Va.—The car supply was fair for the week ending May 25 and starts off fairly good this week. The regional car shortage was 7800 on May 14, but the fair supply last week has reduced that slightly. The railroads are in good shape locally, according to H. Wilson, superintendent Monongah division of the Baltimore & Ohio, who reports that all loads were cleaned up by the start of this week. The Shippensburg gateway is in fair shape. There is an insistent demand for coal from this district for the lakes, but the Fuel Administration is trying to send it east.

Columbus, Ohio—Columbus domestic consumers will require more than 600,000 tons of coal for the year ending Apr. 1, 1919, according to figures submitted to the State Fuel Administration by James G. Young, secretary of the Franklin County Fuel Committee. This requirement is in addition to deliveries already made. Following a survey of the entire county, Young figured that for the year beginning Apr. 1 the county will need for domestic consumption alone 757,500 tons of coal. Of that amount 695,000 tons were figured as the need of Columbus domestic consumers.

Amarillo, Tex.—The Retail Coal Dealers' Association of Texas met in annual convention here on May 21 and 22, with dealers from all parts of the state in attendance. Coöperation with the Federal Fuel Administration in its campaign to induce industries and individuals to lay in their winter supply of coal during the summer months, while business is slack and transportation facilities can be had, was discussed at length and hearty indorsement given to all efforts of the Government along this line. Reports of dealers indicated that in all parts of the state the individual coal users are laying in their winter supply, and that the situation in this regard is most encouraging.

Bluefield, W. Va.—With only two out of the total membership of the association absent, the Pocahontas Coal Operators Association held one of the most successful meetings in its history in this city last week. Numerous matters of importance to the association were discussed, but definite action on a number of questions was deferred until a later meeting. George Wolfe and others who have given some thought to the subject presented to the association their ideas as to how the miners might be induced to work during the full time available. Mr. Wolfe has evolved some theories which he has been testing with excellent results, it is said, at his Winding Gulf operations.

Columbus, Ohio—The completion of the double-tracking of the Hocking Valley Ry. from Columbus to Toledo will be pushed as rapidly as possible with the money supplied by Federal Director of Railroads McAdoo. This is the announcement of M. J. Caples, vice president of the Hocking Valley Ry., who returned from Washington last week. He said that of the $25,000,000 allotted the Chesapeake & Ohio system, the Hocking Valley will get $5,600,000, a large part of which will be used in the double-tracking project. The work has been going on for some time, but scarcity of labor and money have held it up. Speeding up will start at once. The Federal Government realizes the importance of the Hocking Valley Ry. in moving coal from Ohio, West Virginia and Kentucky to the lower lake ports for shipment to the Northwest.

St. Louis, Mo.—The hearing on the application of the St. Louis Chamber of Commerce to the Interstate Commerce Commission for the abolition of the bridge arbitrary of 20c. per ton on coal, is to be held Monday, June 3, at the Jefferson Hotel. Joseph W. Folk, General Counsel of the Chamber of Commerce, has resigned to enter the race for United States Senator, but will make the argument in the arbitrary case. City Counsellor Daues will file an intervening petition, to make the city a party to the petition. The East St. Louis Chamber of Commerce has adopted a resolution declaring its intention to ask for an increase of the arbitrary unless St. Louis abandons its effort to have it removed. East St. Louis at present enjoys an advantage of 20c. a ton in the coal freight rate, although it is a part of the St. Louis industrial district.

Charleston, W. Va.—What is regarded as one of the most successful meetings of the New River Coal Operators' Association was held here last week when about 30 members of the association were in attendance. The meeting was for the most part devoted to a review of conditions in the coal industry. No fixed policy was discussed or proposed by the various members. The association went on record as favoring the continuance of the West Virginia Association, but as believing and urging that the association ought to be conducted on a business basis and that it should devote its attention to only those things which affected the coal industry as an industry. All the officers of the association were present, C. C. Beury, president of the association, presiding. The other officers are S. A. Scott, vice president; Ernest Chilson, Thomas Nichol, H. M. Bertolet and G. H. Caperton, members of the executive committee.

New York, N. Y.—The Coal, Ice and Wood Division for the Borough of Manhattan of the American Red Cross Second War Fund received contributions of over $107,000 in the campaign just closed. Among the largest contributions were: Delaware, Lackawana & Western Coal Co., $35,000; Williams & Peters, $10,000; John Markle, $5000 in Liberty Bonds; Dickson & Eddy, $5000; Pennslyvania Coal Co., $7000; Peale, Peacock & Kerr, $2500; Pennsylvania Coal and Coke Co., $2000; Thorne, Neale & Co., $1500; Whitney & Kemmerer, $2000; Burns Bros. $2500. R. H. Williams, of Williams & Peters, was chairman of the committee, and M. F. Burns, chairman of the Coal Division. James A. Hill was chairman of the Wholesale Bituminous Committee; John A. Whitely, chairman of the Wholesale Anthracite Committee; George Eltz, chairman of the Retail Committee, and Thomas F. Farrell, treasurer.

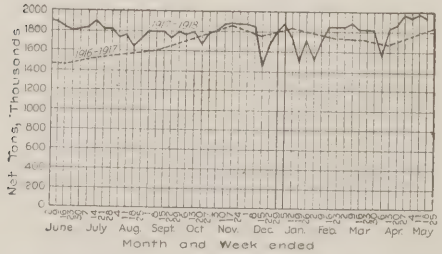
MARKET DEPARTMENT

Weekly Review

Output Still Below Requirements—Distribution Plan for Anthracite and Bituminous—Mine Price Reduced—Freight Rates Increased—Coal Denied to Less Essential Industries

RODUCTION of bituminous coal during the first five days of the week ending May 18 exceeded the 12,000,000-ton rate. On Saturday, however, output fell considerably, bringing the total for the week down to 11,732,000 tons, which is slightly below what was produced during the preceding week. The estimated weekly production of bituminous coal needed to cover our 1918 requirements is 11,900,000 short tons. Basing calculations on this estimate, the total actual production of bituminous to May 18 is more than 25,000,000 short tons behind schedule. For the first time in many weeks no car shortage was reported from the Pocahontas and Connellsville districts. In other sections operators received cars to only 50 per cent. of capacity, while the Fairmont region reported 71 mines idle owing to lack of cars. Though the car situation evidences signs of improvement, it appears likely that the shortage of labor in the mining districts will tend to keep output below maximum. Anthracite shipments for the week ending May 18 totaled 40,011 cars, the best showing since Apr. 6 and an increase of 2244 cars over forwardings for the week ending May 11.

A distribution plan for the entire output of both anthracite and bituminous coal has been decided upon by the Fuel Administration. The entire available supply will be apportioned by geographical districts and states so that every section will receive the entire amount that can be devoted to its industries. The production of bituminous coal will likely fall considerably short of the necessary quantity, and no material increase in the output of anthracite can be expected during the present coal year. The distribution plan was pushed to completion in order that every section of the country might be informed as to its exact status in relation to the available supply of coal and attempt to adjust its needs accordingly.



The reduction of 10c. per ton in the mine price of bituminous coal, and the order that all consumers are to pay the same price for their coal settled the long-standing controversy between the Fuel and Railroad Administrations. The net result will hardly show any effect in the gross tonnage; however, it will undoubtedly cause a more even output from individual mines. The increase in freight rates on both anthracite and bituminous coal will raise the cost to the ultimate consumer from 15 to 50c. a ton, but he will not grumble at that if he can only get all the coal he needs.

The Fuel Administration continues to deny soft coal to less essential industries which have not procured priority certificates. Preferred consignees, on the other hand, have learned that the filing of a statement of their last year's source of supply does not mean that the coal will immediately be shipped to them from the same mines. This is the case only when such requisitions do not conflict with special uses for certain grades. Byproduct industries, bunkering needs, plants where low sulphur coals are essential, and even domestic requirements, it is understood, will be given preferential consideration.

On the eve of "Coal Week" anthracite demand for all sizes continues to pour in. Dealers cannot fill orders of all customers even up to two-thirds of their requirements. Steam business is active, with buying for current needs and storage purposes going on actively. Railroads are now taking a large tonnage.

COAL PRODUCTION

The slump in loading on Saturday, after a good five-day performance, caused production during the week ended May 18 to decline slightly. The total production of soft coal (including lignite and coal made into coke) during the week of the 18th is estimated at 11,732,000 net tons, an average daily production of 1,955,000 net tons, compared with 1,971,000 net tons during the week of May 11. Beehive coke production

during the week ended May 18 is estimated at 678,000 net tons, an increase over the preceding week of 10,000 net tons or 1.5 per cent. The average production per working day amounted to 113,000 net tons, compared with 111,000 during the week of May 11.

Beehive Coke—Production of beehive coke in the Connellsville and adjacent regions declined slightly during the week ended May 18. The principal operators located in the Connellsville, Greensburg and Latrobe districts reported production of 318,605 net tons, or 69.2 per cent. of their maximum capacity, compared with 70.7 per cent. during the preceding week. The operators reporting had a hundred per cent. car supply during the past week and losses attributed to yard labor shortage declined from 19.4 per cent. during the week of May 11 to 14.4 per cent. Losses in potential capacity due to causes not reported, however, increased from 2.8 per cent. to 16.4 per cent. The same operators mined 129,950 net tons of coal.

Byproduct Coke—During the past ten weeks operating conditions in the byproduct industry have exhibited very little change. The ratio of production to maximum capacity rose from 87.5 per cent. in March to 89.6 per cent. on May 4, the maximum performance since the weekly statistics on byproduct coke were begun. Since that date the ratio declined to 89.2 per cent. the week ended May 11 and rose to 89.3 per cent. during the week of the 18th. Out of total losses of capacity of 10.7 per cent. during the week of May 18, 2.7 per cent. was due to lack of coal, 2.0 per cent. to labor trouble, 4.8 per cent. to repairs to plant, 0.3 per cent. to "no market" and 0.9 per cent. to all other causes. Material improvement, made possible by repaired plants, was reported by operators of New York State, the ratio of production to maximum capacity rising from 88.3 per cent. during the week ended May 11 to 93.7 per cent. Less favorable conditions, however, were reported by the operators of Alabama and West Virginia. In the former state the producing ratio declined from 91.1 per cent. to 88.3 per cent. and in latter state from 97 per cent. to 92.8 per cent., the decline in both states being due to repairs to plants. Minnesota alone continues to report loss of capacity due to "no market."

CARLOADS OF COAL AND COKE ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended Apr. 27	May 4	May 11	May 18
Bituminous shipments, 123 roads.	204,527	202,558	207,145*	205,026†
Anthracite shipments, 9 roads...	39,522	40,570	38,767*	41,011†

* Revised from last report. †Subject to revision.

Anthracite shipments were reported as 41,011 cars during the week of the 18th, an increase of the week previous of 2244 cars, or 6 per cent.

BUSINESS OPINIONS

Dry Goods Economist—The restrictions in imports recently put into effect by the Federal Government have further increased the shortage of merchandise. This condition is accentuated by the continued demands on domestic output for Government and Red Cross purposes, as a result of the expansion of our forces and their necessary adjuncts. An important development of the week was the sale of 5391 bales of German-owned cotton by the Federal Alien Property Custodian. More than 100 agents for cotton mills attended the auction and prices averaged close to 28c. a pound, while about 300 bales sold for 29¼c. These prices, being considerably above the Exchange quotations, indicate that the cotton offered was above the Middling Uplands grade.

American Wool and Cotton Reporter—The uncertainties which have been noted in

the woolen goods market are still present, and while some believe that certain of the difficult problems will be settled in the comparatively near future, there are many who feel that they will not be settled at all, except over a period of time, and that no definite arrangement will be made for any of the unsatisfactory features now existing. It is becoming more apparent as each week passes that the amount of goods which will be available from any section of the producing industry will be relatively small for some time to come. Few feel that there will be any great shortage of raw material, but that the inability to operate all the machinery available, and other similar conditions, taken in combination with the large Government requirements, will practically eliminate the production of any large amount of civilian merchandise.

Bradstreet's—Tightening of conditions in nonessential lines, further speeding up of war work, excellent crop news, and reports that large distributors are selling all the goods they can get after Governmental requirements are satisfied, comprise the mainsprings of the week's events. Because of a paucity of supplies at a time when shelves are being cleaned out of medium-priced goods, as the result of heavy buying flowing from abnormally high wages, linked, too, with concern about the likelihood of being unable to cover future requirements, final purveyors are buying liberally and as often as opportunity offers.

Atlantic Seaboard

BOSTON

Tension relieved somewhat by settlement of railroad fuel question. Policy of district representatives becoming better understood. Car service varies in different regions. Central Pennsylvania output near maximum on present car and labor supply. Only "preferred requirements" got shipments the past week. Many dess essentials fail to grasp the situation. Hampton Roads dispatch excellent, but the great urgency is still for ships. Three large colliers now definitely assigned for railroad fuel. Coal for inland distribution not yet limited to preferred consumers. No "free" coal. Anthracite receipts improve on April figures, but still inadequate. Steam sizes in good request.

Bituminous—There has been so little favorable news of late that the President's action on the railroad fuel mix-up was received almost with acclaim, such hopes have been built upon an equitable distribution of cars. Undeniably the trade feels a slight easing up on the subject of contracts, particularly with operations in Pennsylvania, but it is hard to see how actual shipments can be materially increased in the aggregate. Whole groups of mines there are, especially where freight differentials have tended in normal times to discourage commercial buyers, that have had absolutely no cars for several weeks except for railroad fuel, and it is fair to suppose now that commercial business will now be undertaken, at least to a limited extent. A lot of such coal came forward a year ago on high prices and was readily absorbed by requirements that are now on the preferred list; but on the other hand the railroads will now be obliged to take fuel from operations that recently have furnished none. The net result will show hardly any effect on gross tonnage; it will probably mean only a more even output from individual mines.

The 10c. horizontal reduction causes no comment whatever, it being viewed as a solace to the railroads. Buyers here are not at all interested in price; they are ready to buy coal in any direction by rail or water. Operators can be thankful that their net margins are so little disturbed, for had the railroad interests prevailed there might well have been such a reduction on output as a whole as might seriously have diminished production.

The Fuel Administration continues ruthless in denying coal to "less essentials." Shipments by the train-load have been diverted from paper manufacturers, for instance, who are engaged exclusively on goods for the Government; but apparently there is no redress unless and until the consignees are definitely granted priority certificates. There begins to be an attitude of resignation toward these wholesale reconsignments, although now and then there is a cry, "How long?" So far there is no sign of any change in the instructions of May 15.

Taking last week as a whole, car-supply showed a slight improvement, but different districts showed such variation a general statement is apt to be misleading. The territory tributary to the Baltimore & Ohio and the Western Maryland continues to suffer most, in some sections the shortage being in excess of 50 per cent. Open-top equipment is now withheld from all-rail service to New England on account of congestion due to shortage of locomotives. Box-cars with coal are allowed to come through, but the tonnage is necessarily so light that large industries looking to these districts for supply are beginning to despair. Similarly, the gas companies who depend upon the Pittsburgh region are much alarmed over the outlook there. Large consumers are being told their shipments are likely to diminish rapidly, since traffic conditions are so favorable to movement west. In the Fairmont district 71 mines were recently idle for lack of cars. The effect upon labor is serious.

In central Pennsylvania car-supply is not so far in arrears, taking into account the shortage of labor. The best opinion is that with the number of mine workers available and at what is now their average working time the whole district would be put to it to load 200 or 300 cars more a week, if they could be furnished. The average weekly output is a round million tons.

The smokeless regions in West Virginia continue to show the effect of "zoning" and the volume to the piers is fairly heavy. For what ships report the dispatch is excellent, steamers seldom being detained beyond the time necessary. The joint pooling arrangement is of great assistance, but the need of ships to speed up deliveries to this territory is still most urgent. A few of the lake-built steamers have now discharged their cargoes of Cape Breton coal and are arriving at Norfolk to begin regular service. Now and then a new ship like the "Tuckahoe" makes its appearance, but the number of bottoms is entirely too small to make up the arrears that stare us in the face. From Hampton Roads New England shipments since April 1, up to and including May 26, were 1,451,920 tons. When it is figured that 1,500,000 tons per month were estimated as necessary from Hampton Roads from April to October to give New England any reserve for cold weather he who runs may read what is in store for us.

Three steam colliers, the "Hampden," the "Transportation" and the "Coastwise" are now definitely in the coastwise service to carry fuel for New England railroads. Under favorable conditions these ships would together bring 800,000 tons a year, practically all of it from Baltimore piers.

Thus far there has been no effort on the part of fuel authorities to restrict the distribution of water-borne coal to preferred consumers either inland or directly on tidewater. It seems only a matter of days, however, when distribution will again have to be rigidly supervised, now that large numbers of consumers are cut off from service all-rail.

Persistent inquiry from buyers still outside the breastworks fails to disclose any "free" coal. While existing "contracts" can hardly be considered binding, yet those factors who consider themselves morally committed and have regard for their reputation are increasingly shy of additional business. That will be their attitude at least until more transportation is in view. The tremendous demand for over-sea bottoms now that our troops are crossing in such numbers is an element in the situation that must be taken into account.

All-rail movement remains on about the same level that has prevailed since Apr. 1. The average for May up to and including the 24th was 479 cars of bituminous passing the five gateways. At this rate the 1917 figures will be materially cut. To maintain 10,000,000 tons per year the average would have to be 617 cars daily. It will be interesting to see the result in June in view of the decision on railroad fuel.

The railroads take different views with regard to paying purchasing agents commissions. There have been recent instances both ways, the desire to keep a safe margin, however, being a consideration in some cases where the commission was paid. One of the larger roads is making frequent drafts upon commercial coal arriving for distribution and another is picking up from limited storage, the usual practice being to take current supply directly from cars. Stocks therefore are materially less than a fortnight ago.

It has lately been announced that questions of railroad fuel will not be handled by state administrators, but should be taken up direct with Washington where a new office has been established for the purpose. New England engine supply is so mercurial it will be interesting to see how this plan works. It probably means more "emergencies," and therefore greater interference with well considered plans of distribution by representatives of the fuel administration on the ground.

Anthracite—At a recent conference in Philadelphia between fuel administrators of the New England states and members of the Anthracite Committee it was "agreed" that 1,250,000 net tons per month domestic sizes would be furnished this territory. During April the receipts are computed to have been 950,000 net tons and while May is going to show an increase the total will be nine hundred thousand tons below the mark set. Rail movement shows a falling off recently, but water shipments are holding up fairly well. The companies are adhering closely to the 1916 distribution thus far, although the program is sure to work hardship to a number of communities where through war industries the population has increased by leaps and bounds.

NEW YORK

Anthracite receipts far below requirements, with dumpings reduced. Coal men watch efforts made to stock New England. Buckwheat coals in good demand with supply quickly absorbed. The bituminous situation active because of price reduction, settlement of railroad controversy and advance in freight rates. Dumpings for week show decrease.

Anthracite—Receipts continue to be far below requirements, as is evidenced by the reports of the number of cars dumped at the various local piers during the week ended May 27. These were 6205 cars as compared with 6346 cars in the previous week. Reports for the week ended May 18 show that 41,011 cars were shipped to market as compared with 38,767 cars the week ended May 11, an increase of 2244 cars, or 6 per cent.

Conditions are not favorable, and many complaints are heard of slow shipments. Few dealers can boast of much tonnage in their yards, while most of them lay claim to having at least enough orders on their books to keep their help busy for the next six months.

The order of the Anthracite Committee of the Fuel Administration of May 24 following a conference with the New England Fuel Administration that for the month of June a domestic tonnage amounting to one-twelfth of the shipments into New England during the coal year beginning Apr. 1, 1916, plus 50 per cent., shall be sent forward, caused some uneasiness here, the fear being expressed in some circles that this market is being slighted. It also resulted in new efforts being made to urge the appointment of a successor to Albert H. Wiggin, who resigned as State Fuel Administrator, several weeks ago.

Cyrus C. Miller, administrator of Bronx County, has notified Dr. Garfield that 1,451,250 tons of coal will be needed in that county during the coal year beginning Apr. 1, 1918.

The order of the Railroad Administration ordering increases in freight rates results in an advance of 30c. per net ton ton of 2000 lb. on coal; brought to this market. The trade was surprised at the largeness of the advance granted in view of the recent increase of 15c per ton. The advance does not become effective until June 25.

The local situation is far from satisfactory. Consumers are anxious about their winter fuel and the dealers are powerless to help them. The larger sizes, egg, stove and chestnut, are in good demand, with pea a trifle easier.

The buckwheat sizes are in good demand. The larger of these coals is moving freely, buyers being numerous and anxious to pick up free tonnages. The better grades of rice and barley are hard to find, while most consumers are just as anxious to pick up the cheaper grades.

Bids opened last week by the Department of Docks and Ferries for 71,100 gross tons, two-thirds buckwheat No. 2 and one-third semi-bituminous, resulted in prices of $7.39 and $7.59 per ton, the latter price being made where it was provided there should be a reserve stock of several thousand tons on hand at all times.

Another city department had the following prices submitted in a bid: 6000 tons buckwheat No. 1, $7.66 per ton; 12,000 tons buckwheat No. 2, $7.10; 500 tons pea coal, $8.06; 500 tons egg coal, $9.44; 1500 tons broken, $9.60; 4000 tons semi-bituminous, $7.80; 250 tons nut, $9.44, and 250 tons of stove, $9.44.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual
Broken	$6.55	$7.30
Egg	6.05	6.80
Stove	6.30	7.05
Chestnut	6.40	7.15
Pea	4.90	5.65
Buck	4.45@5.15	4.80@5.50
Rice	3.90@4.10	3.80@4.50
Barley	3.40@3.65	3.00@4.00
Boiler	3.65@3.90	

The Labor League of New York City, at a meeting held in the City Hall on May 24, adopted resolutions "that we emphatically insist upon the coal dealers of this city being compelled to secure and store coal to meet the requirements of the people of this city next winter."

The resolution stated that the local dealers are apparently not doing everything necessary that could be done to prevent a recurrence of the conditions existing in this city last winter, and that "it is practicable and possible for the mines to be operated and arrangements made with the Government to transport coal during the summer months."

The resolutions also recommend that the dealers ascertain the actual amount of coal needed to fill the requirements of all the people of the city "in a long and cold winter similar to the extraordinary conditions which prevailed last year and in previous years," that the Mayor's Committee should then ascertain if the coal dealers have sufficient storage facilities for keeping the coal on hand, and if the dealers are willing and ready to secure the coal now and have it ready for delivery to their customers during the winter months. The resolutions also provide that after storage places are secured the matter of securing the coal be immediately taken up with the Federal authorities, so that the mines will be furnished with a sufficient number of cars for the carrying of coal to this city, and that "in the event that the mine owners are not willing to mine the coal and the coal dealers are not willing to store it, we demand that the city through the Mayor's Committee, purchase the coal and have it on hand for every emergency."

Bituminous—There was considerable activity in the situation last week although receipts were far below requirements. The reduction of 10c. per ton from the mine price, and the order by which all consumers shall pay the same for their coal, settled the long standing controversy between the Fuel and Railroad Administrations and eases the minds of many operators who have been waiting for some such ruling for many weeks. While the order results in a lower price for the producer, he is apparently satisfied because there is going to be an equitable distribution of cars which means steadier work and a larger output. On the other hand, some operators say that with labor short they will have difficulty in loading many more cars than formerly.

The increase in freight rates to become effective June 25 means an advance of 40c. per ton on New York tidewater shipments. Consumers are expected to take kindly to the new price they will have to pay for fuel.

Dumpings at the local docks for the week ended May 27 were 6295 cars as compared with 6625 cars the previous week, a decrease of 330 cars, while the shipments for the week ended May 18 were reported as 205,026 tons compared with 207,145 tons during the previous week, a decrease of 2119 tons.

The Tidewater Coal Exchange has eliminated five pools at this port, assigning Pool No. 15 to Pool No. 14; No. 22 to No. 9; No. 23 to No. 11; No. 24 to No. 18 and No. 47 to No. 18.

Stocks are low and free coals continue scarce. Bunker coals are in good demand.

PHILADELPHIA

Anthracite deliveries unimproved. Shippers can give no promises. New England being favored. Estimated needs far in excess of production. Non-dealer shipments increase. "Coal Week" idea ridiculed by dealers. City bureaus urged to buy at once. Buckwheat exemption order being obeyed now. Bituminous situation displays slight improvement. Car supply better. Some concerns stocking fair tonnage. Price reduction will not surprise. Some contracting, with new forms in use.

Anthracite—Shipments into this territory are not increasing, and as the season advances the dealers and their trade are becoming more anxious. The bulk of the coal that is being received is consigned to the regular buyers, who have always depended on the larger shippers for their supplies. During the season of 1916-17, which is now being used as a basis for all shipments, there were thousands of tons shipped to other than the old line of buyers. Each dealer who had a car shipped during that period seems to be able to trace it to its source and is claiming at least the same tonnage now, but those who bought spasmodically or in small lots have thus far received scant attention. Some shippers claim that it is this class that is becoming most insistent for coal. It is not that any shipper declines to fill such orders, but they take the stand that they do not have the coal now and will endeavor to cover this tonnage later in the season.

Much disappointment has been expressed by the local dealers, who had expected an excess of tonnage for May over their alloted proportion. They had laid great hopes on this eventuality, owing to the fact that several of the larger companies had shipped them quite liberally in April. During the last week of the month just past any number of local retailers failed to receive a shipment from the big companies. They were candidly advised that they had received their proportion for May and were not at all likely to receive any more coal during the month. As a consequence many of them had their equipment idle.

Recently retail shippers have been inclined to criticize the rapidly growing practice of fuel committees in outlying sections in granting permission to various individuals to receive carload shipments. It will be remembered that the national administration had decreed the elimination of this practice except with the approval of local authorities in each instance. Recently the committees have taken the stand that such shipments are permissible where the buyers had made similar purchases in 1916, but are compelling the shipments to be made in care of retail dealers, who thereby get the hauling. However, the claim has been made recently that even this restriction has not been deemed necessary, and that persons with some influence have been able to obtain shipments without the necessity of having the coal sent in care of a dealer.

The wisdom of designating the week of June 3 as "Coal Week," when the public is expected to file orders for the coming fall and winter, is being severely criticized or referred to as a joke by the retailers here. Certainly this part of the trade needs no artificial stimulation. There are many who have far oversold their quota, and certainly none who with slight effort could not do so.

This week the state and local fuel administrators urged the city officials to endeavor to purchase early a large proportion of the coal needed by the municipal institutions for next winter. Messrs. Potter and Lewis, chairmen of their respective committees, have asked the city's director of supplies to lessen the red tape surrounding contracts let by the city, in order to expedite deliveries of coal. At the same time the city authorities were urged to make payment for fuel promptly, as often payments are considerably in arrears. While in usual times shippers were inclined to overlook this condition, yet at this time there is a decided disinclination to ship to any one where payment is not forthcoming within a reasonable period.

As to the relative sizes among the dealers there still continues to be no favored size. The situation is simply one of eagerness to get coal of any size, and no yard in the city has a stock of any kind of coal on hand. The consuming public undoubtedly has a preference as to size, but there is no difficulty whatever in having the customer change the size on request from the dealer to conform to such shipments as he may have at the moment.

The latest evelopment in the steam trade is the fact that the larger companies are now asking their customers using buckwheat coal to secure exemptions from Washington in accordance with the instructions issued by the anthracite distribution committee almost a month since.

The prices per gross ton f. o. b., cars for line shipments and f. o. b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.05	Buckwheat	$3.15	$3.75
Egg	4.50	5.70	Rice	2.65	3.65
Stove	4.75	6.05	Boiler	2.45	3.55
Nut	4.85	6.10	Barley	2.15	2.40
Pea	3.45	4.35			

Bituminous—It continues to look as if there is a continued improvement in the car supply, with a consequent increase of tonnage shipped to the city recently. Aside from the utility plants we are now able to notice other industrial enterprises which are beginning to accumulate some stocks of fuel in excess of current consumption. This is far from a general condition, but the signs are at least encouraging. Operators state that the labor supply is far from satisfactory, and signs of unrest among the men cause many anxious moments to the shippers.

Recently some shippers have closed contract business with big consumers, especially with trade they have not heretofore served very heavily, but who are among the most necessary and vital consumers. The idea appears to be that this business must be taken care of in any event. Most shippers have now received the approval of the new contract forms, the principal change being an insertion of the Garfield order of Dec. 24, 1917, bearing on the contract business.

BALTIMORE

Diversions of coal continue to make the bituminous situation here fairly easy, except on Pennsylvania line points. Hard coal men see big shortage ahead, and consumers are getting uneasy.

Bituminous—Through diversions of coal at junction points to the west of here, fuel for the most part originally destined for the Storrow account in New England, this section continues to receive a fair supply of bituminous coal. As the coal arriving here on direct consignment is confined practically to the preferential delivery list and for Government account, such as shipping, a serious state of affairs would exist for the less essential industries were it not for the diversions named. The various Government committees at Cumberland and nearby points are working hard to prevent any freight jams at the junctions, and whenever there is any evidence of congestion blocking progress on the northern connections the coal is at once rerouted through to this section and to the Washington district before it reaches the Cumberland scales. This method has kept the Baltimore & Ohio and Western Maryland lines pretty well open on direct shipment, and meanwhile the shipments have benefited consumers here. There is still complaint, however, from those consumers on the Pennsylvania who were cut off under the zone plan and who for the most part have found it impossible to make any new supply connections on the Baltimore & Ohio and Western Maryland lines. The Fuel Administrator and his committee here have been called upon repeatedly and have managed to keep these concerns going for the most part, although there was one shutdown reported the past week.

Anthracite—The more the hard coal men here delve into the prospects for the coming fall and winter the more convinced they are that a big shortage will be faced here. The trade is now engaged in compiling figures to show the amount of tonnage distributed so far, the amount of coal in yards, the immense increase in ordered tonnage, etc. These are to be carried to Washington by the local fuel administrator to prove that unless there is a decided increase in deliveries here the trade will not only fail to deliver the two-thirds on orders before fall, but the winter will be faced by many without sufficient supplies to carry through. The trade here has joined in with the general request of coal men that the administration in Washington stop urging people to insist on immediate deliveries of coal that is not here to distribute. The trade does not object to placing orders on the books, but the consumers are not satisfied, in the face of Government urging, to await deliveries, and many warm arguments are taking place. The National Fuel Administration urging has undoubtedly placed the retail hard coal trade in an unfortunate position.

Lake Markets

PITTSBURGH

Operators not enthusiastic about 10c. reduction. Car supplies better. A fair amount of stocking by consumers.

Pittsburgh coal operators have not enthusiastically approved the reduction of 10c. a ton in bituminous coal prices which went into effect at the beginning of this week, not only as to new sales but also as to deliveries, no matter when the contract was made. A few operators assert that they have been making practically no money. At the same time it is generally recognized that the 10c. reduction represents a compromise, the Fuel Administration having proposed a 20c. reduction to equalize with the fact that the railroads are to pay the full set prices instead of the much lower prices proposed by the Railroad Administration.

The wording of the official statement, that there will be no further changes in coal prices until costs for the 12 months ending Aug. 31 have been studied, suggests that the Fuel Administration has no thought of making any advances in future but has hopes of finding a basis for reducing prices further. All the operators, of course, are making much better cost showings than in the winter.

Car supplies in the Pittsburgh district have undergone some further improvement and are now fairly satisfactory. There is some shortage of labor, this being more noticeable than when operations were so much curtailed by car shortage, and fears are entertained that men will not be so eager to work now that there is less idleness enforced by lack of cars. Operators feel

that the men should work longer hours per week than those prescribed in the scale as minimum.

More coal is being stocked by the large consumers than formerly, and all show a willingness to stock to the limit of their ability, a willingness that will now be enhanced by the 10c. reduction in price. The majority of observers, however, believe that the rate of stocking thus far has not become high enough to insure that consumers will be carried through next winter without difficulty.

A moderate amount of coal is being sold in the open market, and the proportion that passes through brokers, with an extra brokerage charge to consumers, is somewhat reduced. Many brokers, however, are having a fair turnover from week to week. With the 10c. reduction, effective at the beginning of this week, the set prices are as follows: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, subject to 15c. brokerage in addition in the case of sales made by brokers.

TORONTO

Supplies of anthracite coming forward freely. Dealers filling winter orders. Bituminous scarce. Fuel Administrator advises dealers to order all they can. Wood as substitute fuel.

Supplies of anthracite are coming forward freely and the dealers are now filling winter orders, but owing to consumers having placed these earlier in the season than usual, there are large arrears to be overtaken. Shipments by water have so far been considerably smaller than during previous seasons. There is a marked shortage in the supply of bituminous, which is much in requisition. R. C. Harris, Fuel Administrator for Ontario, is advising dealers to place orders for all the coal they can, and expresses the opinion that owing to war conditions the supply will fall far short of meeting the requirements of consumers. He urges the municipalities to arrange for wood supplies in sufficient quantity to make good any deficiency.

Quotations for best grades per short ton are as follows: Retail anthracite egg, stove, nut and grate, $10; pea, $9; bituminous steam, $8.50; slack, $7.50; domestic lump, $10; cannel $13. Wholesale f. o. b. cars at destination, three-quarter lump, unprepared, $6.11; prepared, $6.31; slack, $5.18.

BUFFALO

Would be plenty of coal but for car shortage. Jobbers find it hard to keep going. Anthracite moving steadily by Lake. Local supply light.

Bituminous—The change in the situation is mostly due to lack of cars. Nobody seems to have a supply, and some of the mines get none at all some days. An increased amount of bituminous is moved in box-cars and yet the shortage grows. If the scarcity gets much worse it will be impossible to meet the most ordinary demands. At the same time the anthracite movement is at least normal, but that trade is allowed to use box-cars freely. Some of the lake shipping docks here now have box-car unloaders, so that they can move coal as well that way as by dumping.

The new order reducing the prices of bituminous 10c. a ton is not well understood here yet. It will reduce the following quotations by that much, if regularly effective: Allegheny Valley thin-vein, $4.45; Pittsburgh lump, $4.25; Pittsburgh mine-run, $4; Pittsburgh slack, $3.75, all per net ton, f. o. b., Buffalo.

Anthracite—The movement is fairly large. An average amount by lake is now going out and it does not appear to affect the local supply seriously, which means that the leading companies have diverted the usual amount from the eastern trade and that the upper lakes will get their regular supply. The city consumers are not making such feverish demands for coal as they were before the early warm weather set in, and it may be that they will soon find that they are getting enough to warrant the expectation of a full supply in good time.

Canada does not appear likely to slacken her demand for coal. In spite of the big supply of bituminous there and the advice to lay in some of that for emergencies, the retailers and consumers still beset the shipping offices here about as they did during winter.

Shipments of anthracite by lake for the week were 104,300 tons, of which 41,300 tons cleared for Chicago, 34,400 tons for Duluth and Superior, 10,800 tons for Sheboygan, 7500 tons for Green Bay, 4500 tons for Milwaukee, 3300 tons for Marquette and 2500 tons for Hubbell. Freight rates are 60 and 65c. to Chicago, 50c. to Sheboygan and Green Bay, 48c. to Duluth and Marquette, 55c. to Milwaukee and 45c. to Hubbell.

DETROIT

Diminishing receipts of bituminous and anthracite cause anxiety. Margin to retailers yet unchanged. Lake shipments not heavy.

Bituminous—Jobbers find that while there is a comparatively free movement of bituminous coal into Detroit, the shipments are largely of mine-run, and that other sizes are coming in in small amount. Users of steam coal with plants adapted to consumption of mine-run are having little difficulty in providing for their requirements. Those who are accustomed to use slack, nut or pea sizes find it less easy to obtain the coal they desire. The demand from consumers of steam coal continues steady and is well maintained.

There is a noticeable deficiency, jobbers say, in the supply of domestic sizes of bituminous. Household consumers are not yet buying heavily, however, while the controversy between Detroit dealers and W. K. Prudden, Michigan fuel administrator, in reference to what constitutes a just margin of profit on domestic coal delivered during the summer, is apparently reflected in a curtailment of deliveries by the dealers. The state fuel commissioner has not yet made known his decision as to a recommendation submitted by the Detroit Board of Commerce asking that a margin of $3 a ton be allowed on bituminous and $2.50 a ton on anthracite. Meanwhile the margin of $2.50 a ton, previously fixed by Mr. Prudden as applying to all domestic coal, remains in effect. Retailers insist their costs range from $2.14 to $2.45 a ton in handling domestic coal, and some of them assert they will go out of business if the margin of $2.50 is maintained.

Anthracite—Incoming shipments of anthracite are not increasing. Records of the secretary of the Detroit and Toledo railroad committee show that the daily average receipts of anthracite since May 1 have been 36 cars, a large drop from the daily average of 56 cars in April. Points in Michigan outside Detroit also show a reduction in supply, the daily average for the state, outside Detroit, amounting to 51 cars this month against 58 during April. Many household consumers who have been endeavoring to provide their winter supply find dealers unable to deliver the coal and declining to book orders for future delivery.

Lake Trade—Shipments of coal by the lakes have considerably diminished since the opening of navigation. The supply arriving at loading docks is not sufficient even for loading ships under carrying contract. Many are going up without cargo.

COLUMBUS

Continued good demand for steam and domestic grades is the chief feature of the Ohio trade. Lake trade is progressing satisfactorily.

Under the influence of a better car supply, excepting on some eastern Ohio railroads, production in Ohio fields has been increased during the past week. In eastern Ohio there is still a shortage in cars and the output is consequently restricted. Demand is good for both domestic and steam grades and little is on the open market. On the whole the tone of the trade is good and prospects are for a continuation of the active conditions.

The lake trade is one of the most active departments of the industry. Every lake shipper is hurrying a large tonnage to the lower lake ports for shipment to the Northwest. The vessel movement is good and as a result there is also a good ore movement. Ice is now all out of the straits and upper passages and there is no interference of that nature. Lake prices are firm at former figures, and the recent reduction of 10c. on the ton will not affect lake coal as practically all has been contracted for at original quotations. Some delay in getting permits from the Ore and Coal Exchange has caused a slow movement in certain thin-vein regions. The lake pool officials are insisting that both thick and thin vein prices be the same.

Domestic trade is active and dealers are busy making deliveries. Retail stocks are not large and every effort is being made to increase them. Householders are buying liberally, even if they cannot get the customary grades. There is little Pocahontas coming into the Columbus market. Considerable West Virginia splint is arriving, however, to make up the deficiency of Pocahontas. The greatest part of the tonnage sold in the domestic trade comes from Hocking Valley and Pomeroy Bend mines. Retail prices so far have not been affected, but a general reduction of 10c. to correspond with the change in mine price is expected.

The steam business is active to the extreme. Buying both for current needs and for storage purposes is going on actively. The larger users have some surplus stocks and are buying rather liberally. Smaller users are increasing their surplus where they have available storage space. Railroads are taking a large tonnage, especially from eastern Ohio mines.

Production is active in most districts as the car supply has been good. This is especially true of the Hocking Valley where the output is estimated at 90 per cent. of normal. In the Pomeroy field the percentage is about the same. In Cambridge and Crooksville production is estimated at 80 to 90 per cent. of normal. Eastern Ohio is still hampered with a shortage of cars and the output is about 65 per cent. of normal.

CINCINNATI

Maximum activity continues in distribution of coal, and dealers' stocks are therefore not rising. Larger receipts would be welcome, but car supply limits shipments.

Deliveries of coal against orders by consumers for storage are continuing at an unprecedented rate, and are limited only by the delivery facilities of dealers on the one hand and the amount of coal available on the other. Receipts are not all that could be desired, especially in view of the increasing volume of shipments to the Northwest, and indications are that unless the car supply increases so as to permit larger production and shipments, not much improvement in the local situation can be expected. However, the trade feels that much has been accomplished in securing orders for so large a proportion of next winter's local requirements, and that even if there should be a shortage next winter it will not in any case affect consumers as severely as they were affected last winter. The storage of coal by industrial consumers is as marked as that by domestic consumers, the accumulation of large quantities of fuel, which are piled in heaps outdoors, is going on at many manufacturing plants in and around Cincinnati. With the continuation of this movement during the entire summer, it is certain that consumers in all classes will start the fall and winter with more coal on hand than ever before.

LOUISVILLE

Second draft is further reducing labor supply, resulting in greater difficulty in operating mines to capacity. Car supply fairly good. Demand for domestic coal good. Steam coal still little draggy.

The greatest obstacle to satisfactory movement of coal during the past month has been the general shortage of labor, which has made it practically impossible for the large mines to operate at anything like capacity in spite of the fact that the demand is good and the car supply fair. Although coal prices have suffered some reductions since stocking up began, few complaints are being heard by the retailers concerning the fact that they paid more for next winter's coal than the present price.

The retail trade is receiving many inquiries for terms on coal stocked for next winter, buyers claiming that it is impossible for them to lay down the case or take care of the bill within 60 days. However, mines are paying off every two weeks, and expect prompt payment from the coal dealers, with the result that they are not in position to grant long terms on winter stocking.

In eastern Kentucky the labor situation is the worst factor, as a good supply of cars is being received. In western Kentucky the mines are operating nearer to capacity than for some time past, but are having more difficulty in obtaining cars than is the case in the eastern section of the state.

The numerous wagon mines which have been operating both in eastern and western Kentucky have been demoralizing labor to some extent. A great deal of good labor is working in these mines, where production cannot begin to compare to that of the large mines in comparison to the actual number of men employed. However, the high price of coal and the profits that are being derived from its sale has enabled hundreds of these little mines to operate, and take labor that would otherwise be producing much more coal in mechanically operated mines.

BIRMINGHAM

Demand strong and steady in the local market. Storing of domestic coal is keeping a satisfactory pace with receipts, which are still much restricted. Distribution of steam-coal supply causes distributing agencies much worry and work. Output shows little betterment.

Domestic consumers continue to evince much interest in acquiring their coal supply for another year, and the demand on dealers is unabated. Records of the Jefferson County Fuel Board show that 16,398

tons of coal passed into the bins of consumers during April, the first month of the coal year, which, in the face of the estimated local yearly requirements of 300,000 tons, might not be considered in an optimistic light but for the fact that in the past storing during the spring and summer months has been very light and the impetus given to the movement this year is gaining force and will likely only be impeded by two factors—financial inability on the part of the consumer and light receipts from the mines. Dealers have contracts and promises for approximately 100,000 net tons of the estimated requirements of 300,000 tons for year ending Mar. 31, 1919.

The distribution of steam coal, on account of the inadequate supply and priority regulations, is proving a vexatious problem, and many industries are unable to operate on a satisfactory basis due to lack of fuel, among which brickmakers are probably the most important. Contractors on the local Federal postoffice are understood to be facing a suspension of work because they cannot get the brick contracted for and which the manufacturers are unable to burn for lack of coal. The Southern Ry. priority order for the current week called for 51 per cent. of the output of operations on its lines in this district, being increased from 46 per cent. for the previous week.

Reports from producing districts are not optimistic as regards increased production. Mine workers continue to absent themselves from their work to an alarming extent, which is proving disastrous both to coal production and coke manufacture.

Coke

CONNELLSVILLE

Labor shortage more in evidence with car supply better. Blast furnaces almost completely supplied with coke.

The visible influence limiting coke production in the Connellsville region is shifting from car supply to labor supply. A number of operators report that on some days they have not sufficient labor to load all the cars furnished, but evidently this means that car supply has increased rather than that labor supply has decreased. Shipments on the whole are increasing slightly from week to week. There are no serious complaints by blast furnacemen of coke shortage, and nearly all the furnaces appear to be well supplied and to be getting out their maximum production of pig iron. There have been a few cases of furnaces asking operators to curtail shipments on contracts. There is a rather limited demand for coke in the open market and operators display some fear that free offerings in the open market would tend to depress prices below the set maximum. Doubtless such fears are well founded, for coke is a particularly difficult commodity to sell when there is not an active demand. While the Connellsville producers may be able to regulate the supply to requirements for the time being, there is a question what will occur when various byproduct plants are put in operation in the next few months. Including the Cleveland plant of the Steel Corporation, which began operations in part three weeks ago, the new byproduct capacity to come in by the end of September promises to represent about 100,000 tons of coke a week. While this will be chiefly by the Steel Corporation, which will merely curtail its production of beehive coke, it will represent the release of some men as well as of some railroad facilities.

The market remains quotable at the set limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over 1-in., $7.30, per net ton at ovens.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended May 18 at 343,270 tons, an increase of 2160 tons.

Middle Western

GENERAL REVIEW

Labor situation serious; another coal famine predicted unless remedy is applied soon.

Mines in all sections of the country report a growing shortage of labor. In some localities where cars are to be had there are not men enough to load out the supply. Although cars continue to be short in various sections, nothing has so absorbed the attention of coal operators during the past week as has the labor problem. One of the principle causes for worry is the indifference of the miners and their desire to throw mines idle on the least provocation. For instance, in any locality where soldiers are leaving on certain days for cantonments the miners declare a holiday and do not report for work. This practice has been freely discussed for some time, but the miners refute all statements by saying there were plenty of men to load all the cars that were to be had and that the mines could not work full time because of the car shortage. Union officials are working hard to remedy the situation.

The car supply has shown some improvement during the past week on many of the large coal-carrying lines. However, some roads continue to be seriously handicapped on account of congestion at the terminals. The demand for domestic size coal continues to be active and householders express a willingness to put in all the coal the dealers will deliver.

CHICAGO

The demand far exceeds the supply; dealers unable to accumulate any stock.

The same condition that prevails throughout the country affects this market. While fine coal has been soft during the past week, there has not been anything like a sufficient supply of lump, egg and nut to take care of orders reaching the dealers. The fact that no coal is being stored confirms the statements that users are taking all the coal that reaches this market. In fact buyers are becoming restless because they cannot get coal as fast as they want it.

Quotations in the Chicago market are as follows, per net ton f. o. b. cars at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Springfield	Carterville	Grundy, La Salle, Bureau and Will
Steam lump	$2.65@2.80	$2.65@2.80	$3.05@3.20	$2.65@2.80	$2.65@2.80	$3.35@3.50

MILWAUKEE

Coal business slow and unsatisfactory. Small dealers have no coal to deliver and consumers are awaiting the summer price schedule. Cargo receipts not up to last year's volume.

The coal situation at Milwaukee is unsatisfactory at the present time, and there is little likelihood that it will be any better until the summer price schedule is announced and dealers are in position to make deliveries. Consumers are slow in booking orders for hard coal, as they know there is not much on hand and they feel that it may be to their advantage to wait. Most of the coal dealers in Milwaukee carry no stocks, but rely upon the dock companies to furnish them with supplies as needed. Thus far the leading dock company, which serves fully 90 per cent. of the small dealers, has received only one cargo of hard coal, and that a very small one; hence all these dealers are practically out of business for the time being.

Cargo receipts up to and including May 25 aggregated 386,835 tons, of which 65,148 tons were hard coal. That slow rail service from the mines is hampering shipments is evidenced by the fact that a 10,000-ton steamer arrived this week with only 4500 tons, preferring to come up with that amount rather than wait for more cars. In May last year Milwaukee received 436,016 tons, of which 63,553 tons were hard coal.

ST. LOUIS

Too much demand for high grade and not enough demand for low grade coal. Railroads still holding off and steam users not storing. Car situation improved on only one road. Domestic consumers continue to hold out for the best, which they cannot get, in preference to the second best, which they could get.

With the railroads buying only what they were compelled to have, and steam users refusing to store, and domestic consumers ordering high grade which they cannot get, at least for some time, and refusing the low grade, of which there is an over-supply, and the mines capable of supplying more even under conditions of car and labor shortage, the demand for Carterville is sustained and the prices unchanged and that for Standard is weaker, with none of the sizes except 6-in. lump bringing the Government prices.

The shortage of cars in the Carterville and Duquoin districts continues, and the scant supplies of coal from those fields received here are used in filling orders that were filed weeks ago. New orders for high grade coal are being received and filed faster than old ones can be filled. Some domestic consumers when told how long they will have to wait for the filling of their orders agree to delivery of low grade, but to most of them winter seems a long way off and they say they will wait. Pressure is being brought to bear by publicity and otherwise to induce them to accept the coal that they can get.

Conditions are approximately normal in the Mount Olive field. In the Standard field there is no improvement in the car supply except that the Louisville & Nashville is in somewhat better shape.

Steam users are doing little storing. They make the excuse that low grade coal deteriorates in storage. In fact the deterioration in six months is slight, but even if it were considerable, the loss it is suggested, would not be as great as if, next winter, a shutdown were necessitated by fuel famine.

The announcement of a reduction of 10c. a ton in the mine price caused an immediate decline in the demand, in the expectation that other reductions might follow.

The circular here is, per net ton f. o. b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.65@3.00	$2.65@2.80	$2.30@2.40
3x6-in. egg	2.65@3.00	2.65@2.80	2.30@2.40

STRUCTURAL MATERIAL—The following are the base prices, f.o.b. mill, Pittsburgh, together with the quotations per 100 lb. from warehouses at the places named:

	Mill, Pittsburgh	New York—Current	New York—1 Year Ago	St. Louis	Chicago
Beams, 3 to 15 in.	$3.00	$4.195	$5.00	$4.27	$4.20
Channels, 3 to 15 in.	3.00	4.195	5.00	4.27	4.20
Angles, 3 to 6 in., ¼ in. thick	3.00	4.195	5.00	4.27	4.20
Tees, 3 in. and larger	3.05	4.245	5.05	4.27	4.25
Plates	3.225	4.45	7.00	4.52	4.45

BAR IRON—Prices in cents per pound at cities named are as follows:

Pittsburgh	St. Louis	Denver	Birmingham
3.50	4.17	4.05	4.38

NAILS—Prices per keg from warehouse in cities named:

	Mill Pittsburgh	St. Louis	Denver	Chicago	Birmingham	San Francisco	Dallas
Wire	$3.50	$4.30	$4.85	$4.25	$4.25	$4.80	$4.75
Cut	3.75	5.30	.....	4.40	....	6.40	.....

TRACK SUPPLIES—The following prices are base per 100 lb. f.o.b. Pittsburgh for carload lots, together with the warehouse prices at the places named:

	Pittsburgh—Current	Cincinnati	Chicago	St. Louis	San Francisco	Birmingham	Denver
Standard railroad spikes 5/16-in. and larger	$3.90	$6.00	$4.50	$6.25	$6.25	$5.30	$5.00
Track bolts	4.90	8.90	5.50	6.40	7.45	8.00	6.00
Standard section angle bars	3.25	....	4.45	....	4.90	....	4.30

COLD DRAWN STEEL SHAFTING—From warehouse to consumers requiring fair-sized lots, the following discounts hold:

Cincinnati	Cleveland	Chicago	St. Louis	Denver	Birmingham
17½%	List	+10%	+10%	+35%	+30%

HORSE AND MULE SHOES—Warehouse prices per 100 lb. in cities named:

	Mill Pittsburgh	Cincinnati	Chicago	St. Louis	Denver	Birmingham
Straight	$5.25	$6.50	$6.50	$6.25	$7.50	$7.00
Assorted	5.40	6.50	6.50–7.00	6.40	7.75	7.25

Cincinnati—Horseshoe nails sell for $4.50 to $5 per 25-lb. box

CAST-IRON PIPE—The following are prices per net ton for carload lots:

	New York—Current	New York—1-Month Ago	New York—One Year Ago	Chicago	St. Louis	San Francisco	Dallas
4 in.	$58.35	$58.35	$58.00	$57.55	$57.00	$65.00	$61.00
6 in. and over	55.35	55.35	55.50	54.55	54.00	62.00	58.00

Gas pipe and 16-ft. lengths are $1 per ton extra.

STEEL RAILS—The following quotations are per ton f.o.b. Pittsburgh and Chicago for carload or larger lots. For less than carload lots 5c. per 100 lb. is charged extra:

	Pittsburgh—Current	Pittsburgh—One Year Ago	Chicago—Current	Chicago—One Year Ago
Standard Bessemer rails	$63.00	$38.00	$63.00	$38.00
Standard openhearth rails	65.00	40.00	65.00	40.00
Light rails, 8 to 10 lb.	*3.135 (100 lb.)	58.00	*3.135 (100 lb.)	53.00
Light rails, 12 to 14 lb.	*3.09 (100 lb.)	57.00	*3.09 (100 lb.)	54.00
Light rails, 25 to 45 lb.	*3.00 (100 lb.)	53.00	*3.00 (100 lb.)	52.00

* Government price per 100 lb.

OLD MATERIAL—The prices following are per gross ton paid to dealers and producers in New York. In Chicago and St. Louis the quotations are per net ton and cover delivery at the buyer's works, including freight transfer charges:

	New York	Chicago	St. Louis
No. 1 railroad wrought	$31.50	$29.75	$28.50
Stove plate	22.50	23.00	20.00
No. 1 machinery cast	34.00	26.50	21.50
Machine shop turnings	16.00	15.50	15.50
Cast borings	16.00	15.75	15.00
Railroad malleable cast	31.00	29.50	26.50

COAL BIT STEEL—Warehouse price per pound is as follows:

New York	Cincinnati	Birmingham	St. Louis	Denver
$0.12	$0.16½	$0.18	$0.18	$0.17

DRILL STEEL—Warehouse price per pound:

	New York	St. Louis	Birmingham
Solid		15c.	15c.
Hollow		25c.	....

PIPE—The following discounts are for carload lots f.o.b. Pittsburgh; basing card of Nov. 6, 1917, for steel pipe and for iron pipe:

BUTT WELD

Steel Inches	Black	Galvanized	Iron Inches	Black	Galvanized

Commercial	50.00	35.00	22.00	20.75	22.00	25.00

HOSE—Following are prices of various classes of hose:

Fire

	50-Ft. Lengths
Underwriters' 2½-in	75c. per ft.
Common, 2½-in	40%

Air

	First Grade	Second Grade	Third Grade
¾-in. per ft	$0.55	$0.30	$0.25

Steam—Discounts from list

First grade 30% Second grade 30–5% Third grade 40–10%

LEATHER BELTING—Present discounts from list in cities named:

	Medium Grade	Heavy Grade
St. Louis	40+5%	35%
Denver	35%	30%
Birmingham	35%	40%
Chicago	30—10%	40—5%
Cincinnati	40—10%	40%

RAWHIDE LACING—40% off list.

PACKING—Prices per pound:

Rubber and duck for low-pressure steam	$0.90
Asbestos for high-pressure steam	1.65
Duck and rubber for piston packing	1.00
Flax, regular	.90
Flax, waterproofed	1.10
Compressed asbestos sheet	1.00
Wire insertion asbestos sheet	1.20
Rubber sheet	.60
Rubber sheet, wire insertion	.90
Rubber sheet, duck insertion	.50
Rubber sheet, cloth insertion	.25
Asbestos packing, twisted or braided, and graphited, for valve stems and stuffing boxes	1.10
Asbestos wick, ½- and 1-lb. balls	.65 to .70

WIRE ROPE—Discounts from list price on regular grades of bright and galvanized are as follows:

	New York and St. Louis
Galvanized iron rigging	+20%
Galvanized cast steel rigging	List
Bright plain rigging	30%
Bright cast steel	17½%
Bright iron and iron tiller	5%

MANILA ROPE—For rope smaller than ⅝-in. the price is ½ to 2c. extra; while for quantities amounting to less than 600 ft. there is an extra charge of 1c. The number of feet per pound for the various sizes is as follows: ⅝-in., 8 ft.; ¾-in., 6; ⅞-in., 4½; 1 in., 3½; 1⅛-in., 2 ft. 10 in.; 1¼-in., 2 ft. 4 in. Following is price per pound for ⅝-in. and larger, in 1200-ft. coils:

Boston	$0.34½	Atlanta	$0.36
New York	.33½	Denver	.35½
Cincinnati	.33¼	Kansas City	.34
Chicago	.32½	New Orleans	.33
St. Paul	.34	Seattle	.33½
San Francisco	.31	St. Louis	.33
Pittsburgh	.36	Los Angeles	.32
Birmingham	.37		

PIPE AND BOILER COVERING—Below are discounts and part of standard lists:

PIPE COVERING

Pipe Size	Standard List Per Lin. Ft.
1-in.	$0.27
2-in.	.36
6-in.	.80
4-in.	.60
3-in.	.45
8-in.	1.10
10-in.	1.30

BLOCKS AND SHEETS

Thickness	Price per Sq.Ft.
½-in.	$0.27
1 -in.	.30
1½-in.	.45

COMMON BRICK—The prices per 1000 in cargo or carload lots are as follows:

Cincinnati	$12–15.50	Birmingham	$13.25–15.00
St. Louis	14.00	Denver	8.50

WIRING SUPPLIES—New York prices for tape and solder are as follows:

Friction tape, ½ lb. rolls	35c. per lb.
Rubber tape, ½-lb. rolls	45c. per lb.
Wire solder, 50-lb. pools	45c. per lb.
Soldering paste, 1-lb. cans	50c. per lb.

PREPARED ROOFINGS—Standard grade rubbered surface, complete with nails and cement, costs per square as follows in New York, St. Louis, Chicago and San Francisco.

	1-Ply		2-Ply		3-Ply	
	C.I.	L.C.I.	C.I.	L.C.I.	C.I.	L.C.I.
No. 1 grade	$1.30	$1.55	$1.60	$1.75	$1.90	$2.05
No. 2 grade	1.15	1.30	1.45	1.60	1.75	1.90

Asbestos asphalt saturated felt (14 lb. per square) costs $5.35 per 100 lb.

Slate-surfaced roofing (red and green) in rolls of 108 sq.ft. costs $1.95 per roll in carload lots and $2.20 for smaller quantities.

Shingles, red and green slate finish cost $5.25 per square in carloads, $5.50 in smaller quantities, in Philadelphia.

ROOFING MATERIALS—Prices per ton f.o.b. New York or Chicago:

	Carload Lots	Less than Carload Lots
Tarfelt (14 lb. per square of 100 sq. ft.)	64	65
Tar pitch (in 400-lb. bbl.)	20	21
Asphalt pitch (in barrels)	35	40
Asphalt felt	72.50	77.50

HOLLOW TILE—The price per 1000 in carload lots f.o.b. mine is as follows:

	4 x 12 x 12	8 x 12 x 12
St. Louis	$80.00	$137.00
Chicago	79.00	137.00
Denver, per ton	11.00	200.00
Kansas City	75.00	140.00
St. Paul	56.00	110.00
Boston	80.00	150.00
Birmingham	65.20	122.25
Cincinnati	68.00	129.00
Pittsburgh	86.50	147.10

LUMBER—Price of yellow pine per M in carload lots:

	1-in. Rough 10 In. x 16 Ft.	2-In. T. and G. 10 In. x 16 Ft.	8 x 8 In. x 20 Ft.
St. Louis	$40.00	$31.00	$38.00
Birmingham	28.00	30.00	28.00
Pittsburgh	48.50	48–50	50–55
Denver	40.00	42.00	42.50
Cincinnati	45.00	44.00	39.00

STEEL SHEETS—The following are the prices in cents per pound from jobbers' warehouse at the cities named:

FREIGHT RATES—On finished steel products in the Pittsburgh district including plates, structural shapes, merchant steel, bars, pipe fittings, plain and galvanized wire nails, rivets, spikes, bolts, flat sheets (except planished), chains, etc., the following freight rates are effective in cents per 100 lb.:

Boston	21.5	Minneapolis	35.5
Buffalo	11.6	New Orleans	30.7
Chicago	21.5	New York	19.5
Cincinnati	18.5	Philadelphia	18.5
Cleveland	13.5	St. Louis	27.0
Denver	79.0	St. Paul	40.0
Kansas City	47.0	Pacific Coast (all rail)	100.0

COAL AGE

Volume 13 NEW YORK, JUNE 8, 1918 Number 23

Organizing the Coal Industry

By Floyd W. Parsons

MANY people have believed that the production and national distribution of coal could not be systematized. There was good reason for entertaining this idea, because no commodity enjoys wider use or comes more generally into daily life than does the fuel production of our 8000 mines.

The Fuel Administration in Washington, however, some months ago determined to know just where all the coal goes, and this ambitious plan is on the way to a happy and useful realization. Very soon all consignees who receive as much as one car of coal per month, or approximately 500 tons per year, will be required to report regularly all receipts, disbursements and consumption of fuel.

At the commencement, the Fuel Administration will receive about 100,000 reports weekly. This will cover approximately 90 per cent. of our production. The remaining 10 per cent. will be cataloged a few weeks later.

Before snow flies again, Dr. Garfield and his associates will have definite figures showing the production and consumption of coal in every zone, and these data will enable them to shift coal promptly from one region where there is an abundance to other districts where a shortage exists.

With an equitable car supply, and such complete data covering fuel requirements, it is now a certainty that we will have far greater efficiency in coal distribution than ever before. It is not so likely that one region will have a feast and another a famine.

The Government will have absolute control of the Nation's industries through its power to dispense fuel. Less essential industries will not get coal that war plants need. It is because of this fact that hundreds of businesses must either seriously curtail output or substitute war work for peace work.

Every 3-in. shell that we fire on the battle front in France means a consumption of 80 lb. of coal. When artillery bombardments are intense, it is not unusual to fire enough shells at a single point to consume 7000 tons of coal per hour. One recent battle lasting several months consumed more coal than we will produce in all of the mines of Tennessee this year. To build one 8000-ton cargo ship requires 16,000 tons of coal. We plan to build hundreds of these ships this year, so it is evident that this work will demand a large quantity of fuel.

War is a new business with us, but it is already our chief business. We must adapt our lives to a new order of things, and to this end let us supply the Nation with sufficient coal to avoid any lack in the necessary sinews of war. This is no ordinary occasion, and we can only win by putting forth the last ounce of energy that is in us.

IDEAS AND SUGGESTIONS

Combination Signal System

BY ELECTRICAL ENGINEER
Lafayette, Colo.

The use of primary batteries for operating signal bells is common practice; alternating current at 110 volts is not considered successful unless the bells are specially wound; the use of direct current at various

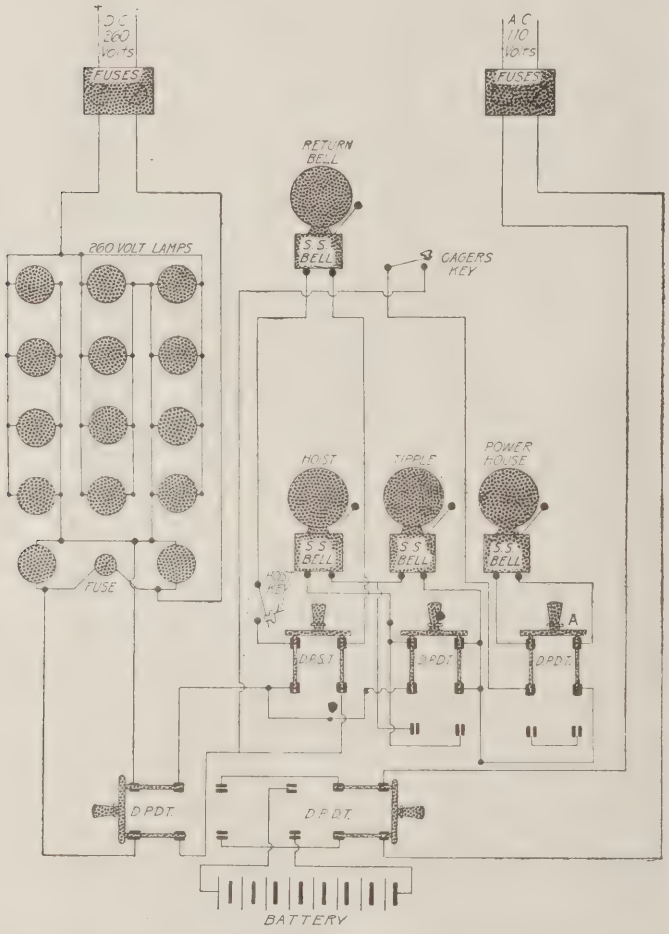

FIG. 1. SIGNAL-BELL SYSTEM THAT OPERATES ON ONE OF THREE SOURCES OF SUPPLY

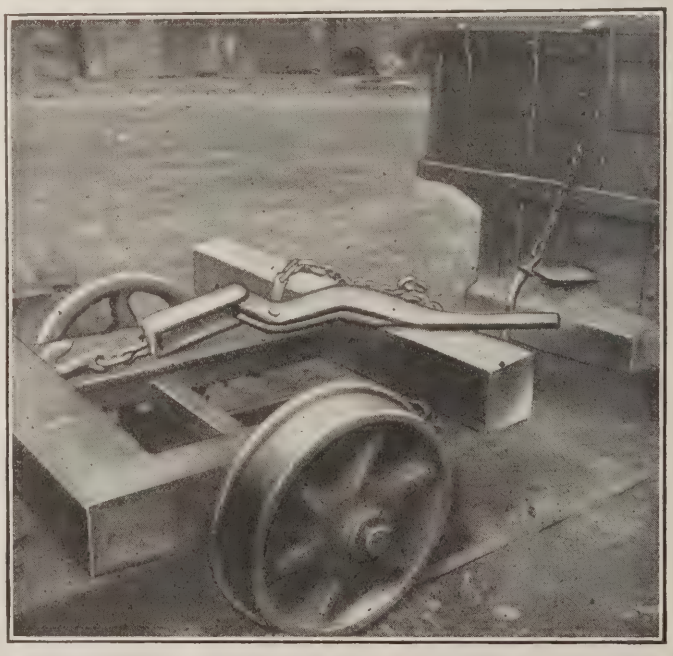
voltages through a set of lamps is in use to some extent. A signal-bell system that is arranged to work on any one of these three sources of supply by simply changing certain switches is especially interesting. Such an arrangement and one that is working successfully, is shown in Fig. 1.

This system has been in successful operation for years at one of the large coal mines in Colorado. The mine in question is a shaft, and the signal board is located in the hoistroom. The bell and the ringing key are also located in the hoistroom. Another bell is located at the top of the tipple where the cage and cars of coal land. One bell and a strap key for signaling is located at the bottom of the shaft for the use of the cager. Another bell is placed in the power house. This is generally cut out of circuit by the switch *A* and is only used when the engineer who attends to the power house as well as the running of the hoist is attending to that part of his duties. This bell will then warn him when he is wanted at the hoist.

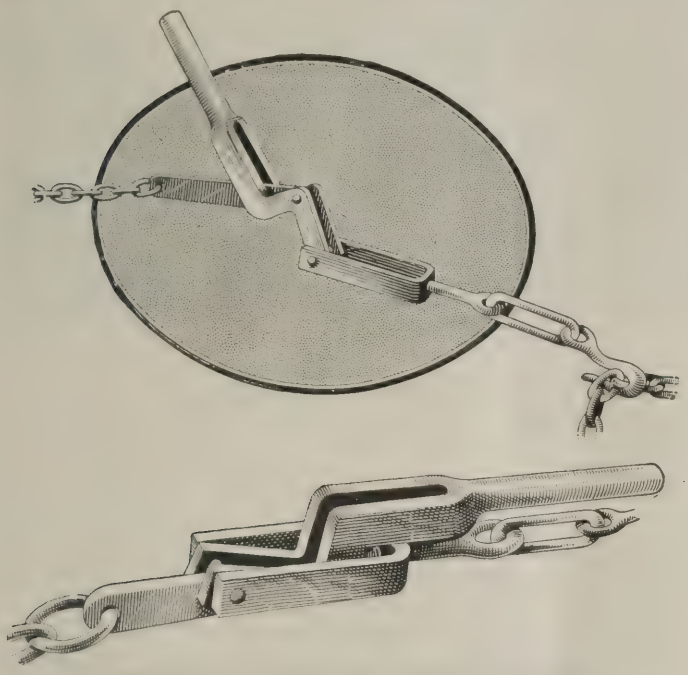


The bells used are all single stroke and are fitted with 8 and 10-in. gongs. The electro-magnets are wound with No. 18 double cotton-covered magnet wire. The results obtained are a quick, clear ring with each pressure on the keys. The system generally in use is shown in Fig. 1. The system is here shown operating on direct current.

Self-Locking Pipe and Timber Binder for Slope Car

BY R. W. MAYER
Connellsville, Penn.

The American Zinc and Chemical Co., at Burgettstown, Penn., handles rails and pipes in its mine on a special car which was built for that purpose. This car has no box, only a framed platform on the axles of the car. A special binder is provided, to hold the load of pipes or rails in place on the car, the load being bound at the front and rear of the car.



The binder proper consists of a self-locking lever carrying a grab hook. This grab hook is attached to the lower end of a clevis by means of a link and swivel; a slotted and properly bent hand lever is attached to the open end of this clevis by means of bolts or rivets; at the first bend of the lever a strap link connects the

BINDER HOLDS LOAD OF PIPES AND RAILS IN PLACE ON A SPECIALLY BUILT CAR

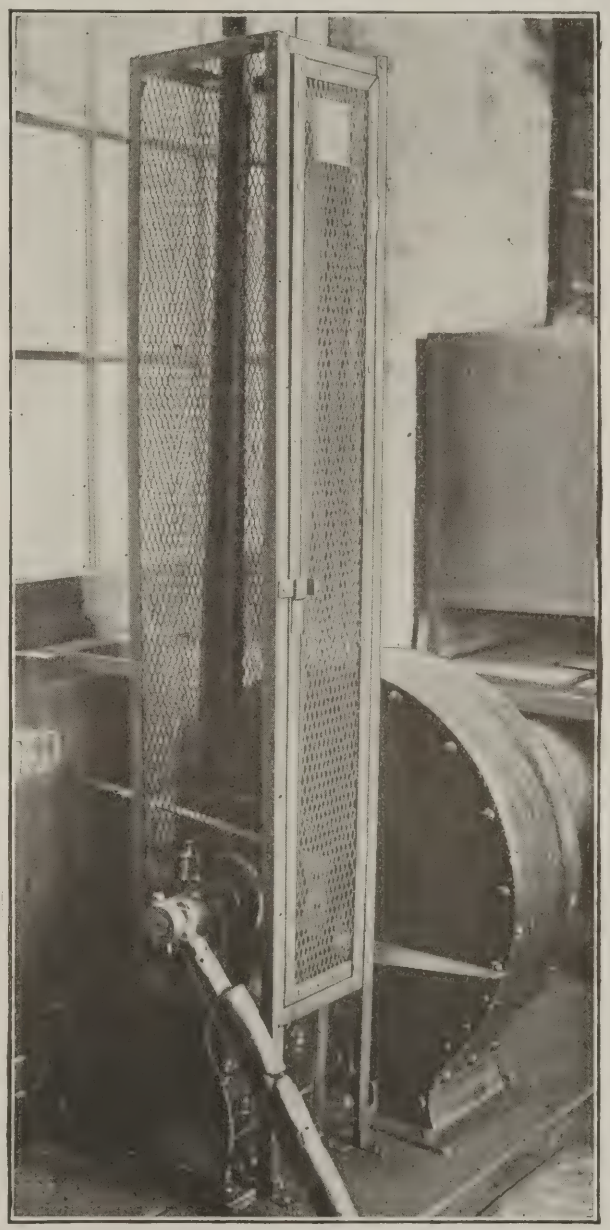
lever to the chain attached to one corner of the truck; the lever terminates in a suitable hand hold. The link last mentioned is long enough to reach from its point of attachment to beyond the end of the lever and is free to move between the two lever prongs. The clevis also is sufficiently long and wide to permit the lever at the bent portion to swing between its sides.

In operation, after the load of pipe, rails, pit lumber, or other material has been placed upon the truck, the

DETAILS OF PIPE AND TIMBER BINDER

chain from one corner of the car is brought up and over the load. The chain from the opposite side, as has been stated, carries at its extremity the binder terminating in the grab hook. This hook is attached to any convenient link of the opposite chain and the hand lever then moved downward toward the clevis. This, of course, shortens the loop of chain encircling the load, and when the bent portion of the lever passes the center line of the clevis the device becomes self-locked. The load is thus securely bound to the truck. When it is desired to remove the load a pull upward on the lever unlocks the binding so that the grab hook may be unfastened.

Bell-Ringing Transformers to Serve Signaling Devices



By H. O. Gra ·am

Any reasonable number of electric signaling bells or annunciators may be served from one bell-ringing transformer, provided the circuits are so arranged that not many of the signaling devices will be taking energy through the transformer at the same instant. For example, the ordinary small bell-ringing transformers that are used in the average house-wiring installation will usually satisfactorily serve simultaneously two or three electric bells, or devices requiring an approximately equivalent amount of energy. Larger bell-ringing transformers can be purchased that will serve simultaneously six, seven, or even possibly a dozen ordinary signaling devices.

Convenient Machine Guards

The guarding of belts, flywheels and other moving machine parts has received considerable attention at coal mines and various industrial plants during the past few years. The materials from which guards have been constructed have ranged from pine boards to steel or iron castings. The ideal guard, however, is one that is light, strong, easily removable either in whole or in part, and does not shut off or seriously obstruct the view of the moving parts shielded.

The accompanying illustration shows one of the most efficient types of guards yet devised. It consists of an angle-iron frame over which expanded metal is stretched

EFFICIENT TYPE OF MACHINE GUARD

and fastened securely. It will be noticed that one side of the guard here shown is a hinged door that may be opened easily, thus affording ready access to the belt that is inclosed. The journal oil cups are outside of the guard. The machine may thus be oiled and inspected without disturbing the belt guard. The guard may be entirely removed at any time should occasion require that this be done.

Coal Tipple for Small Operations

By H. B. MOSLEY
Philadelphia, Penn.

SYNOPSIS — *An extremely simple and inexpensive tipple for run-of-mine coal is here described. This consists essentially of a dump at ground or drift level and a scraper conveyor elevating and conveying the coal across a trolley track and highway and discharging it into railroad cars. A few slight changes would enable this tipple to make two or more sizes.*

BECAUSE of the increased demand for coal, the general shortage of labor and the Government-fixed price, it has become essential for the small operators to work on the most efficient basis possible and with the smallest amount of help.

The purpose of this article is to describe to some extent, at least, means by which the small operator (who cannot afford or who is not warranted in the expenditure of a large sum of money for a modern coal tipple) can handle his coal with the minimum amount of labor and at the least cost.

At the Paul & Dailey Coal Co., Western Port, Md., where coal is found outcropping in various beds up the hillside, a system for the mechanical handling of coal from mine cars to railroad cars has recently been installed and found quite satisfactory, not only in operation and maintenance, but in the man power saved.

At this mine mules are used to pull cars of coal to the mouth of the drift. This is driven in the lower coal bed, known as the "split six," being 6 ft. of fine grade bituminous coal split in the middle by a rock binder 1 ft. thick. From the mouth of the mine the cars are taken over a scale and weighed. First, however, the mules are unhitched and taken back into the mine.

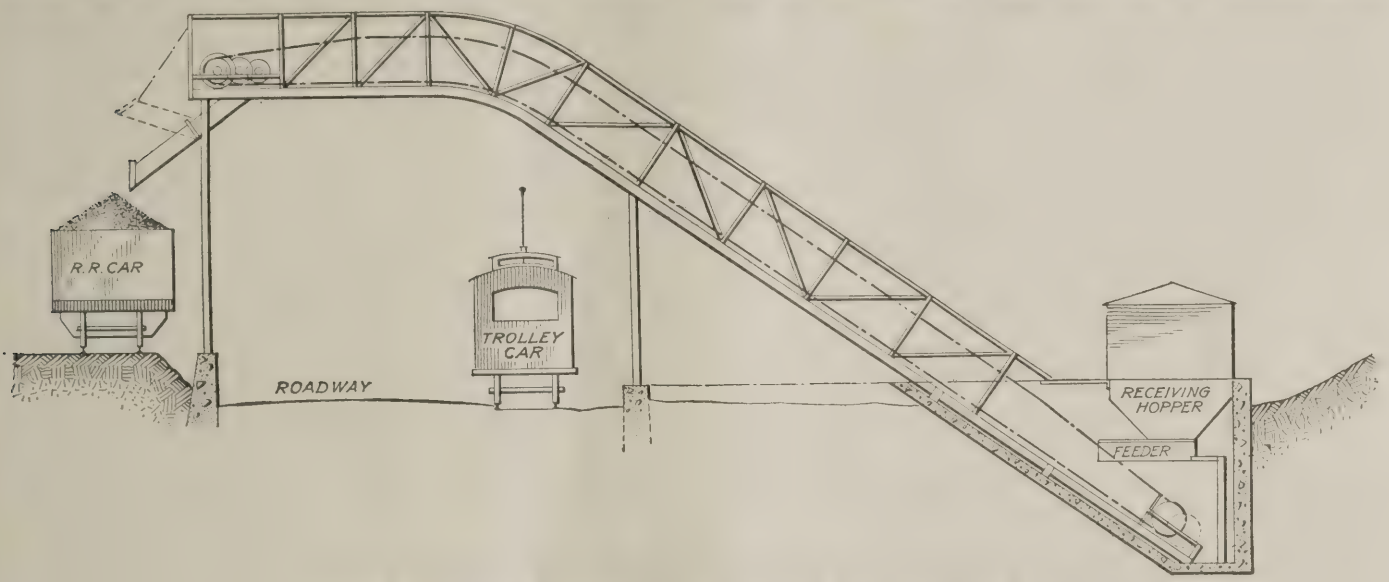
After the cars are weighed they are sent down a slight incline and discharged by means of an automatic dump into a receiving hopper. The empty cars are switched to another track and sent down grade to the entrance of the mine again. It was the original intention to have the scale housed in the same building with the receiving hopper and automatic dump, but this meant that both loaded and empty cars would have to pass over the scale, so the other method was adopted.

The receiving hopper is 10 x 12 ft. in plan and built of $\frac{1}{4}$-in. steel plate, securely stiffened with angles. This hopper is attached to the sides of a concrete pit by bolts set in the concrete. The housing over the hopper and the automatic dumper is of light steel, "angle-iron" construction, sheathed with No. 22 gage galvanized corrugated iron.

From the receiving hopper the coal is fed into a flight conveyor by a reciprocating feeder. This feeder consists of $\frac{3}{16}$-in. side plates 18 in. high, attached to the outlet of the hopper, and has a $\frac{1}{4}$-in. plate bottom to which is attached shafts and rollers on which it reciprocates. These rollers travel on angle-iron tracks which are hung from the feeder sides by cast-iron brackets. The feeder plate is driven by means of a wristplate and pin and eccentric rods which are actuated by a substantial chain drive from the tail end of the conveyor.

The conveyor is built of two strands of 9-in. pitch steel roller chain having $\frac{3}{8}$ x $2\frac{1}{4}$-in. side bars, $\frac{7}{8}$-in. pins and 3-in. hard cast-iron rollers at each joint, between which are attached at 18-in. intervals $\frac{3}{16}$-in. steel plate flights, 10 in. high by 20 in. wide. This chain has an ultimate strength of 50,000 lb., but is rated at 2300 lb. working strength by the builders. The flights are built of a single piece of plate flanged back on both sides and securely attached to the chain. This makes a rigid and serviceable flight.

The carrying run of the conveyor operates in a steel trough having 9 in. x $13\frac{1}{4}$-in. channel sides and $\frac{3}{16}$-in. plate steel bottom. The bottom plates are bolted in place and in case of appreciable wear new ones can readily be substituted. Angles 4 x 3 x $\frac{5}{16}$ in. are



countersunk and riveted to the upper flanges of the trough channels for the chains to roll upon, also to form part of the bridge which spans the roadway. The return run of the conveyor also travels on 4 x 3 x $\frac{5}{16}$-in. angles, which serve as the upper chord of the conveyor bridge. All shafts of the conveyor were designed for both torsion and bending, allowing a combined unit stress of not over 11,000 lb. Bearings are of the rigid babbitted type, fitted with compression grease cups.

A 10-hp., 1100-r.p.m., Westinghouse, constant-speed, continuous service, open-type motor is connected to the conveyor countershaft by means of a cast-iron cut spur gear and brass-bound rawhide motor pinion. A light steel-plate motor box was used to cover the motor and automatic starter, while gear guards of the same material surround all gearing to protect the attendant.

Push-button stations for controlling the conveyor are located at the conveyor receiving hopper, at the discharge chute and at the mouth of the mine. The conveyor carries the coal up an incline of 30 deg. and horizontally over a highway at a clearance height of 21 ft. from the crown of the road and discharges it into a chute which deposits the coal in railroad cars at the rate of 70 tons per hour. This fills the average size of car in about 45 minutes.

The discharge chute is 18 in. square, built of $\frac{1}{4}$-in. steel plate, and is hinged to fold up in order to give necessary railroad clearance. An ample counterweight is provided so as to make the raising and lowering of the chute simple and easy.

From the ground a footwalk 24 in. wide, built of 2-in. plank, is provided extending up the incline and along the horizontal portion of the conveyor on one side. Wood cleats are furnished on the inclined portion to assist the attendant in walking up. A platform is provided around the driving machinery to give easy access to the lubricating grease cups. A double run handrail 42 in. high, built of 1$\frac{1}{4}$-in. black pipe, incloses the footwalk and

CROSS-SECTION OF THE RECEIVING HOPPER AND CONVEYOR LINE

SIDE VIEW OF TIPPLE, SHOWING ITS GREAT SIMPLICITY

platform on the outer side. This layout shows what can be done for the small operator who is at all times hard pressed for labor to transfer coal from mine cars to railroad cars. The equipment would be even less expensive if there were no highway to carry the material across, and it was only necessary to elevate the coal to railroad cars. Again, if the cars are far away, it is an easy matter to lengthen the conveyor and supporting bridge.

If it is desired to screen the coal before loading it for shipment, the trough bottom plate may be perforated to the desired size and all material passing through the screen plate would enter a screenings hopper from which it would be drawn by a gate at the bottom. A screen of this type can also be arranged in the chute to the railroad cars, this being a favorite method of finally screening all breeze from coke before it goes to the ultimate consumer.

Many modifications of a plant of this type can be worked out and all be thoroughly practical. It is therefore believed that the small operator will soon appreciate the opportunity for mechanical handling equipment for coal after it has reached the mouth of the mine. This will relieve a large number of men for work in the mines themselves, or at some other place where they are more urgently needed.

The complete equipment described was furnished by the R. H. Beaumont Co., of Philadelphia, Penn., which specializes in coal, coke, and ash handling equipment.

Educating the Small Mine Owner to the Value of Engineering

By O. H. Hampsch
Washington, D. C.

The matter of engineering in small mines is often a neglected factor. I say small mines, for most of the larger companies have one or more engineers whose work it is to look after and solve the engineering problems that arise. But by many of the smaller companies it is deemed an unnecessary luxury to hire an engineer.

It is quite true that many small companies may not be justified in keeping an engineer when development is slow and a small tonnage is produced, but often such companies may jointly keep a man, allotting so much of his time to each mine (this amount depending upon the speed of development) or using his services at regular intervals.

The value of keeping entries and rooms on sights needs no argument, for I think anyone will agree that it is worth the time and money spent. Such a procedure results not only in maximum recovery, smaller air resistance and compactness of mine workings, but regular and even pillar supports tend to lessen squeezes and loss of territory and increase the value of a mine. One's opinion of crooked entries and diverging rooms in a mine is the same as his opinion of a town or city with crooked and winding streets and lots to correspond. Many operators consider the state survey that is required by law annually or semi-annually a sufficient amount of engineering, and many would not do even this if it was not compulsory. This reminds one of surveying a railroad after it is built.

In most cases the majority of these problems are taken care of partly by foremen in charge with the aid of a Brunton pocket compass. This is wholly inadequate for accurate work because of rails, pipes, cars, etc., which in every case will cause an erroneous reading or bearing and render it impossible to run straight entries or compute with accuracy the distance to a boundary line. Accurate transit or vernier surveys of a coal field, and tied to a complete underground survey, is the only kind that should hold in a dispute or lawsuit over boundary lines of relative location of underground workings. Many a mine owner has been agreeably or disagreeably surprised to find just where he actually is, often having mined for several years as a mole burrows through the earth, taking the line of least resistance. The cost of an encroached property or a lawsuit springing therefrom, not considering the ill feeling between land owner and operator, would often pay for the services of an engineer for a year or more.

On main entries and other passages where haulage is continuous or heavy, profiles should be run and plotted. From these the exact locations of hills or sags in the road bed and necessary cuts or fills for an ideal grade can be determined. This is quite a factor in haulage and amounts to much, whether the haulage be by mule or motor power. The user of profiles where entries are wet or water flows is of considerable value for ditching or determining the location of pumps and sumps. Often by careful grading a gravity flow can be obtained.

Entries driven off main entries or at a point where two entries diverge should be started on a curve ranging from 50 to 150 ft. in radius, depending upon the speed and kind of haulage. This eliminates considerable friction, makes an easier pull for haulage power and decreases the danger of loaded cars leaving the tracks. Care should be taken as the underground workings progress to watch the location of wells, springs, creeks, etc., especially when there is but little cover overhead, in order that these do not affect the mine through leakage; also the location of important or heavy buildings, railroad tracks and the like, leaving, if necessary, a reserve block of coal to support them.

I believe that as mineral rights become more valuable and efforts are made to improve the methods of mining, the value of starting and developing a mine on well planned, sound engineering principles will be more and more realized; and the day will come when an engineer will be as necessary to a mine as to a railroad or city.

Antiseptic Value of Peat

Peat produced by the decomposition of sphagnum moss is so antiseptic and absorbent that it is used as a dressing for wounds and is an excellent substitute for medicated cotton. This fact was recognized many years ago in Europe, where sphagnum peat is now extensively used in preparing surgical dressings. According to Professor Soper, who has made a detailed study of the peat deposits in northern United States, there are many square miles of sphagnum bog in the northern counties of Minnesota, Wisconsin and Michigan that would supply material suitable for antiseptic applications. It will not be necessary to incur the expense of deep excavation, for immense quantities of sphagnum can be taken from the upper parts of the deposits. Sphagnum peat is also abundant in Maine, and some is found in New York and Pennsylvania.

Exhaust-Steam Turbine Installations at Coal Mines—I

By E. I. ROBERTS
Cardiff, Alberta

SYNOPSIS—*An opportunity for making a considerable saving in fuel consumption exists at many coal-mining plants in the shape of a low-pressure turbine drawing its steam supply from other units. Such a machine of course necessitates the installation of considerable auxiliary apparatus, but the economies possible sometimes amount to as much as 100 per cent.; that is, the power reclaimed from exhaust steam sometimes equals the power generated by the live steam.*

THROUGH the conditions brought on by the war, and a closer adherence to efficiency methods, the attitude of coal companies with reference to the coal burned at their own plants is changing. In the past the majority of the operators considered that mine-run, nut or even egg coal cost them nothing and, in consequence, any of these sizes were used at the plant. The boilers were usually hand-fired, and often this was done by men who were good coal shovelers but poor firemen.

The coal was moved by hand into the boiler house and there unloaded, again by manual labor. All of the ashes were loaded and taken from the boiler house and dumped by man-power. Still the operator considered that the coal cost him nothing. Today we see a change. The tendency is to use the smallest sizes, to burn this with stokers, to handle the coal to the boiler plant with conveyors, and to distribute the ashes with the same appliances. Some coal companies go still farther. They install water-tube boilers, water-softening plants, superheaters and turbines, so that their mines may be electrified as far as possible. These latter features have been, and are still, considered in some fields as unnecessary refinements at any place except a large power plant. There is one method, however, which would at once make a decided gain on the profit side of the balance sheet of any average mine power plant. This is the installation of an exhaust-steam turbine unit. It is with this latter piece of apparatus that this article deals.

Considering the charts, Fig. 1, which show the heat used from the coal in plants employing ordinary engines alone, and again, using exhaust-steam turbines in addition, it will be seen that for the same fuel value the power produced is increased 70 per cent. Considering also that the total quantity of heat available from coal is around 9 to 10 per cent. at the average coal plant, the extra saving is an appreciable factor to any coal company.

In the first case let us assume that steam is to be drawn from high-speed reciprocating units, using steam at the rate of 27 lb. per i.hp.-hr., while the rating of the exhaust steam turbine is 30 lb. per i.hp.-hr. Further we will assume that the high-speed units consume 15,000 lb. of steam per hour. This gives $\frac{15,000}{27} = 555$ hp. Of this 15,000 lb. of steam used we allow 20 per cent. lost in condensation, and elsewhere, thus giving us 12,000 lb. available for the turbine. This gives $\frac{12,000}{30} =$ 400 hp. From this we subtract 7 per cent. for the driving of auxiliaries, for forming the vacuum for the turbine. This amounts to 28 hp., which leaves 372 hp. net from the turbine, or an increase of 67 per cent. in power derived from the same quantity of steam generated by the boilers.

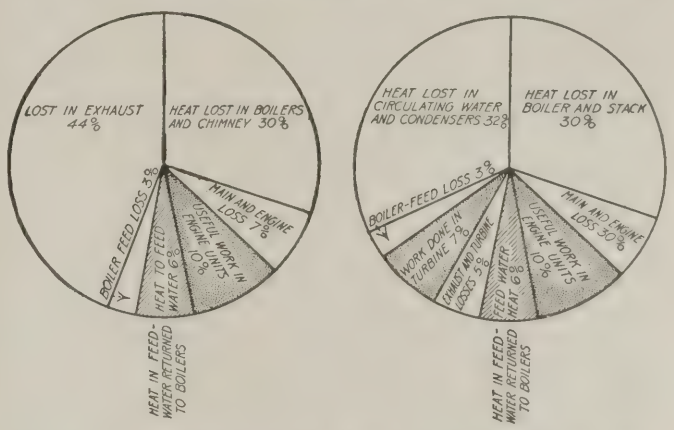


FIG. 1. UTILIZATION OF HEAT IN POWER PLANTS

If the hoist, steam pumps and general steam-consuming units around the mine are of the simple noncondensing engine type and less economical in steam consumption than has been assumed above, a still further saving can usually be made by the installation of a unit using the exhaust steam. This additional saving may at times amount to as much as 100 per cent.

In the second case let us assume a plant uses saturated steam at the rate of 40 lb. per i.hp.-hr., and the turbine at the rate of 30 lb. per i.hp.-hr., and that 20,000 lb. per hour is the quantity used in the simple noncondensing units. Then allowing 20 per cent. for condensation and loss in cylinders, piping, etc., 16,000 lb. will be available for the turbine. The power developed by the simple noncondensing units is $\frac{20,000}{40} = 500$ hp., and that developed by the turbine $\frac{16,000}{30} = 533$ hp., subtracting from this 533 hp., 7 per cent. for the driving of auxiliaries, or 37.3 hp. for rough figuring, say 37 hp., leaves 496 hp. from the unit using the exhaust steam. The total increase over and above the live-steam units is then 99.3 per cent., or roughly 100 per cent. increase in power for the same quantity of steam generated by the boilers.

It is in existing plants that the exhaust-steam unit will give the most advantage. New plants are being

designed and equipped with modern appliances to consume steam economically. Furthermore, during the early development of the mine insufficient exhaust steam is supplied by the live-steam units to operate a turbine; unless it is of the mixed pressure type, wherein live steam may be used during the periods when there is no exhaust steam.

The operation of a unit of this type, together with the condensers and auxiliary equipment, if properly installed is as simple as that of any reciprocating engine. It occupies less space, and if so installed that water cannot enter with the steam and dust is excluded from the bearings, is much cheaper in maintenance. There are other advantages to this type of unit. Thus, when a surface condenser is used with the turbine the condensed water may be returned to the boilers. This in itself is an item which covers a large ground at a mine plant. The cleaning of boilers, the bagging of sheets and the purchase of compound for the boilers in which mine water is used is an ever-present source of trouble while foaming and priming are constant dangers; also the corroding and pitting of feed-water pipes and boiler fixtures are a continuous source of expense. The returning of the condensate to the boilers practically eliminates these difficulties.

Even at plants employing condensing units there is a field for the exhaust-steam turbine. The exhaust unit being placed between the high-pressure machine and the condenser will enable at least 2 in. more of vacuum to be carried at the condenser, and this means about 10 per cent. more power from the steam. It is impossible to increase the vacuum to this extent with the known reciprocating engines, as air leakage prevents a vacuum higher than about 26 in. referred to a 30-in. barometer.

Passing from the preliminary considerations to the design and erection of such a unit at a coal-mining plant, we will consider in succession the steam available, the turbine specifications and the auxiliaries that are necessary for a 500-kw. mixed-pressure turbine driving a direct-current generator of this size.

We will first detail the equipment, from which data were taken for the actual driving of a unit of this size. This is shown in the following table:

Unit	Size	Cutoff	Speed	Hp.	Time Operating at	Per Cent. Load	Quantity Steam, Lb.
Hoist (twin)....	24x36	5/8	90	510	3/10 (see other details)	100	12,240
Shaker engine...	14x18	1/2	80	71.5	Full time	66	1,920
Roller screen engine.....	10x20	1/2	75	38	75 per cent.	75	860
Fan engine.....	14x20	1/2	70	62.5	100 per cent.	87	2,200
Shop engine.....	5x10	3/8	175	10	100 per cent.	75	300
Pump No. 1....	14x18	1/1	250 per	gal. min.	250-ft. head	100	1,000
Pump No. 2....	12x 7	1/1	200 per	gal. min.	40 ft. head	100	120
Holmes car lift..	14x18	1/1	3 trips per min., 40 hp.			.....	1,600
Total steam at 40 lb. per hp. equals.....							20,240

The gage pressure at the boilers is 110 lb. normal, with a 10 per cent. variation up or down. The proper way to ascertain the steam consumption of the various units is by means of an indicator. Lacking this, however, the quantity used by any of the units may be calculated as follows: Roller Screen Engine—The boiler pressure as 120 lb., a line drop of 10 lb. gives us 110 lb. gage at the engine. With ½ cutoff the mean effective pressure will be approximately 80 lb. This is calculated from the following formula: $0.9\ [k(p + 14.7) - 17]$ equals the mean effective pressure where k is 0.847 for ½ cutoff and p is the gage pressure at the engine. Then the horsepower equals

$$\frac{80 \times 1.66 \times 78.54 \times 75 \times 2 \times 0.8}{33{,}000} = 38\ hp.$$

This engine works at three-quarters of its load, giving 28.5 hp., and during three-quarters of its time. This gives 28.5 × 40, which equals 1140 lb. of steam per hour at full operating time and 855 lb. for three-quarters operating time. In the foregoing table this is considered as 860 lb. of steam per hour, which closely approximates the calculations.

While in the preceding calculations the steam consumption has been figured at 40 lb. per hp.-hr., it must be remembered that the steam consumption is often as high as 60 lb. per hp.-hr. The water rate for an exhaust-steam unit varies from 36 to 46 lb. per kw.-hr. Assuming then an average of 40 lb. of steam per kw.-hr., the total quantity of steam as shown, and not allowing for condensation losses, would give enough steam to generate 500 kw. It was found ultmately at this particular plant, that, owing to a steam consumption greater than 40 lb. per hp.-hr. of some of the units, the exhaust line and cylinder condensations were easily covered in the calculations.

In Fig. 2 will be seen the electrical load that was carried by the turbine-driven generator, with admission of live steam above the full load line. The hoist and the Holmes car lift give a fluctuating exhaust, that is, steam is admitted to the hoist for 6 sec. per trip and no steam for 14 sec. This will be taken care of by a regenerator, which carries the steam over the idle period, giving it out as required by the turbine.

Having decided that the steam available is sufficient to warrant the installation of a 500 kw. unit, we will next consider the type to employ. There are two types of

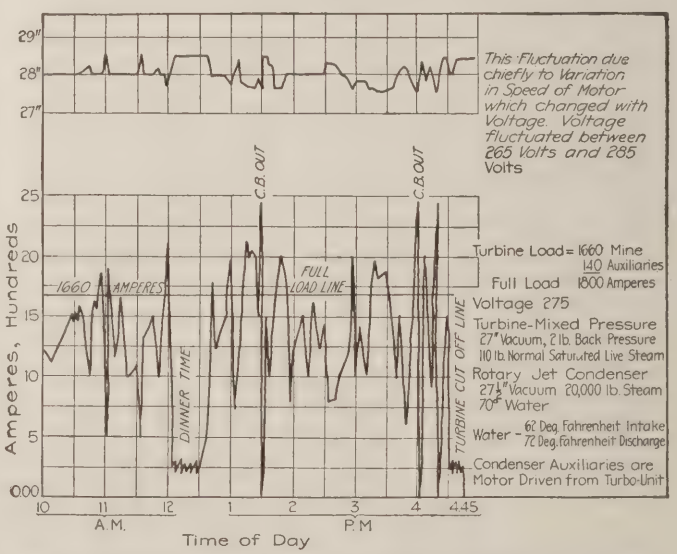

FIG. 2. ELECTRICAL LOAD ON THE PLANT AND THE VACUUM

turbines adaptable to this class of service. These are the low-pressure and the mixed-pressure machines. The first type, as the name implies, is operated entirely on low-pressure steam, and if an insufficient supply is available for operating this class of unit, under all conditions, a reducing valve has to be installed so that the live steam may be reduced from the boiler pressure to the 2 or 3 lb. pressure required by the turbine. This, of course, is

not efficient, but satisfactorily enables a low-pressure unit to be employed.

The mixed-pressure unit is equipped with two kinds of blades, one for the live steam and the other for the low-pressure steam. In some cases the blades are such that both the live- and low-pressure steam can be used on the same blading. The admission of the live steam is automatically governed, so that at a certain reduction in speed the governor opens the live-steam valve. The speed can thus be maintained with live steam when the low-pressure steam supply is insufficient to carry the load. When the load drops off, or the exhaust steam increases, the live steam is shut off automatically and the turbine operates entirely on the low-pressure steam until such time as the load exceeds that which can be carried by this supply. This is the class of turbine that is usually most suitable for mine purposes, since with the exhaust steam alone the turbine manufacturers will not guarantee the overload capacity from the turbine that the generator will carry momentarily. They will, however, do so with a mixed-pressure unit. This question, of course, is governed by local conditions.

The generator may be alternating or direct current, as required by the company's conditions, and may be connected either directly or through reduction gears. The transmission of power through modern high-speed reduction gears is quite efficient, so that this means of connection is no longer considered uneconomical. It is necessary, however, that the life of such gearing be specified and considered in the proposal from the manufacturers.

An outline of the specifications for an exhaust-steam unit suitable for coal mines, is as follows:

1. The turbine shall run smoothly and furnish the required power for full load of generator, at the rated speed, under any of the following conditions: Exhaust steam pressure, 2 to 4 lb. per square inch; vacuum, 27 to 29 in. of mercury referred to a 30-in. barometer. Overloads may be carried by live steam, automatically, at 110-lb. pressure per square inch, with a 10 per cent. variation below and above this pressure.

2. The unit shall run without undue noise, excessive wear or heating, and must be capable of running for long periods at full load.

3. The turbine to be of sufficient power when running at rated speed, to develop 1¼ times the rated full load of generator.

4. The valve gear shall work, automatically, over the total range of conditions, that is, operation from zero to 1¼ times rated load of generator, when operating under normal live-steam conditions of 110-lb. gage pressure per square inch, 3-lb. gage pressure exhaust steam, and 28-in. vacuum referred to a 30-in. barometer.

5. The turbine shall bear without injury the sudden throwing on or off of 1¼ times the rated load of generator, which may be brought about by the throwing out of the circuit breaker or other cause.

6. The speed variation shall not exceed 2½ per cent. when the load is varied between full load to 20 per cent. of full load, gradually or in one drop, the turbine operating under running conditions.

7. The speed variation shall not be more than 3½ per cent. when the load is thrown suddenly on or off under normal conditions.

8. A common sub-base shall be furnished for the proper mounting of the turbine, reduction gears (if any) and the generator, and planed projections shall be provided for leveling same.

9. The sub-base to be provided with bolt holes for foundation bolts, which bolts will be supplied by the coal company.

10. All external nuts, liable to frequent use, shall be case-hardened, and where they are liable to work loose shall be furnished with lock nuts. The seats for the bolt heads and nuts shall be faced.

11. The adjoining portions of the machine are to be given plain corresponding marks, for convenience in reassembling.

12. All necessary wrenches, lifting eyes, jacking bolts for removal of wheels, special tools, feelers, etc., are to be furnished by the turbine manufacturer.

13. Sufficient tests are to be made by the turbine manufacturer, at his own expense, to insure the proper conforming to these specifications. Two tests shall be made by the coal company at the plant after erection. Any repairs and defects developing at the first test at the plant shall be remedied before the second test and before final acceptance.

14. The live-steam inlet shall be equipped with an automatic emergency throttle valve, in such a way that it will automatically close with a 10 per cent. increase of speed above normal.

15. All flange drillings shall be standard, except the flange drilling for the live-steam connection, which shall be extra heavy drilling. Companion flanges shall be furnished where this is not done, and flanges shall be threaded for the size pipe that is called for on plans.

16. Forced lubrication is to be used on all bearings on which shaft pressure exceeds 20 lb. per square inch of projected bearing surface. In case of forced lubrication the oil is to be cooled by water in contact with coils through which oil flows. The coils and water-circulating system to have the connections outside of pedestal.

17. The upper and lower halves of main bearings shall be removable, without removal or displacement of the shaft.

18. Ball thrust bearings shall be used where necessary.

19. Provision shall be made in the construction of the complete machine so that the armature can be removed without excessive dismantling.

20. A pop safety valve exhausting to the atmosphere of a size sufficient to prevent an injurious back pressure arising in the turbine casing, due to a leaky throttle valve, shall be provided.

21. The assembled turbine is to withstand a hydrostatic test of 50 lb. per square inch, without showing undue stress or leaks.

22. Provision shall be made on all oil discharge from all bearings to observe the flow of oil from each bearing; and if bearings are also water-cooled, a similar provision for observation of cooling water flow shall be made.

23. An adjustable relief valve shall be furnished to protect the oil pump.

24. The oil tank is to be supplied with a sight gage and a ¾-in. bib-cock at lowest point to permit the withdrawal of the oil, and a cock shall also be supplied to permit the withdrawal of the cooling water.

25. Mandrels, with collars, complete, shall be furnished for renewing babbitt metal of all babbitted bearings.

26. The following gages shall be furnished: One 6-in. combination gage showing 30-in. vacuum and 30-lb. pressure; one 4-in. oil-pressure gage at oil pump; one tachometer for registering turbine speed.

27. An automatic device shall be furnished to break the vacuum in the turbine exhaust end when overspeed exceeds 10 per cent. above the normal operating speed, which device shall also control the live-steam throttle.

28. All workmanship on turbine shall be first-class, and appearance of the machine shall be as neat and as efficient looking as possible.

An outline of the specifications for the generator is given in the following:

1. Provision shall be made for vertical adjustment of magnet frame with bedplate.

2. Brush holders are to be staggered, so that wear over commutator surface may be even.

3. The shaft is to be provided with suitable means to prevent the oil from the bearings from working along the shaft to the commutator or armature.

4. Provision shall be made for the mounting of a commutator turning tool.

5. The field rheostat is to have a range of adjustment from 10 per cent. above to 20 per cent. below normal voltage.

6. The jump in voltage shall not exceed 15 per cent. when full load is suddenly thrown on or off.

7. The normal voltage to be ——— volts, compounding up from this, at rated speed, to ——— volts at full load.

8. The generator is to be able to carry a normal overload of 25 per cent. for two hours, with a temperature rise not exceeding 55 deg. C. on commutator and 50 deg C. in the windings and armature, at a room temperature of 70 deg. Fahrenheit.

9. The generator is to carry the rated full load of ——— amp., continuously, with a temperature rise not exceeding 45 deg. C. on commutator and 35 deg. C. in windings and armature, in a room temperature of 70 deg. Fahrenheit.

10. The efficiency of the generator is not to be less than as follows: ½ load, 88 per cent.; ¾ load, 90 per cent.; full load, 91 per cent. 1¼ load, 91 per cent.

11. An insulation test of 1500 volts alternating current shall be applied to all windings, and the windings shall not be punctured or broken down at this test.

12. The generator is to be compound-wound, and is to be provided with all necessary terminals for cables from switchboard.

13. Equalizer terminals shall be provided, and this generator is to parallel a generator having the following characteristics: Size, ———; voltage, ———; compounding characteristics, ———; driven by ———, etc.

(To be continued)

Increased Cost of Railroad Coal

The following table, prepared by Director General of Railroads McAdoo, strikingly illustrates the steady increase in the cost of railroad coal since 1915:

Year	Tons	Price Per Ton	Total Cost
1915	122,000,000	$1.13	$137,860,000
1916	136,000,000	1.32	179,520,000
1917	154,000,000	2.12	329,000,000
1918	166,000,000	2.95	489,700,000

Gulf States Steel Co. Byproduct Plant

In April, 1917, the Gulf States Steel Co. started to operate its byproduct plant of 37 Koppers coke ovens at Gadsden, Ala., shown in the accompanying illustration. This company owns or controls coal, iron ore and limestone properties in the vicinity of its steel mills, blast furnaces and byproduct plant. Thus ideal conditions exist for the production of low cost iron. Labor conditions also have been good, up to the time of general disturbance—a further contribution to the successful operation of the Gulf States steel plants.

The byproduct plant of the Gulf States Steel Co., shown in the illustration, is reported to have been particularly successful in operation. The most prominent features of the plant as shown are the coal handling and storage buildings. Coal is unloaded from railroad cars into a hopper from which it is conveyed to the top of the building shown at the left of the illustration. In this building the coal is crushed and pulverized, then moved by another inclined conveyor to the coal bin shown in the center of the illustration. The 37 byproduct coke ovens are directly to the right of the coal bin. The steel stack at the right of the bin furnishes draft to the coke ovens, to keep up a circulation of burning gases in the oven heating flues and hot products of combustion through the regenerators.

The byproduct plant is equipped with complete apparatus for producing ammonium sulphate, tar, benzol, etc., in addition to coke. The surplus gas from the coke ovens is used for reheating steel at the wire mills of the company. The plants for treating the byproducts —ammonia, tar, etc.—are shown in the background.

BYPRODUCT PLANT OF GULF STATES STEEL CO., GADSDEN, ALABAMA

Coal Mine Photography—I

By H. A. WILLIAMSON
Fairmont, W. Va.

SYNOPSIS—*The camera can often be used to supplement or expedite the work of the drafting room. It may also be employed to illustrate complaints or establish the reasonableness of claims. For photographing plans special plates and developers are advantageous, while for certain kinds of reproductions suitable color screens may well be employed.*

IT IS doubtful whether more than a very few mining companies make use of the photographer in connection with their work, and yet the possibilities of economies in time, material and convenience to officials and employees of all classes are large.

Probably the greatest economy and also the greatest convenience lies in the use of photographic reproductions of maps of mine workings. All agree that maps of workings on a scale of 100 or 200 ft. to the inch are large and inconvenient to handle, yet if the original tracings are made on a smaller scale the drafting-room work becomes laborious and slow and requires draftsmen of high skill in order to make the work intelligible; furthermore, the skilled draftsman commands a high salary and is hard to get at any price.

By producing the original maps on a standard scale of 100 ft. to the inch and then photographing this map down to 500 ft. to the inch a map is obtained which is entirely legible and convenient to carry in the pocket and to use in cramped quarters such as are often found in mines. They are also convenient to attach to correspondence and entail less expense in mailing. Quite crude lettering on the original map, if only it is sufficiently large to reduce, becomes reasonably good looking on reduction five times.

Camera Valuable in Drafting Room

In an office where a large amount of drafting is done (especially if parts of it be the building up of new maps from parts of others, frequently on various scales) there is no question of a camera being an economy. By reductions and enlargements parts of maps or other data can be brought to a standard scale with a rapidity and accuracy not to be obtained by even the most expensive pantograph or other mechanical method.

If an original map happens to be in various colors and the information conveyed by one or two colors only is wanted, screens can be used intensifying those tints desired and eliminating the undesirable. Old maps of great value can be photographed and from the plate enlargements or reductions can be made in any quantity, the valuable original being filed away as a matter of record.

Data from technical journals or other matter can be copied in convenient form and distributed to employees. One organization has obtained from a large public library various technical books containing information of value and copied with the camera such pages as are desired. These people have in this manner secured a library of essential information in compact form and of great value. Had it been necessary for them to purchase the books complete it would have been expensive and cumbersome, as in many cases there were large volumes of several thousand pages where they only desired possibly five or six pages of technical tables or similar data.

An item which has been of great value to one mining company has been the use of photographic enlargements of parts of the topographic sheets issued by the United States Geological Survey. These sheets contain information in regard to streams, roads, contours and other features. In establishing locations for new operations it was found that by photographing that part of the topographic sheet covering the specific area, and making an enlargement from the resulting negative, it was possible to bring the scale up to as much as 300 ft. to the inch (the original being one mile to the inch). This brought the contours to such size that it was possible to do a large part of the preliminary estimating before it became necessary to run accurate levels on the ground. As this allowed a large amount of office work to proceed ahead of the data brought in by the field parties a considerable period of time was saved.

Photographs Helped Settle a Claim

Some time ago a railroad company furnished to a certain mining company quite a number of badly damaged cars and also a number of cars containing large quantities of refuse material. The company receiving these empties complained on various occasions but could get no satisfaction; in fact were rather abruptly treated. This organization called in a photographer who made pictures of some 15 or 20 damaged and refuse-filled cars. These pictures were forwarded to the railroad company with a brief letter calling their attention to this evidence, which did not admit of refutation. The result was prompt and satisfactory, and this particular company has had no similar trouble since.

It is not to be supposed, however, that it is essential to have a photographic department in order to do this work. While this is desirable it is not absolutely necessary. The local photographer with a little coaching can do this work and usually welcomes it as an addition to his income.

As in everything, if success is to be obtained there are certain features which should be observed. While it is entirely practical to photograph almost anything, naturally better results are obtained if the possibility of photographing the final work is kept in mind at the time of producing a map.

To make a map excellent for photographing does not require any special effort, nor does it spoil the map for any other purpose. If one will bear in mind that a sharp clean line photographs better than a fuzzy one, the line need not be broad. It should, however, be dense; that is, a black line, good for photographing,

when held up against the light is sharply black and not gray in places where the ink has not been laid on from a well-filled pen.

As to lettering, it has been found after several years' trial that on a map to be reduced five times no letters on the original should be less than $\frac{1}{10}$ in. high, and they should be sharp and clean-cut. They do not have to be particularly well done, although, of course, the better the work the better the final map will look. A letter even as much as $\frac{1}{2}$-in. high poorly done does not look so bad when it is reduced five times or more. To repeat, with two simple rules: Make your line black, not gray. A $\frac{1}{10}$-in. letter will stand a five times reduction.

There is no reason why any ordinary draftsman, together with an intelligent photographer, cannot turn out a good photographic map.

For copying maps, either on tracing cloth, paper or mounted map paper, if no ink except black is used (or in some cases black, red and orange), the photographer should use a sensitive plate commonly termed a "commercial" or "contrast" plate; and in developing he should use a "contrast" developer, the object being to get a sharply black and transparent negative. It is of course necessary either to carry a stock of these "contrast" plates or to order them for each job. As they are cheaper than the usual portrait plates and also keep much better in storage than other grades, it is not much expense to carry a few of them in stock. (If kept dry and away from extreme heat these plates may be stored for 12 to 18 months without deterioration, and in some cases have been used with success after 24 months' storage.)

A Good Development Formula

A good developer for this work is made up as follows: Water, 15 oz.; sodium carbonate, $\frac{1}{2}$ oz.;[1] sodium sulphite, 1 oz.; potassium bromide, 15 gr. Of this take sufficient to cover the plate well and add three grains of dry pyrogallic acid for each ounce. (Pyrogallic acid should be added just when you are ready to use the solution.) The temperature should be 70 deg. F. Density comes slowly—the plate should be fully developed in three to five minutes. When developed immerse the plate in 16 oz. of water and 30 gr. of citric acid. After this fix thoroughly in an acid fixing bath.

If the map to be reproduced is in colors, a color sensitive, or as they are commercially known a "panchromatic" or "trichromatic" plate should be used with the developer recommended by the manufacturer of the plate. If the map is badly soiled or yellowed with age a screen of light yellow may be used to increase the contrast and cut out the dirt.

In field work (such as the railroad complaints mentioned above) pictures for advertising showing various grades of screened coal, character of equipment, working places or machinery within the mines, there is a wide range for the photographer. To do such work properly requires some simple equipment, which almost every photographer has, and quite a good deal of ingenuity. Topographic and triangulation work can be largely supplemented and aided by camera work. This, however, requires greater skill and special equipment, and would mean the employment of a photographer specially fitted to do the work; such expense would hardly be justified except in the case of large and important areas where a great deal of detail information was essential to carry out some special plan.

There is also the wide field of the motion picture camera, particularly valuable in advertising, and in safety and welfare work. This, however, is an industry within itself and should be dealt with apart from other camera work. The initial expense is high, as is also the operation, and such work is not ordinarily justified by the results except in special cases.

Naturally photographic work along the lines indicated can be abused and made expensive, but this is hardly likely to occur as such features are easily recognized and corrected. As a whole there is almost no limit to the work that can be carried on with the camera. There are economies that can be accomplished in no other manner, and as a convenience, once thoroughly tried out, it is seldom if ever abandoned.

(To be continued)

[1]Note: If desiccated sulphite and carbonate are used, use 100 grains carbonate instead of $\frac{1}{2}$ oz. and 220 grains sulphite instead of 1 oz. All the foregoing figures are based on 437½ grains to the ounce.

Briquets from Anthracite Slush

Anthracite producers are now giving earnest attention to the matter of increasing the fuel supply through salvage of coal fragments which have been slushed away from the breakers and lost. It has been found possible to utilize such waste anthracite by manufacturing it into briquets which make perfectly good and effective fuel. On a small scale this has been done with success and to the satisfaction of those who have used briquets.

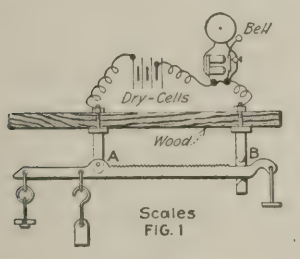
Now the thought is to develop the briquet as a by-product of the anthracite industry. In 1917 the Lehigh Coal and Navigation Co. produced 30,001 tons of briquets. These consisted of coal fragments the size of pin heads and less, bound together with tar and compressed into solid lumps by high pressure. Briquets burn to excellent advantage in furnaces, ranges and open grate fires. As made they average about the size of nut coal.

Much of the anthracite refuse which is now swept down the streams and rivers of Pennsylvania is carbon, but until recently there was no way to conserve such lost coal to economic advantage. In the development of the anthracite industry and the progress made in all directions it has been found possible to salvage more and more coal which formerly was wasted.

Improved mining appliances and methods enable proportionally more of the anthracite in the ground to be taken out than in the old days. This is a gain in conservation of a valuable natural resource.

Under the old methods and before the breakers were highly perfected as they now are, a great deal of anthracite was, of necessity, discarded. Hence the huge culm banks of the past, which are now being washed over through washeries, yielding a large amount of coal in every way as good as fresh mined anthracite.

Salvage of the coal now lost in the slush washed away from the breakers will be, as it were, the last word in getting and making of commercial use all that is taken from the anthracite mines that will burn.



Electric Signals on a Modern Tipple

By FRANK HUSKINSON
Lafayette, Colo.

SYNOPSIS—*A system of signals is here described that enables intercommunication between various localities on the tipple. The scale signal is semi-automatic in that when a car has received a certain loading a warning bell is sounded.*

ON A tipple that has two dumps and where coal comes from several mines, a reliable system of signals that can be heard above the noise is necessary to enable the dumpers to know when to start or stop the dumping of coal. Nowadays, when the railroads require that all cars must be loaded to within a very small per cent. either under or over their rated capacity, it is necessary where there are several scales that these be arranged in such a manner as to give a warning signal when the car is about loaded. It is also necesary that the weighmaster be enabled, by a system of signals, to let the dumpers on top of the tipple know when to stop and when to start to dump coal, while he furthermore must be able to signal to the box-car loader operator and the car droppers, and they to him.

The tipple at the mines at Delagua, Colo., have two dumps, each one independent of the other. The average amount of coal handled over this tipple exceeds 2200 tons per day. There is a weigh-house for each dump on each side of the tipple to weigh the coal as it comes out of the mines. Most of the coal is loaded into box-cars. There are four railroad tracks underneath the tipple, each with its separate scale. The slack is

FIG.4

FIGS. 1, 3, 4 AND 5. SHOWING VARIOUS DETAILS OF SIGNAL SYSTEM

screened out and the balance of the coal is loaded into coal cars or box-cars.

The scales for weighing the railroad cars are located together in a room halfway from the bottom of the tipple to the top. One man attends to all of the weighing and billing out of all the railroad cars, and it is seldom that a car is overloaded or underloaded, due mainly to the system of electric signals.

In the weighmaster's room each scale is arranged with a signal system, as shown in Fig. 1. The scale beam is pivoted at *A*, and connection is also made here. The stop at *B* is normally open on the upper side until

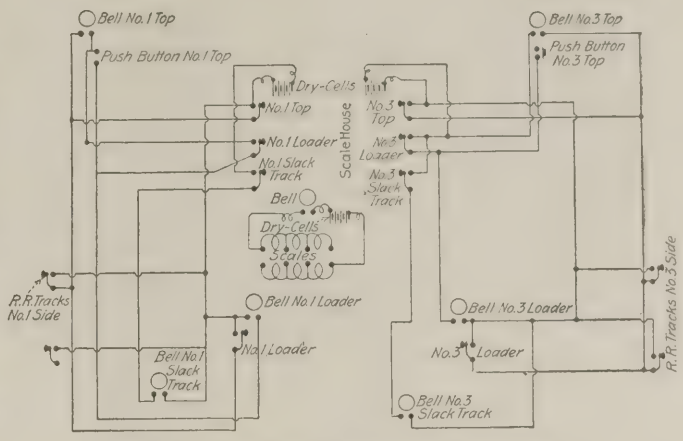

FIG. 2. COMPLETE WIRING DIAGRAM

the scale beam balances. The bottom stop on *B* is insulated from the beam by a piece of fiber. When the scale beam balances it makes contact with *B*, to which another connection has been made, This closes the circuit, causing the electric bell to ring as long as the scale beam is touching *B*. It thereby attracts the weighmaster's attention to the scale. As soon as a car is run onto the scales the weighmaster weighs it and sets the scale so that it will balance at a few hundred pounds less than the capacity of the car. He pays further attention to the scale only when the bell rings.

In order to let the box-car loader operators know when to start or when to stop loading there is a strap key at each scale that rings a bell at the box-car loader. A strap key is also installed at each scale so that the weighmaster can ring the bell at the top of the tipple to let the dumpers know when to stop or when to start dumping coal. Furthermore, the bell box at the top of the tipple is fitted with a special push button, so as to ring the bell at the box-car loader, and the box-car loader is provided with a strap key for ringing the bell on top of the tipple. Two strap keys are located at each railroad track. These keys are placed so that a man can signal with one of them from the ground or from the top of a box-car or coal car, to start or stop the dumping.

In Fig. 2 is shown the complete wiring diagram for the entire system of bells and strap keys. In Fig. 3 is shown the construction of one of the strap keys. These are easily and cheaply made and are reliable and durable, with nothing to get out of order. In Fig. 4 is shown the construction of a combination bell box and special plunger type of switch, all completely inclosed in a weatherproof box, so that the weather as well as those persons that are always experimenting and putting such things out of order can not get to it. This

switch is reliable and durable, and will not get out of order.

I made up and installed the complete system as shown in the diagrams, over a year ago, and it has not given any trouble other than the dry cells having to be replaced periodically. At the present time I am figuring on taking out the dry cells and putting in a good bell-ringing transformer. A diagram of the transformer is shown in Fig. 5. This can be used instead of the dry cells. The change will mean that the bells, if made for direct current, will have to be readjusted and will require more voltage from the bell-ringing transformer than they do on the dry cells. As shown in Fig. 2 the scheme of wiring is interesting since it is designed to give the most satisfactory service with a minimum amount of wire.

Coal Washery Collapses

By Correspondent

The photograph shown below is of the wrecked washery at the Parrish colliery of the Lehigh & Wilkes-Barre Coal Co., Plymouth, Penn. The washery was working as usual during the morning, but as the afternoon operations were resumed it was noticed that the wooden foundations were cracking and, therefore, the employees were ordered out. The building fell to the ground at 1 o'clock, Apr. 29, 1918.

The washery at this operation was built in 1910 and enlarged in 1912. The trouble began in the center of the building, directly under the pockets, which rested on upright pieces 12 x 12 in. in size. As soon as the supports under the pockets gave way the building collapsed toward the center from the four sides.

The building site is located on low ground, and the occasional floods and the wash water resulting from the operations rotted the foundations, thus weakening the supporting timbers, the decay of which was of course accelerated by the alternating wet and dry condition. Owing to the warning, no one was hurt.

Some Observations on Ice, Water and Steam

By W. D. Owens
West Pittston, Penn.

Ice is found to be much lighter than water. In other words, it requires 109 cu.ft. of ice at a temperature of 32 deg. F. to produce 100 cu.ft. of water at the same temperature. This is the reason why ice floats, having about one-eleventh of its bulk exposed above the level of the water. Ice, also, to a certain extent, at a temperature of 32 deg. F., has the power of absorbing heat without any apparent rise in its temperature even though a change of state takes place. Thus, if you take a pound of ice at 32 deg. F., and another pound of water at a temperature of 174 deg. F., and insert the ice into the water at the above temperature, the heat of the water will convert the ice into liquid. There will then be 2 lb. of water, but its temperature will be only 32 deg. F. Thus, 142 units of heat were absorbed by the 1 lb. of ice, the only effect being to convert it into water. Hence 142 B.t.u. is called the latent heat of ice.

In converting the pound of ice into water it contracted in bulk about 9 per cent.; but if heat is applied further to the 2 lb. of water at 32 deg. F., the volume will still continue to contract or diminish in bulk until the temperature reaches 39.2 deg. F. At this point water weighs more per cubic foot than at any other temperature. In other words, if water is made either higher or lower in temperature than 39.2 deg. it will expand.

Water when heated under atmospheric pressure from 39.2 to 212 deg. gradually but continuously expands. At the latter temperature, however, it ceases to increase in volume; but upon continued absorption of heat is converted into steam. It also ceases to become warmer, or higher, in temperature as long as the pressure of the atmosphere is constant.

The amount of expansion between 39.2 and 212 deg. is but 4.3 per cent., and its specific gravity undergoes a corresponding change. Pure rain water weighs 62.424 lb. per cubic foot at 39.2 deg. F., and its specific gravity

WRECKED WASHERY AT THE PARRISH COLLIERY OF THE LEHIGH & WILKES-BARRE COAL CO.

WATER-PURIFYING PLANT AT COAL MINE IN CLEARFIELD COUNTY, PENNSYLVANIA

at this temperature is taken as a standard, being here unity or one. All comparisons between the weight of air and water should be taken at a temperature of 39.2 deg. F. or 4 deg. C. The weights of the two fluids at this temperature are in the ratio of 1 to 786, or, in other words, water is 786 times denser than air at this temperature. If air and water are heated above this temperature the expansions are not proportional. Water expands on an average between 39.2 and 212 deg. F., about 1 in 4000, but the expansion of air is constant—1 in 460. If, however, the temperature of both air and water be reduced below 39.2 deg. the air will contract 1 in 460 and becomes heavier per unit volume, while water expands and becomes lighter.

If 1 cu.ft. of water is raised in temperature to 212 deg. F., or boiling point in the atmosphere, and kept boiling continuously, it will in a certain period be all converted into steam the volume of which will be equal to 1696 cu.ft. This steam will however retain a temperature of 212 deg. F. or 100 deg. C.

Again, if this body of steam, 1696 cu. ft., is now allowed to enter a volume of water at 32 deg. F. and weighing 5.36 times as much as the steam, the steam will all condense into water; but the temperature of the whole body will be found to be 212 deg. F. In other words, 1 lb. of steam at 212 deg. F. will raise 5.36 lb. of water from 32 deg. F. to a temperature of 212 deg. F., when the whole resulting 6.36 lb. will show this same temperature. Therefore $(212 - 32) \times 5.36 = 966$ B.t.u., which is called the latent heat of steam. This is equivalent to 536 units of the centigrade thermometer.

The molecular weight of water vapor is 8.96 when hydrogen is taken as 1; oxygen, 15.96; common air, 14.45, and nitrogen 14.1; hence if a cubic foot of air at 39.2 deg. F. weighs 0.0794 lb., a cubic foot of water vapor at the same temperature and pressure will weigh only 0.0493 lb.; and, according to the rules of expansion, will weigh at a temperature of 212 deg. as follows: $\frac{460 + 39.2}{460 + 212} \times 0.0493 = 0.0366$ lb. Or dividing 62.424 (the weight of 1 cu.ft. of water at 39.2 deg.) by 1696 (its total expansion into steam), will give practically the same result; thus, $\frac{62.424}{1696} = 0.0368$ lb.

Mine Water-Purifying System

The illustration above is of a water-purifying plant at one of the large mines in Clearfield County, Pennsylvania. At some periods of the year this colliery can procure clean water from the Buffalo, Rochester & Pittsburgh R.R. for use in its boilers, but for the most part it is forced to use mine water. This water is full of impurities, and to prevent it from ruining the boilers it is treated with soda and lime, the quantity used depending on the analysis of the water.

The water tanks, of which there are three, are 15 ft. in diameter and 15 ft. deep and contain 19,880 gal. of water each. Twelve tankfuls of water are used by the boiler plant in 24 hours. After the lime and soda have settled, the water is drained off from the bottom of each tank and filtered through charcoal and sand to the supply tank. This equipment was furnished by Scaife & Son.

Referring to the illustration, the house farthest up the hill is the supply house. The one just below it is the mixing house. Immediately to the rear are the three treatment tanks. The tank shown on the extreme right is one of the two supply tanks, the water from which is fed direct to the boilers.

The ratio of the volatile carbon to available hydrogen is only one of probably several factors which may indicate the burning qualities of volatile combustible. Among the other factors the oxygen content in "moisture and ash free" coal suggests itself as the most important one.—*Bureau of Mines Bulletin No. 135.*

War as a Supreme Test of Efficiency*

By EDWARD N. HURLEY
Chairman, United States Shipping Board

IN PAST wars victory was thought largely a matter of purely military strategy. Under our highly organized system of today, the whole weight of the nation must back up with its full resources military and naval action. Otherwise there can be no effective action. This means that everything of basic importance needed to carry on the war must be operated as a unit. Coal is a fundamental. Transportation for the carrying of coal and all other commodities is another fundamental. Our Government is fast going ahead with its process of coördinating railroad systems and inland waterways, lake, coastwise and ocean transportation. Railway equipment is being provided. Fleets of ships and vessels have already been speeded from our shipyards, and many more will follow.

Whatever the length of the war, we are preparing in good measure for present and future. We are doing it in a large way worthy of our great country. Not only for the war, but for the times after the war, when we shall be called upon to do the immense work of rehabilitating devastated Europe. Other countries needed our coal before the war—nearly 21,000,000 tons of it annually. They have needed more of it since the war began. They will need it after the war. And we will not only have the vessels and other vehicles to carry on our inland and coast waters and on our railroads the millions of tons of coal used yearly in this country, but we shall have a great merchant marine of our own to carry coal and all other American products to other countries.

Up to Operators to Produce Coal

The distribution of coal is only one part of the problem. The coal requirements for the United States for the coming year are nearly three quarters of a billion tons, and if this nation is to run on a war basis during the next twelve months, the coal mines must produce at least seven hundred million tons of coal. That is an enormous tonnage that the nation calls on you to furnish. We understand that in the past your production has been limited by insufficient transportation. The fact is now well understood, but the railroads of the United States have been brought under the direct control of the Government. We are told that one billion dollars will be expended this year in improving and expanding our railroad transportation facilities. With new locomotives and cars and with new tracks, bigger yards and better terminals and with centralized control, sooner or later the mines will be furnished all the transportation needed to haul their output to the points of consumption. It will then be squarely up to you to produce the coal. In the meantime you will have suffered a progressive loss in the numbers of your employees and unless you have made preparation to get the utmost efficiency out of your mines and your organizations, we will fall far below the coal production that we will need.

It seems to me that one of the most important things your association can do is to begin active preparations now to increase your efficiency so as to maintain the production of coal at the highest possible level. You have taken the first step in this direction by working out a uniform system of cost accounting and by organizing a cost accounting department to assist mine operators to put their business on a sound basis. In every trade association the strong must help the weak and in most cases the weak are those who know the least about their own business. Accordingly, the first move to strengthen your industry is to teach those weak producers the facts about their own conditions. Coal should be mined at a profit, but no man can know whether he is really making a profit or not unless he knows his costs.

Thoroughgoing Cost Accounting Means Efficiency

Profits are not all, however. No man can know whether his organization is really efficient or not unless he knows his costs and unless he has some standard of costs, either the average for his field or the figures of the lowest producer which he can use to compare with his own. It is vital to us all to develop the highest industrial efficiency of which we are capable today. In one sense, this whole war is a test of industrial efficiency. Thoroughgoing cost accounting is the very basis of efficiency in your business, as in every other business. Accordingly, it is especially gratifying for me to know that you have already begun this first great educational work which you must carry on among the coal producers of the United States in order to increase your efficiency.

In the next place, you should examine critically your own management. In my judgment, 50 per cent. of the inefficiencies of coal production today are due to poor management. At this meeting your association should recommend that in each district a committee on efficiency be appointed and that they put forth every effort to improve the management of the mines in that district. Many of your properties are well equipped and well managed and might serve as models for all the world. They set a splendid standard for the efficiency committee to measure up to, yet you know that there are hundreds of mines that are not well equipped; that are indifferently operated; that are loading poor coal; in short, that are poorly managed. They constitute a fertile field for your efficiency committee to cultivate. This is one way for you to show the Government and the people that your association is really worth while. As long as you have inefficient management in any considerable part of the coal-mining industry, this organization is necessary for the success of the coal-mining business.

I have always thought that the mining of coal could be improved by the use of more supervision. The general manager of a certain property once told me that in his mine he had a foreman to approximately every 200 men. The president of his company, after looking into the matter, asked him to increase the

*Abstract of speech delivered before the National Coal Association at the Bellevue Stratford Hotel, Philadelphia, May 28, 1918.

number of foremen and assistant foremen to one to every 40 or 50 men. This was done, and he found that the greater attention to detail, the better care of the property, the decrease in accidents and the general improvement of his organization, resulted in a very definite increase in the production. We found the same fault in many of our shipyards when we had their management looked into. We found many yards had no competent foremen, no layout men, no supervision at all that modern industrial practice demands. We put a sufficient number of good superintendents and foremen into those yards and obtained surprising increases in the efficiency of production. Isn't it worth your while to make this kind of study of your own organizations? When we found that we did not have sufficient foremen or layout men and that many of the men did not know the best methods of work, we established schools to teach the fundamentals of shipbuilding to the men and the superintendents.

When Mr. Schwab made his first trip to Hog Island he wanted to get in contact with the workmen, the foremen, and the superintendents, instead of the president and vice presidents, and he said: "Hurley, if we are going to build these ships, I must meet the workmen, foremen and the superintendents; they are the men that are going to finish this job for us." Your superintendents and foremen are running your mines while you are here in Philadelphia. You know that the superintendent out at the mine is on the job today and that everything will go all right as long as he is there. In addition to paying good wages to your workmen, pay your foremen and superintendents good salaries and encourage them with a bonus on your increased output.

If each industry in this country would have its superintendents and foremen get together, either through some auxiliary to their trade associations or through some school, to discuss ways and means to improve their methods of production and management, they would materially benefit their industry.

Labor Playing a Great Part

Labor is playing a greater part in this war than in any other conflict which the world has known, and let me say here that in the United States labor as a whole is measuring up to its responsibility splendidly. The leaders of organized labor in Washington are men of the highest character, patriotism and honesty. All of us who are acquainted with Mr. Gompers' work know that he has endeared himself to the people of America and all of the allied nations by the position which he has taken in this war. He has about him other able men who are equally loyal and patriotic.

On the whole, however, labor as well as capital is not producing that degree of efficiency that it should produce in these trying times. If faulty management is responsible for 50 per cent. of the inefficiencies in the production of coal today, inefficiency on the part of labor is responsible for the other 50 per cent.

The reports to the Government show that from 10 to 20 per cent. of the men in the mines are not working as they should. In mines that are given sufficient car supply there are some employees who are not working as steadily as they should. Some of these men fail to work their full eight hours when they do enter the mines. Others work only three or four days a week when they might work six. Under these conditions, it is not a question at present of increasing the number of hours the mine operates per day, but it is a question of the men working fuller time each day and working more days in the week.

Men Were Willing to Work Overtime

You may say that this is primarily a matter for labor itself to deal with. In part that is true, but have you yourselves done all you can to remedy this condition? The president of one big western Pennsylvania coal-mining company recently found that with a full run of cars, a certain number of the cars were standing over at his mines every night and were not being loaded. He took the matter up with his men in a meeting and explained to them something of the necessity to the nation at present of having increased coal production to carry on the war, and brought home to them as best he could their responsibility to mine the coal. After the meeting was over, some of the English-speaking miners came to him and said that if the country needed the coal they were willing to stay overtime and get other men to help load the cars that were left over each evening. That incident serves as an illustration of the spirit that can be roused in your men if they are properly approached. They are just as patriotic as you or I. Their sons and brothers are going into the trenches.

They will do their part as earnestly as any of us if they understand clearly what their duty is, but it is first up to you, the presidents and owners of coal properties, to do your part by going to the mines personally, obtain first-hand information and explain to your men the great need for increased production.

With full running time, the mine wage scales are remunerative and the men can make good earnings. Wages are based on the effort of the individual miner. Practically all of the coal in the United States is paid for on the piece-work basis at some rate per ton. Under these conditions, if the miner wishes to increase his earnings, he can do so by working more energetically and nearer full time. In getting increased efficiency from labor, therefore, there is no question of a fair day's pay for a fair day's work. The man can get his fair day's pay if he is willing to work.

I wish to express my admiration for the United Mine Workers of America as a great labor organization that recognizes the piece-work basis.

The United States Shipping Board Emergency Fleet Corporation has established a rule that any piece-work rate set by any shipbuilder must stay in force during the period of the war. The controversies between employers and employees over the question of piecework has been most serious, and the employers in many cases have been chiefly to blame. Any manufacturer, whether he be a producer of coal or any other commodity, who sets a piece-work rate, finds he has made a mistake, and then reduces that rate, is doing a great injustice to the workman. A piece-work rate set by a manager, superintendent or foreman is a contract that should be kept in force for at least one year. Furthermore, if this piece-work rate is on a particular machine, and

the man or the operator should leave or be dismissed, the man who succeeds him should receive the same rate. A law passed by the Government making it compulsory for a piece-work rate to remain in force for a given time from the date it is put into effect would be helpful to labor and industry.

It cannot be doubted that in many industries there will be a decided shortage of labor after the war, not only in this country, but in most of the countries of the world. That country will best succeed which protects its workmen by improving their living conditions, by providing for insurance against accidents and protection for their families, and guaranteeing a fair return from their labor—all under conditions that will be helpful to make the worker a better citizen. The country taking those measures will be the country that will develop and produce the products most economically, and will be performing a world service by producing goods at a price that will be fair to other nations. Unless we have efficient management and efficient employees, our country will be at a great disadvantage compared to countries which establish these improved conditions.

It is true that labor itself must do its full share in obtaining increased efficiency from mine labor, and if the operators have committees in each district to increase the efficiency of mine operation the United Mine Workers should appoint committees to take up this matter of fuller working time and better effort on the part of mine labor. In some effective manner mine operators and mine workmen should coöperate in democratic fashion in the common cause of winning this supreme struggle for democracy by obtaining increased production of coal.

Shipbuilding Industry Solved Its Problems

Some of the problems that you are meeting in this industry we have had to meet in the building of ships, and a brief outline of our efforts to overcome them may afford you some suggestions that will be of value in solving your own problems.

In the sphere of shipbuilding we built 91 new wood and steel yards since last July. Most of the organizations that built these yards and many of those working on our great new merchant marine are men who had never before built ships. A vast force of men were put to work on yards and ships of all kinds. New foremen and new superintendents were engaged. Many obstacles, such as develop in a new industry, turned up, but we constantly tried to improve our knowledge about the building of ships. One particularly serious problem faced us. We found we did not have sufficient foremen or layout men. We started a number of schools to educate the men and teach the fundamentals of shipbuilding. Less than a year ago there were not 45,000 men employed in American shipyards—today we have 300,000 skilled mechanics and laborers in our shipyards, and 250,000 additional men are employed in making boilers, engines, winches, etc.

We have a Department of Education and Training, whose task it is to train workmen, foremen and superintendents. The training of the various kinds of shipbuilders in the yards is accomplished by putting the men to work on production jobs, under the supervision of a yard instructor. This yard instructor has full charge of gangs while they are learning. The jobs they do are selected for their educational sequence, but are all of them production jobs. The efficiency of a green gang under training will average about 80 per cent. that of a finished workman. Yard instructors are skilled mechanics to whom has been given a knowledge of teaching method. This knowledge is gained in a training center, which is designed to teach the skilled mechanics how to instruct. The mechanic is given an idea of instructional management, and how to get the instructions across effectively. The difference between a yard instructor so trained and a production foreman is that the former knows how to go about the job of teaching, whereas the latter does not.

The first training center was established at Newport News. To it were sent skilled mechanics, selected from the yards. They were given a six weeks' course of training, eight hours a day. During the last part of this course they were obliged to spend 40 hours in the actual handling of gangs of green men. Yard instructors are drawn from a variety of trades, such as riveters, ship fitters, ship carpenters, caulkers, etc. While each one teaches a different line, the instructor training which they get is essentially the same. Twenty-two plants have sent men for training as yard instructors. Of these 216 have completed their training and 74 are now in training.

Could Make Improvement in Other Industries

In addition to the training of green men, there exists the problem of taking men who are already skilled in allied trades, but have never worked in shipyards, and making them into shipbuilders. This is called a trade conversion course and consists essentially of determining what supplementary work a skilled mechanic from the allied trades must have in order to give him the necessary knowledge to do shipbuilding work. Careful studies of this conversion process and the instruction necessary have been made and special trade conversion instructors are employed in a number of plants to meet this situation.

If we could do this in the shipbuilding industry, if we could develop in a year the building of wooden ships which has been a long-lost art, if our workmen in many yards have increased in efficiency more than 25 per cent. through this method in the past few months, it can be done in other industries. We did it by improving the management. Where we have efficient management we have efficient workers. You can't expect to have efficient workmen in an inefficiently managed shipyard nor can you expect good results.

It we have thus been able to start anew the building of ships and in a year's time have organized a great new industry employing almost as many men as yours, if we are throwing away the old standards and setting up new ones, if we are breaking records every day, if we are devising new methods to improve our management and increase the effectiveness in the shipyards, I trust that you men will rouse yourselves to new efforts, will take a fresh view of your industry, and will obtain a sufficient production of coal, in spite of all the difficulties that may beset you, and will give the Government your thoroughgoing support in carrying on the war. These are the results that the nation will inevitably expect from you and I am sure you will not disappoint the American people.

We are building ships not alone for the war, but for the future of world trade. Remember that once their part in the winning of the war is ended, a large number of them will be engaged in bringing back to home and industry the victorious soldiers, and in transporting to Europe the materials necessary for reconstruction of normal life freed from the menace of avaricious autocracy. These vessels will serve the commerce of other nations equally with our own.

The building of ships, the mining and distribution of coal, the production and conservation of food products and other important war necessities are all vital to the nation's needs during these trying times. No great task can be undertaken, if quick action is to be obtained, without the making of some mistakes. We may make mistakes, but we are moving forward and getting results. We cannot go far wrong with the American people united and working for victory. If each of you will do your part, putting your country above everything else, we will win.

Anthracite Distribution Program for Current Coal Year

The Anthracite Committee of the United States Fuel Administration—composed of Joseph B. Dickson, S. D. Warriner and W. J. Richards—has gone over the whole problem of fuel supply and distribution in conference with Dr. Garfield. Those in charge of the bituminous distribution, who have an equally difficult problem, have also been consulted. Both must be worked out together to best uphold the public interest. To meet the war needs compels use of considerable anthracite in place of bituminous. This has been arranged through undertakings to substitute bituminous wherever it can be used.

Upon such basis of coöperation, which entails not only readjustments in the country's fuel supply as between sections and uses, but a new balance as between anthracite and bituminous, domestic sizes of anthracite will be distributed during the coal year, which runs until Apr. 1 next. This distribution and arrangement has the approval of Dr. Garfield, United States Fuel Administrator. The following allotments will be made under it:

1. It is closely figured that a total of 54,345,783 tons of anthracite of domestic sizes will be available for distribution to consumers during the period. Such amount will be an increase of 2,668,323 tons, or more than 5 per cent., over the actual distribution for the coal year 1916-1917.

2. Distribution to New England and Atlantic states will be materially increased to meet the greater requirements of their expanded population. It is to be noted that the greater needs in these states for domestic fuel are not in full proportion to the larger population, for the reason that the average number of people per house, particularly among industrial workers, has increased so that the additional houses to be warmed are not as many as might be expected.

3. Government requisitions for anthracite to be supplied the army and navy, and to war industries and utilities which require it, will be fully met.

4. To make possible such necessary increased distribution upon Government orders and through those sections of the country where the people are dependent upon anthracite for heating and cooking, there is no alternative but to curtail shipments to other states and to bar anthracite entirely from many more where it has been used but in which bituminous and other fuels can be procured and substituted.

Comparing with the coal year 1916-17 the foregoing work out as follows:

	Tons
Increased production	2,668,323
Curtailment in distribution	2,202,288
Gain from barred sections	765,931
Total gained	5,636,542
Less army and navy	600,000
New balance available	5,036,542

Such available freed balance is allotted to increase the distribution of domestic anthracite among the New England and Atlantic states. It enables an increase of 1,497,621 tons, or 17 per cent., in the total amount to go to New England, and of 3,538,921 tons, or 13 per cent., in the amount for the Atlantic states.

Fuel Administrators of the six New England states figured the probable demand of 10,699,400 tons for domestic requirements. The allotment made by the Anthracite Committee is 10,331,000 tons of domestic sizes for all purposes.

Fuel Administrators of the Atlantic states—New York, New Jersey, Pennsylvania, Delaware, Maryland, Virginia and the District of Columbia—asked for a total of 33,413,621 tons for domestic requirements. To the Atlantic states the allotments by the Committee total 31,417,154 tons of domestic sizes for all purposes, an increase of 12.69 per cent. over last year.

Increased Allotment for New England

Increased allotments to New England and the Atlantic states are made with regard to their necessities—the larger population which the war has concentrated in such sections, their essential dependence upon anthracite, and the virtual impossibility of getting bituminous for their needs. Shipments to the full amounts of the allotments are dependent upon the expected output of domestic sizes being reached.

It must be understood that these allotments to New England and the Atlantic states represent absolutely the maximum amounts which can be given without grave injustice to people elsewhere in the United States and Canada who require anthracite in substantial amounts.

The Anthracite Committee states further that should it be possible to gain any anthracite out of the nearly 2,500,000 tons used by the railroads for fuel, or to expand the total production above the 54,345,783 tons of domestic coal estimated as the output for the year, such gained coal will be distributed to increase the allotments as now fixed for the central and northwest states, which, as it stands, are called upon to make large sacrifice from their accustomed prewar supply of anthracite.

Compared with the actual distribution for the coal year 1916-17, both by state and groups of states, the allotment of domestic anthracite for all purposes for the current coal year as made and now publicly announced by the Anthracite Committee is as follows:

ALLOTMENT OF DOMESTIC ANTHRACITE FOR ALL PURPOSES FOR THE CURRENT COAL YEAR COMPARED WITH COAL YEAR 1916–1917

	1916–1917 Distribution	Allotment, 1918–1919	Increase, Per Cent.	Decrease, Per Cent.

When Mine Accidents Occur

Speaking before the American Institute of Mining Engineers at its recent meeting E. E. Bach, the sociological director of the Ellsworth Collieries Co., declared that at least 75 per cent. of all accidents can be prevented and that the Ellsworth concern reduced its accident list 40 per cent. in the past year.

It is in the months of July and August that the greatest number of accidents occur. October and February have the fewest of the unfortunate occurrences. The investigation of the Ellsworth Collieries Co. as to the relative hazards of the days of the week has covered a period of 7 years and shows that the greatest number of accidents occur on Tuesday and the second largest list occurs on Monday. Apparently these are the results of celebrations held on previous Saturday nights and Sundays. There are 52 distinct holidays scattered through the year, aside from the regulation American holidays, and they are followed by a lot of accidents.

The greatest number of accidents occur in the morning between 10 and 11 o'clock. In the afternoon they occur between 2 and 3 o'clock. T. T. Read, of the New Jersey Zinc Co., said that August was the unfortunate month for accidents at the zinc company's mines and that 10 o'clock in the morning and 2 in the afternoon, as Mr. Bach has found, had an unfortunate preëminence in accident rates.

Minecdotes

The Mine Foreman Solves a Hoisting Problem

An irascible mine foreman of Welsh descent, after completing his day's work, went to the foot of the hoisting shaft to be hoisted to the surface. When he arrived at the shaft foot ten men were on the cage and the bottom man was about to give the bell. "Hold on there," said the foreman, "I am going up along."

"There are already ten men on," responded the cager.

"Never mind," said the foreman, "don't you think I know what I am doing? The last man who got on that cage get off."

No one moved.

"I tell you, the last man get off."

Still no one made a move to get off.

"All right, then," he said. "I'll fix you. Come off of there, every man of you."

Of course, the men as ordered filed off the cage. The foreman, after getting on, said, "Now, then, nine of you get back on."

In Which the Paymaster Settles a Complaint

Jim was a hard-working miner and usually lifted a fat envelope on pay day. But Jim had a great fondness for the dollar, and it seemed as if he never got quite enough in his envelope to satisfy his craving. So he fell into the habit of complaining whenever he received his statement.

He would walk to the pay window, look at his statement, and then blurt out with an indignant snort, "Say, mister, I am short about five."

The paymaster would talk to him, explain every detail of his account, and when all else failed the mine boss and superintendent would be called in to help smooth matters. In the end Jim left the pay window breathing dire maledictions against corporations large and small and all paymasters in general.

The paymaster stood this for several months. Finally the thing got on his nerves, and he thought of a little scheme to put an end to it. His idea was to put five dollars more in Jim's envelope than was really due him, and await events.

Pay day arrived, so did Jim. He walked up to the pay window, went through the same maneuvers, finishing as usual with, "Say, mister, I'm short again."

The paymaster took the envelope back and carefully counted the money. Then, producing the accounts, he proved that the envelope contained five dollars too much and said, "I'm sorry, but I must take this five out of your envelope."

Jim looked quite crestfallen as he handed back the extra five; but the scheme worked like magic, for he never after complained of being short on pay day.

High temperatures such as exist in boiler furnaces and absence of oxygen promote the decomposition of all hydrocarbons, including methane, the lightest of the paraffin series, one of the products of decomposition being soot.—*Bureau of Mines Bulletin No. 135.*

Gravity Track Systems at Anthracite Coal Breakers*

By F. N. RUPPRECHT
Wilkes-Barre, Penn.

SYNOPSIS—*Five typical arrangements of tracks at coal breakers and washeries are here presented. Local conditions dictate what general plan of trackage must be adopted. Sometimes local topography dictates a design inconvenient from the operating standpoint.*

IT HAS been estimated that in the United States nearly half a million freight cars are continuously employed in hauling coal traffic. All railroads derive some revenue from this trade, but with certain roads it is the main source of income. Such roads as a rule originate the coal traffic and are vitally interested in methods that prove most economical in handling cars. This applies with particular emphasis to the loading of cars at the mines and their subsequent making up into trains. This article deals particularly with the conditions and methods employed in the anthracite region of northeastern Pennsylvania.

Coal mining and transportation have a mutual attraction for each other. Wherever convenient, collieries are located on the main line of some railroad; otherwise, a branch is built to the mine. The former practice is preferable, since in a thickly settled rolling country the construction of branch lines is difficult, and high real-estate values render it costly. Frequently the haulage problem can be most readily solved by means of narrow-gage tracks either on the surface or underground, over which the unprepared coal may be taken to a convenient breaker. Nevertheless, an extended network of railroads traverses this coal region, upon which traffic moves in all directions.

Maximum Production Not Maintained

The annual production of somewhat over 80 million tons of anthracite in Pennsylvania is divided among many collieries. The daily capacity of these plants ranges from 500 to 3000 tons and more, but the maximum capacity is not maintained throughout the entire year. With an eight-hour working day the annual production of an up-to-date colliery will not average much over 500,000 tons. At the rate of 3000 tons a day about 70 cars will be required to move the coal, and 45 tons per car may be taken as an average of capacity. It may readily be seen that the cost of switching such a number of cars day after day for the purpose of loading them would be extremely high.

Collieries are usually constructed with the idea of giving service for fifty years, or even more. Consequently, a careful study of the requirements of each individual plant with regard to track facilities is necessary. As a general rule a colliery has upon one side the track or system of tracks, for holding the empty cars. These are known as the "light tracks." On the other side of the breaker is another track or system of tracks, for holding loaded cars, known as "loaded tracks." Scales are placed upon either side of the breaker, between the building and these systems of tracks, for the purpose of weighing both the empty and loaded cars. These are known respectively as the "light" and "loaded" scales.

The track connections and grades are so arranged that a locomotive places empty cars only above the breaker and takes out the loaded cars below it. For the purpose of loading, the cars are run beside or underneath the breaker by gravity. The movement of cars from the light to the loaded tracks is of course not continuous. They are stopped at the light scales for weighing, spotted at the loading chute and stopped again for weighing on the loaded scale.

Grade of 1½ Per Cent. Most Desirable

The placing of empty cars and the removal of loaded ones do not interfere with the operation of loading or weighing in the least. The tracks running through the breaker and over the scales are not intended for locomotives so far as the curves and track materials are concerned. In a like manner the scales are constructed only to weigh cars and have no dead rail to permit a locomotive to cross over them.

Experience has shown that a grade of about 1½ per cent. is the most desirable for the operation of these gravity track systems. Under favorable conditions cars will run on a 1¼ per cent. grade, or even lower, but around sharp curves and over comparatively rough tracks, also for operation in winter, anything less than a 1½ per cent. grade proves insufficient. On the other hand, grades much in excess of 1½ per cent. will make it comparatively difficult to stop the cars upon the scales or under the breaker chutes.

The accompanying illustrations show typical track arrangements at coal breakers. They may be grouped into four distinct classes, the chief difference being in the method in which they are connected with the main track.

From an operating standpoint the most desirable method is to make connection with the main line for both light and loaded tracks, as shown in Fig. 1. In this arrangement, however, it is difficult as a rule to secure the necessary 1½ per cent. grade adjacent to the main line without resorting to a hump in the light track connection, a depression in the loaded track connection, or possibly both. Furthermore, if the main line has a low grade, the approach to the hump will be of considerable length and require a large amount of track. Finally, the distance between the light and loaded track connections on the main line will be increased. It will thus be only in rare instances, where the ground ad-

*Abstracted from "Engineering News-Record" of May 23, 1918.

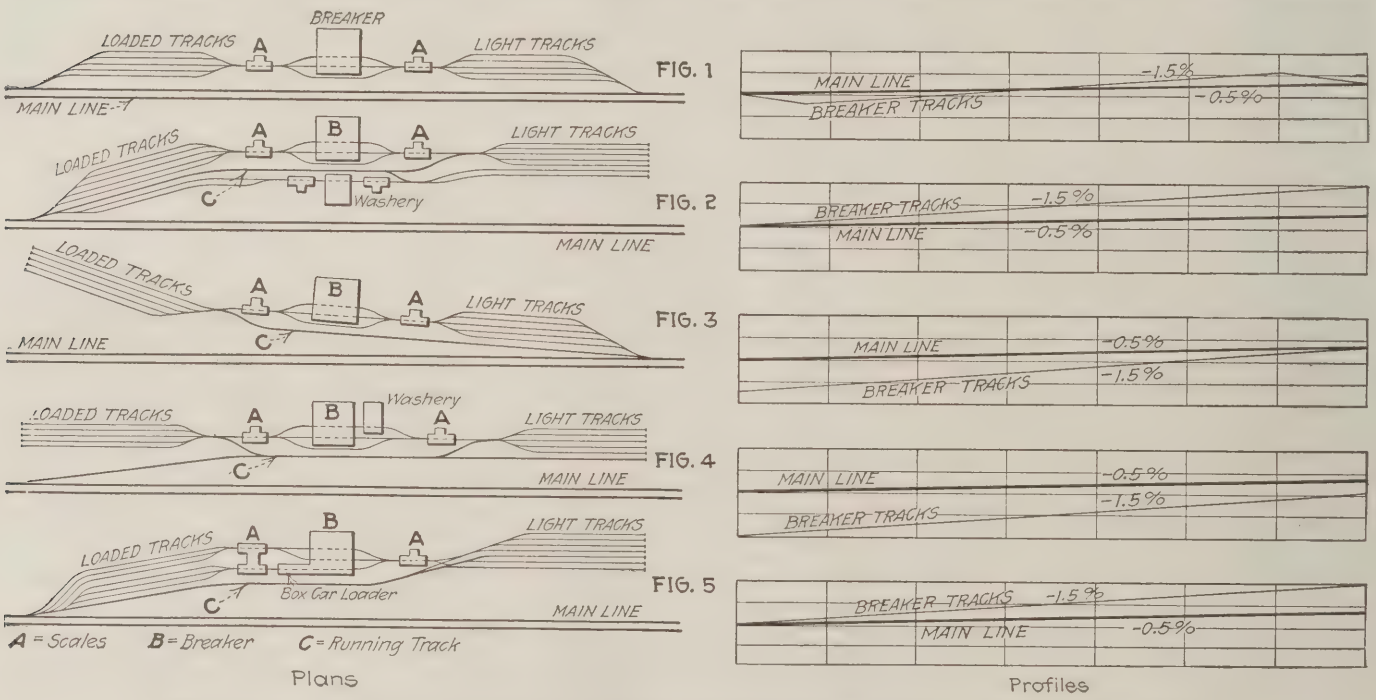
jacent to the main line is favorable, and where the required right of way will be available for such a purpose, that an installation as shown in Fig. 1 can be made.

Track systems with connections at both ends are always expensive to install, and it is doubtful if the advantages from an operating standpoint are of much significance.

The method most frequently employed is to provide a direct connection from the main line to the loaded tracks, as shown in Fig. 2. A thoroughfare, or running track, is built alongside the loaded track to a point above the light scale where it connects with the light tracks. The only disadvantage of this construction is that it interferes with the continuous loading of cars when the locomotive places the empties on the light track. However, this operation takes only a comparatively short time, and if convenient can be carried out when the breaker is idle.

The advantages in the construction of this type of track system will readily be appreciated. This layout is quite flexible and can be fitted to local conditions in most cases. Since the grade of the track can be raised or lowered to fit the ground the grading is reduced to a minimum, while at the same time it is not necessary to have the breaker tracks parallel, or even approximately parallel with the main line. They may curve in any direction and be kept upon ground best suited for the purpose. The high ends of the light tracks are not connected with each other. It would be useless to make such a connection. Moreover, the stub ends save car capacity and reduce the length which would otherwise be required for the light tracks and the track system in general.

Fig. 3 shows a layout in which the light tracks are connected with the main line. This construction is not as desirable as the one just described, the main objection being that the locomotive does more or less switching when the loaded cars are removed. This switching necessarily interferes with the running of the loaded cars onto the loaded tracks immediately after they have been filled with coal. Whenever convenient the loaded cars should be taken away during the hours when the breaker is not in operation. Generally, however, there will be more interference in removing the loaded cars than in placing the empties on the light track. In this type also loaded cars have to be hauled up a steep grade when they are removed from the colliery.



Such a track system as this is resorted to in places where the main line is on a high embankment, and where it is desired to construct the breaker on low ground beside it. In flexibility of construction there is no difference whether the light tracks or the loaded ones are connected with the main line; the difference lies in the operation alone, as has been shown.

A track system not frequently employed is shown in Fig. 4. Here the far ends of both the light and loaded tracks are disconnected, and both the operations of placing empties and removing loads will result in interference with the continuous loading of cars, because the only access to the track is over the connections alongside the breaker. Moreover, a reverse movement is necessary, either in placing empties or removing loads, depending on whether the loaded or light tracks form a continuation of the branch leading to the colliery.

From an operating standpoint, therefore, this track system is not desirable. Its advantage lies in the fact that for the same car capacity it will require less space than any other system, and that it can be readily adapted to the various conditions of insufficient right-of-way and unfavorable topography.

A construction of this type will usually be found some distance from the main line of a railroad, the difference in elevation between the main line and the colliery track determining to a considerable degree the location and grade of the branch line.

At the present time many washeries usually located adjacent to collieries are reclaiming coal from the old

FIGS. 1 TO 5. TYPICAL RAILWAY TRACK SYSTEMS AT ANTHRACITE-COAL BREAKERS

culm banks. A considerable number of these banks, however, are located at points where the collieries have been abandoned. In such cases the tracks serving the washery are extremely simple, as the capacity of such a preparation plant is only a few hundred tons a day.

Frequently a single track without scales is laid either through the washery, or beside it, the grade being made such that the cars may be moved by gravity after they have been placed by locomotive.

Where a washery is operated in conjunction with a breaker it is highly desirable to have this washery located beside the breaker, provided there is sufficient room. In such a case there will be no duplication of facilities, and the washery will be benefited by all the advantages secured from the breaker track system. It is not always possible, however, on account of lack of sufficient space to effect such a location, and frequently the washery is placed on the opposite side of the running track, as shown in Fig. 2.

Tracks serving a washery are constructed on the same principles as those serving a breaker, and parallel with them, although of course the capacity will be much less.

Sometimes existing collieries are overhauled, equipped with improved machinery and the capacity increased. In such a case it is necessary to provide additional tracks to take care of the increased output. The track system already existing and designed with the intention of occupying as little space as possible may present a difficult problem when extensions are required and expenses must be kept down.

If it is impossible to add length to existing tracks, which is not uncommon, the only alternative is to construct new tracks paralleling the existing ones, and make the best connections possible.

Fig. 5 shows a satisfactory method of adding to the capacity of a track system which could not be extended in length. Each group of light tracks has to be accessible to the running track (for the purpose of placing empties) as well as to the light scales. This results in a set of crossing frogs. The loaded track additions require the construction of a second loaded scale, so as to use all of the available space.

The total capacity for which the light and loaded tracks should be designed will depend not only on the capacity of the colliery, but also to a considerable extent upon operating conditions. After the daily capacity of the plant goes beyond a certain number of cars, which may be handled by one locomotive, the capacity of the tracks may have to be only slightly in excess of this, because the switching service can be so timed that empty cars will always be on hand. For instance, a train of empties may be placed early in the morning and another one early in the afternoon.

The rail employed in the construction of breaker tracks is usually "relayer," and in places where the track is not traversed by locomotive this may be as light as 62 lb. per yard. Turnouts through which locomotives run are usually No. 8's; but those which only take cars may be No. 6's or even No. 5's. In order to save as much room as possible turnouts are frequently designed on the style of the old three-throw stub switch, except that the two switches are about 25 ft. apart and the frog is not in the center of the main track.

Formerly scales 38 ft. long were ample, but at the present time the length of cars has been increased so that 42-ft. scales are too short, and 50-ft. scales are being installed.

To facilitate the filling of box-cars, which are quite common nowadays, to their full capacity, box-car loaders of various types are being employed. One type of this device consists of a vertical turntable on which the cars are placed and revolved through a vertical arc, first one end of the car being lowered and filled with coal and then the other.

FIGS 6 AND 7. LIGHT TRACKS SHOWN IN THE LEFT-HAND VIEW, LOADED TRACKS IN THE RIGHT

Modern collieries also have facilities for the economical handling of condemned coal. Cars condemned for having too much slate are taken by locomotive from the loaded track and replaced on the light track. From here they run by gravity over a hopper pit, just above the breaker, where they are emptied and again spotted for loading. The condemned coal is taken by a conveyor back into the breaker for retreatment.

One of the outside tracks of the breaker is frequently used for the unloading of supplies of various kinds, such as mine props. Sometimes, also, there is an extra track leading to the power house, where fuel may be unloaded. Provision for such track forms a variation in the layouts as shown in this article.

The temperature in a boiler furnace is about 1400 deg. C. At this temperature oxygen reacts with the combustible material to be burned very rapidly, but proper conditions for reaction must be provided.—*Bureau of Mines Bulletin No. 135.*

Some Reasons for Industrial Discontent*

By IRVING FISHER
Professor of Political Economy, Yale University

IN ORDER that labor shall be contented we must understand the psychology of the workingman. We must satisfy his great fundamental human instincts. I believe there is a field for what might be called industrial psychiatry. I have talked about this often in my classes but have been rather hesitant to say anything about it publicly; until recently I have discovered that a number of other people have been working along the same line and have reached substantially the same conclusions.

Among these is at least one practical employer of labor, Robert B. Wolf, who has shown, in the wood-pulp industry, that it is possible to make the work itself interesting to the laboring man. I believe that herein lies the hope of solving the great industrial problem of labor discontent more than in any other direction. I think that if employers would join Wolf and the few other employers who have gone into this line, studying the psychology as well as the physiology of labor, and try to adapt conditions of work to the needs and yearnings of labor, labor discontent will be diminished far more than by any other method I know of.

Must Satisfy Fundamental Human Instincts

As I see it, any human life in order to be a successful human life, must satisfy six or seven of the great fundamental human instincts. In my classes I have been enumerating them as follows: First, there is the instinct of self-preservation, about which little needs to be said, because we all recognize it. The trouble is, we harp too much on that one string. We think that is all the workman is interested in; that his interest is confined to his pay envelope. Undoubtedly that is the most fundamental thing. But there is also the instinct of self-expression, or the instinct of workmanship; there is the instinct of self-respect and respect for others; there is the instinct of self-sacrifice or heroism; the instinct of love, or the home-making instinct; the instinct of loyalty; and possibly, whether it is innate or not I do not know, the instinct of worship. If we examine the misfits of life, those who fill our insane asylums, our prisons, our hospitals, you will find that they are made up of people who have not been able to satisfy all, or possibly any, of these fundamental instincts.

In order that the laboring man may live his life, he must satisfy something more than the instinct of self-preservation. His life cannot amount to much if it merely consists in keeping body and soul together. And yet, with strange blindness, the employer assumes that the only thing his employee is, or can be, interested in is his wages. Hence these ingenious schemes, like the Taylor system, for trying to get more work out of labor consist entirely of thrumming on this one string—trying to hold out a bale of hay for the donkey, and as he approaches it, making him walk the faster to reach it. I believed thoroughly in these systems, and in piece work, until I began to understand what at first had appeared to me strange, the objections on the part of the laboring men, though they did not and do not themselves understand the nature of their objections. Their souls are hungry and thirsty to satisfy these great instincts, but they do not know it.

Now, what Robert B. Wolf did was to restore, in the first place, the instinct of workmanship, which has been subtly abstracted from industrial life through specialization of work and division of labor. Originally a man was interested in his product, just as an artist is interested in his picture. But today, with the minute division of labor, a laboring man sees his work sweep by him, a peg in a shoe, a bolt in an automobile, and since he is not able to visualize his part in the product his work ceases to be interesting and becomes drudgery.

He wants to shorten his hours; and the employer, whose work is interesting, whose work is his life, cannot understand why the employee is always trying to shirk, whereas he himself is willing to work twelve or sixteen hours a day. The reason is that in one case the instinct of workmanship is satisfied and in the other case it is not. I have sometimes thought how much wages I would have to be paid to give up my job to put pegs into shoes or to take up other monotonous work.

If you paid me $1,000,000 a minute, I would not give up my work and go into an automobile factory or a shoe factory. I might for a few minutes! But if it meant sacrificing my life work, I would prefer suicide, after having had a taste of the satisfaction that comes from doing work which I love.

Each Man Shown His Particular Work

What Wolf did was to show each of these men, or some of them, what their own particular work was. At first he tried to introduce the Taylor system, but those associated with him practically forbade it. So he put into operation a system of charts whereby men could record by a series of curves just what was happening at each stage of the process. They watched their records, and did more work than could have been gotten out of them by the Taylor system.

The men in this wood-pulp factory have to raise gradually the temperature of the cookers into which the chips go, keep the temperature there for a certain number of minutes, then raise it again, and so on through a certain cycle in order to get the results. Eight years ago when Wolf went into this plant they were making, if I remember correctly, with a certain equipment 100 tons of the worst wood pulp in the country.

Today, with the same equipment, they are making 200 tons of the best, and the transformation has been due to giving these men a record of their work and getting them interested in bettering this record. Meanwhile, wages have arisen 40 per cent.; there have been no strikes; the men are loyal to the organization; and the industrial problem has been largely solved.

All day these men trace with a lead pencil their work. Their own part in making that wood pulp is that little

*Closing remarks in the presidential address of the American Association for Labor Legislation delivered at its eleventh annual meeting held in Philadelphia, Penn., Dec. 27, 1917. The title of the address is "Health and War." Copies of the unabridged address are being distributed by the author.

picture or graph. And they are just as much interested in making that picture every day as an artist is in painting a new picture. It is theirs. They get credit for it from their fellows and in the eyes of their boss.

There is more in the system, because Wolf has tried to satisfy also the other great natural instincts, the instinct of self-respect and respect for others, the instinct of loyalty; making them feel as though they were human beings—his brothers, instead of a lower order of human beings interested only in their pay envelopes.

Would you try to limit the instinct of a soldier merely to his pay envelope? Would you try to make a soldier go over the top by bribing him? Suppose President Wilson had said to General Pershing: "Now, Pershing, I want to be sure you are always on the job, and not skimping it. I have developed a Taylor system by which your wages will go up or down according to your victories."

What do you suppose Pershing would have said? He would have said: "Mr. President, what do you take me for? Of course I must live. But I am not primarily interested, or only interested, in my pay envelope. The motives which are sending me to France are loyalty to my country, heroism, the desire to sacrifice myself, to satisfy my instinct of self-respect and the respect of others, and may be to win some glory. Idealistic motives spur me and keep me at work."

And now we are taking men out of the factory and sending them into the trenches, when the only stimulus we have played upon in the factory has been the pay envelope; and yet these same dormant higher motives are there and will operate to make good soldiers. They could be enlisted to make good workmen. I hope that this may be one of the lessons of the war.

After this war we must apply science to industry, in a way to make industry more wholesome and healthy; which means not only better sanitation and ventilation, not only how to make the workman keep his bodily functions going properly, but how he may obtain mental health so that he may live, as Professor Alfred Marshall says, a complete all-around life. And if we are to say that the world owes every man a living we should mean not only that it owes him wages but also that it owes him the full expression of the fundamental instincts of a human being.

Storage of Bituminous Coal

The more general storage of coal during the spring and summer months is coming to be recognized as the only practical means of avoiding a coal shortage during the winter. Many corporations and individuals will this year undertake, for the first time, to store large quantities of coal.

The storage of bituminous coal presents certain difficulties because of its tendency toward spontaneous combustion with its attendant dangers and losses. The methods to be employed in avoiding spontaneous combustion have not generally been well understood and those which have seemed successful in some cases have failed in others.

The Engineering Experiment Station of the University of Illinois has just completed a study of the problems involved in coal storage and has published the results in a 200-page illustrated book designated as Circular No. 6, "Storage and Bituminous Coal." The study was made under the direction of H. H. Stoek, Professor of Mining Engineering. The reasons and advantages of storing coal are given, the kinds and sizes of coal which may be safely stored are described, and the many factors entering into successful storage are discussed.

Copies of Circular No. 6 may be had by addressing the Engineering Experiment Station, Urbana, Illinois. The price is 40c. a copy.

HELP YOURSELF

BY RUFUS T. STROHM

WE'RE apt to be filled with envy
At the mention of the chap
Whom circumstance, by a lucky chance,
Has tossed into Fortune's lap;
For the ordinary mortal
Is a poor and hapless elf,
And the best that he can expect to see
Is a way to help himself.

IT'S a comfort to the climber
Who would scale the mountain wall
To know a friend is at hand to lend
Swift help should he chance to fall;
But the man who scans most keenly
Each inch of the rocky shelf
Is the lonely wight on the dizzy height
Who is forced to help himself.

THE strides that the race is making
In its struggle toward the light
Have come by the throes and the sweat of those
Who have had to work and fight;
For earth doesn't owe its progress
To the Guildford or the Guelph,
But in shire and town to a Jones or Brown
Who has learned to help himself.

THE gawk who inherits millions
Has a cheap cause to be vain,
Since not one sou of the sum is due
To his use of brawn or brain;
But the engineer who labors
As he garners in the pelf
Has the cheering thought that his wealth is wrought
By the way he helps himself.

Reprinted from "Power."

To Enforce Loading of Clean Coal

The following new regulations, which are expected to insure the production of clean coal, became effective on June 1:

No bituminous coal will be permitted to be sold, shipped or distributed if it contains such quantity of rock, slate, bone, sulphur, fireclay, shale or other impurities that it would not have been considered merchantable prior to Jan. 1, 1916.

Shipments from bituminous coal mines in which the coal is naturally of such character as to be unfit for market may be prohibited by the Fuel Administration. Operators of bituminous mines whose products are capable of being made merchantable by complying with the requirements of the Fuel Administration in regard to the removal of impurities, and who fail to comply with those requirements, will be required either to unload and clean such coal, if it has been loaded into cars or bins, or to deduct 50c. per ton from the Government price. In the event of repeated violations on the part of such operators, such further action will be taken by the Fuel Administration as it may deem advisable.

The enforcement of these orders devolves, primarily, upon inspectors appointed by the district representatives. These inspectors are required to familiarize themselves with the conditions under which coal is produced and prepared for market in the particular territory to which they are assigned, and to advise mine operators and employees of such methods as the inspectors may deem necessary to bring coal up to the standard; to inspect coal-mining operations in their respective territories; and to make daily reports to their several district representatives.

Copies of these reports, with the recommendations of the district representatives thereon, will be forwarded to the Fuel Administration for final action.

The United States Fuel Administration also made public an order under which operators of bituminous coal mines may receive a special allowance for coal mechanically washed or extraordinarily cleaned or picked in such manner that the fuel value of the coal will be substantially increased by the removal of waste and impurities. No special allowance, however, will be made for the ordinary method of cleaning or picking coal

The amount of the allowance contemplated by this order will be determined by the Fuel Administration, and will be set forth in a permit to be applied for and obtained by such operator in conformity with the provisions of the order.

Coal-tar products, valued at nearly $200,000,000, were produced in the United States in 1917, it is announced by the United States Tariff Commission, which recently completed a census of the coal-tar industry.

New Coal Prices in North Dakota

New prices for coal produced in North Dakota have been fixed as follows: South of the 12th parallel, run-of-mine, $2.25; prepared sizes, $2.50; 6-in. steam lump, $2; slack or screenings, $1.25. North of the 12th parallel, run-of-mine, $2.70; prepared sizes, $3; 6-in. steam lump, $2.50; slack or screenings, $1. The wage allowance of 45c. may be added to the prices.

Delayed Coal Delivery Causes Discontent

Considerable discontent is evidenced by domestic consumers, judging from letters reaching the Fuel Administration, because deliveries of coal are not being made. The Fuel Administration is trying to call every one's attention to the fact that, while it is very necessary to place orders now, this does not carry with it assurance of immediate delivery. The booking of the orders is a necessary factor in the working of the Fuel Administration's plan, and every precaution is being taken to assure adequate supplies to all domestic consumers this winter. It would be unwise in many instances, of course, to interfere with essential transportation to deliver coal which will not be used for several months.

Weekly Production Statistics

Bituminous coal production reached a new high point during the week ended May 25, when it exceeded by 6000 tons the production of the week ended May 11. The total production for the week was 11,811,000 tons. Anthracite forwardings fell off slightly as compared with those during the week ended May 18. The total forwardings during the week ended May 25 were 40,752 cars.

Beehive coke production fell off 2 per cent. The output during the week ended May 25 was 664,000 tons. Byproduct coke production during the week under review was 484,333 tons, a slight decrease over production during the preceding week.

Telegraphic advices regarding production for the week ended June 1 indicate that there will be a sharp decline in production for that week. This is due largely to the observance of Decoration Day as a holiday. The foregoing estimates are those of C. E. Lesher, the geologist in charge of statistics for the United States Geological Survey.

Dr. Garfield Appoints General Solicitor

W. T. Alden, a Chicago attorney, has been appointed general solicitor for the Fuel Administration. Owing to the growth of the Fuel Administration and the development of its functions, the work of its legal section has assumed large proportions. It interprets and defines the jurisdiction and powers of the organization under the law and prepares all executive orders and regulations. This is in addition to widely extended activities through the various sections of the administration.

Lack of Orders in Western States

Mines in Iowa during the week of May 18 lost 13.5 per cent. of their production due to lack of orders, according to the Fuel Administration. Losses were shown in other Middle Western and Western states for the same reason. This condition could be avoided, Dr. Garfield states, if domestic consumers would place their orders at early dates. A large portion of the domestic orders in the bituminous consuming region have not been placed. Losses, attributable to that cause in other states, during the week of May 18 are as follows: Rocky Mountain states, 10.8 per cent.; Oklahoma and Arkansas, 4.3 per cent.; far western states, 2.8 per cent.; Kansas and Missouri, 2.6 per cent.; Indiana, 2 per cent.; Illinois, 1.4 per cent.

Allotment of Anthracite Now Fixed

Anthracite production during the coal year, which will end Apr. 1, 1919, will be 89,000,000 long tons, it is estimated by the Fuel Administration. Of this amount, 54,345,783 long tons, it is expected, will be available for domestic consumption. This is 5 per cent. more than was distributed for domestic purposes during the last coal year. The difference between the total production and that available for domestic consumption represents the amounts used at the mines, by industries and by the railroads.

New England is to receive 16.95 per cent. more anthracite for this year's consumption than was used in that section last year. The Atlantic states have been allotted 12.69 per cent. more than they had last year. Canada will receive 6.59 per cent. less anthracite than last year. Reductions also will be made in the supplies for the Middle West and the Northwest. None will be sent west of the Mississippi or south of the Potomac and Ohio Rivers.

Coal Distribution Plans Now Complete

The matter of fuel priorities is rapidly assuming its final form. Some of the brightest minds, both in and out of the Government service, have been working on this question. No attempt is being made to conceal the fact that many of the nonpreferred industries will be severe sufferers from lack of fuel this winter. There will not be enough coal to go around. Instead of the uncertainties of last winter, however, systematic distribution will be made. Domestic consumers and the preferred industries will have coal enough. Plans, which give this assurance, already are complete.

No Anthracite for Industrial Plants

Use of anthracite coal for steaming purposes was an important contributing cause to the shortage of domestic fuel in New England last year, the Fuel Administration believes. For this reason, an order has been issued forbidding any dealer to deliver anthracite to an industrial concern without a certificate of exemption from the Federal Fuel Administrator.

To Solve Car Distribution Problem

With the railroad fuel matter settled, officials of the Railroad Administration and the Fuel Administration are engaged in working out plans for the distribution of cars. While "a car is a car" under the present plan, which abolishes assigned cars, there nevertheless are numerous problems which must be solved. One of these is the treatment to be accorded privately owned coal cars. There is one company which owns $4,500,000 worth of cars. No solution in this matter has been reached, but it is probable that the company owning the cars will be given the privilege of using as many of them as can be handled without delay, but none of them will be allowed to stand idle.

Effort Made To Insure Clean Coal

While numerous cars are being found to contain dirty coal, it is pointed out at the Fuel Administration that the great majority of operators and workmen in the mines are being more than ordinarily careful to send out clean coal. The cases where this is not being done are regarded as exceptions and rapidly are being ferreted out. The penalties being imposed are having the effect of straightening the matter out where there have been delinquencies in this respect.

An increased force of inspectors is now in the field for the Fuel Administration. As it is inconceivable that any mine operator or mine workman should be unaware of the imperative need to conserve railroad transportation facilities, no leniency is to be shown in cases where an undue percentage of dirt has been loaded with the coal.

Brief Washington Notes

A fuel administrator for Alaska probably will be named in the near future. At present the Alaskan field comes under the jurisdiction of the state administrator for Washington.

Great difficulty is being experienced in meeting the rapidly increasing demand in the East for smokeless coal. That the Fuel Administration was justified in restricting the use of this class of coal and in cutting it off from Chicago and other cities is held to have been demonstrated.

F. J. Goodfellow, of Bradford, Penn., has been named a district representative of the Fuel Administration for the charcoal-producing region east of the Mississippi. A need for a more systematic allotment of charcoal became evident and Mr. Goodfellow was entrusted with its administration.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

In all parts of the Union labor is working steadily on all occasions when cars are provided. In some places, however, no great enthusiasm is being shown. Short hours and total absenteeism make it impossible to secure the maximum tonnage of which the mine-working force is capable. The men in some cases do not visualize the war, nor do they feel any incentive driving them onward to maximum production.

In a recent issue of the *United Mine Workers Journal* an account is given of the subscriptions of the mine workers in Washington to the Third Liberty Loan. In some towns where there are a number of people not engaged in mining the quota was largely over-subscribed. In Carbonado, for instance, the subscription was 733 per cent. above the quota. But quotas are quite deceptive bases for estimation, and the possibility of a number of nonmining contributors cannot be overlooked. Casting out these records, however, we find that 129 men at the little town of Tono, in Thurston County, just south of Seattle, purchased $23,000 of bonds—just $178.29 per man. But the little town of Fairfax, in Pierce County, did better. Fairfax's contributors only numbered 62 men, but they bought $17,000 of bonds, or $274.20 per man. Talk about "lengthening the worker's stride"—you couldn't lengthen that stride much. It is a long jump in itself—such as a Westerner might be expected to take. Three hundred men at New Castle did not do so well, but even they subscribed for $18,000 of bonds, or $60 apiece. Men who buy bonds like the men of Tono and Fairfax must be and will be workers. They live rigorously and work stupendously that our Nation may live and not die.

> **MY KNOWLEDGE of the miner leads me to believe that, given the proper opportunity, he is willing and anxious to enter into team work with his employer, the Government and all concerned. Only by this method can maximum results be obtained. The miner has always been a man who loved his independence, and approached in the proper spirit he can be relied upon to contribute his full effort. He will coöperate, but cannot be driven. In this spirit of coöperation the sucess of the mining industry, as well as of all other industries, lies. The coal operator who desires to obtain the best results from his men should approach them in this spirit, and the response will be wonderful.—John P. White at International Railway Fuel Association meeting.**

Sergeant H. Austen Beck, formerly of the 1st Battalion, Canadian Infantry, has for two months been aiding the United States Fuel Administration by making speeches in coal-mining villages. He is the son of N. D. Beck, Supreme Court Justice of Alberta, Canada. Invalided by reason of shell shock and gas, he has been able to tour West Virginia, Tennessee and Kentucky towns.

He says: "If there is any lack of patriotism in the United States it can be charged to ignorance of the true conditions in France. The miners and other workers in the little out-of-the-way places are hungry for news. The Fuel Administration sent us, four returned soldiers of the speaker's staff, at the invitation of a committee of workingmen to mining towns in West Virginia and Tennessee. In many of these places we were the first visitors who had actually been in the fighting. In Pruden, Tenn., the miners increased their output by 300 tons the day following our visit and planned to continue this good work. At Petros, where the Tennessee state mine is located, we read the President's "Buy another bond" slogan. As a result, the town's quota was oversubscribed thirteen times."

To this testimony nothing need be added. Where the truth is apprehended the response is unquestioned. The Evans Coal and Coke Co., of Connellsville, Penn., with about 250 men, announces that every man contributed to the second war fund of the American Red Cross. The contribution was $100 from the company and from the employees $524.25. The Illinois and Kentucky papers will please not copy this item. Our news notes of May 25 exhibit how much larger was the offering of Illinois, and the Labor Situation of the same date showed how much more generous was the outpouring from Kentucky. Yet the Evans men stand well above many of their fellows in Pennsylvania.

In the anthracite region the mine workers of the Hillside Coal and Iron Co. and the Pennsylvania Coal Co., Erie affiliations, gave the Red Cross $16,000, the Ewen mine leading with $2815. The larger contribution is somewhat over $1 per head. As the average for the whole country was $1.75 per capita and $4.25 per person employed in industry, the gift does not appear commensurate with that made by others.

The gross income of the American people is said to be $40,000,000,000 a year. The Red Cross apparently secured from out of this $175,000,000, or about $1 in every $229. Thus the average gift of the American people was one day's income in every 9 months of steady work. Judging by this the Illinois mine workers who promised a dollar a month and the Kentucky men who gave a full day's work sensed the nature of their obligations with fair accuracy.

A Red Cross four-minute man in New York City somewhat startled his audience the other day by appealing for their nickels and dimes. If it be true that 6,000,000 people in that city gave about $34,600,000 and that 40 per cent. of the people receive an income from services rendered, then the amount contributed was $5.75 per person and $14.40 per income-receiving unit. From this it will be seen that people are giving generously—not in dimes, but in days, some even in weeks, of income.

In reply to an inquiry Van Bittner, president of District No. 19, informs us that every member of the United Mine Workers of America in that district, which comprises southeastern Kentucky and Tennessee, gave to the American Red Cross the proceeds of the first day's work performed during the week of May 20, in accordance with instructions issued by the district officers of the United Mine Workers. Owing to this generous contribution the coal mining districts of southeastern Kentucky and Tennessee oversubscribed their Red Cross quota 500 per cent.

At the Dorrance colliery of the Lehigh Valley Coal Co., near Wilkes-Barre, Penn., the mine workers cornered Stanley Brucchi, a man about 45 years of age, and demanded that he withdraw his positive refusal to contribute to the Red Cross. When he repeated his declaration Brucchi was grabbed and hurled into the colliery reservoir. After a good soaking he consented to make a contribution to the Red Cross.

As stated May 25, the Maxwell No. 2 colliery of the Lehigh & Wilkes-Barre Coal Co., at Ashley, recently had a strike. A second suspension for substantially the same reasons laid the mine idle May 28. The strike lasted two days and caused a loss of tonnage of about 2500 tons. On

May 29 the men agreed to go back to work if certain demands were immediately met by the company. This second strike seems to have caused a severe split in the ranks of the men, the president of the local, Thomas Moran, resigning, and another man being elected in his place.

The officials in District No. 1, the northern district of the anthracite region, are determined to prevent locals from calling strikes that violate existing contracts between the union and operators. They have instituted proceedings against the officers of a local at Laflin, Luzerne County, charging a misuse of the funds of the local treasury in the conduct of an illegal strike. The union has given the officials an opportunity to return the misappropriated funds. Seven of the 16 officers of the Ridgewood colliery local were arraigned on May 29 before an alderman, the auditor of the United Mine Workers of America charging them with conspiracy and of receiving money under false pretenses. The men were held in $500 bail.

The illegal strike mentioned was against a certain foreman, to whom the men took exception, and it lasted from Jan. 17 till Feb. 18. During the course of the strike the local officers paid money to committeemen who were engaged in attempts to prevent other men from displacing the strikers. Eight of the officials thus offending have refunded the money, but there are still seven that the union deems should make a return of monies believed to be wrongfully expended. The United Mine Workers say they will take the case to the highest courts and make every effort to obtain a conviction.

Still the Hard-Coal Men Will Button Strike

The Honey Brook No. 5 colliery of the Lehigh & Wilkes-Barre Coal Co., at Audenried, is also tied up by a strike. This mine is in the Beaver Meadow district near Hazleton—a long way from Ashley, which is in the Wilkes-Barre field. The strike has been called by the local union because some of the members of an Italian local would not pay their dues. The men have been termed members of the Industrial Workers of the World, but that is not true. They are merely delinquents who will not pay dues either to the local union or to any other organization. By this strike about 500 men lose several days' pay and the country loses thousands of tons of coal, all to balance the books of a small local.

The Huntingdon and Broad Top Region has, at least temporarily, composed its troubles and none too soon, if it be true, as stated, that a riotous disposition developed among the miners which made the mine owners at Rockhill apply to the sheriff for a force of deputies to protect the works. The disaffected men, it is said, tried to induce the pumpers to leave their jobs and let the mines flood with water. The State Police assisted the sheriff's deputies in keeping order.

Broad Top Men Consent to Await Arbitration

However, after three weeks of idleness, the 2600 men decided that they would go back to work. Representatives of the mine workers on Friday, May 31, and on Saturday, June 1, held an extended conference in Washington with Fuel Administrator Garfield. The Fuel Administrator took the position that production must not be interrupted pending the adjustment of the controversy.

The officials of the union returned to the Broad Top Region with Rembrandt Peale, one of the representatives of the Fuel Administration. At a meeting of the representatives of the various locals June 4 the delegates unanimously voted to return to work pending arbitration of the matters in dispute.

The strike was called for the purpose of enforcing the continuance of an agreement to pay a bonus of 10c. a ton which was in effect last year and which the operators contracted with the men to pay till the first of April. When that date arrived the operators reduced the rate of pay and the men, for a while, continued at work but finally struck about May 9.

President W. M. Rodgers, of the Monongahela Valley Labor and Trades Council, of Fairmont, and president of the West Virginia Federation of Labor, stated recently that a conference was held a few days ago at which C. W. Watson, George T. Watson, J. O. Watson, Frank J. Hayes, president of the United Mine Workers; R. C. Valentine, of the Official Board; Frank Keeney and Fred. Mooney, president and secretary of District No. 17, respectively, were present. It was agreed that there should be no blocking of the organization in northern West Virginia. Six or seven organizers are hard at work in the Fairmont district and the organization seems securely planted at several mines; P. K. No. 25 being one of the first.

The hope that Madison County, Illinois, would renovate itself in the world's opinion by convicting the 11 men charged with the murder of Robert Paul Prager, a German enemy alien, in the name of loyalty, was not realized. Though one of the defendants had confessed that he was the leader of the mob and though strong evidence was presented against the others, the jury on Saturday afternoon, June 1, returned a verdict in the Edwardsville Circuit Court acquitting all the defendants and this after being out only 45 minutes.

While he denied that his clients killed Prager he contended that the man was killed by "good loyal citizens, men of middle age, who feared that their lives were in danger when working in the mines," yet 8 out of 11 defendants, including Joseph Riegel, the confessed mob leader, were coal miners.

Prior to the lynching, which took place at Collinsville Apr. 5, Prager had tried to get into the miners' union at Maryville and statements attributed to him had been interpreted as hostile to the country and a suspicion was abroad that he wanted to get into the mines to blow them up. No proof was offered at the trial or elsewhere, however, in support of these rumors.

An "Unwritten Law" of Enemy-Alien Murder

In the trial "loyalty," as a synonym with "lawlessness," was invoked in every possible way. A frank effort was made to obtain the acquittal of the defendants under the unwritten law. Although Judge Bernreuter ruled that disloyal utterances, even if proven, afforded no justification for mob murder and though he excluded testimony intended to set up that sort of justification, the defense contrived to inject the "loyalty" question in one form or another, and the arguments of the attorneys for the defense were confined largely to a justification, on "patriotic" grounds, of the acts of the mob.

Riegel, who had confessed to the coroner's jury and to a newspaper reporter that he was the leader of the mob, repudiated both confessions when placed on the stand. He and most of the others claimed that they were innocent bystanders. The remainder denied that they were present at the lynching. There was wild disorder in the courtroom when the verdict was announced. Friends of the defendants cheered and an impromptu parade was formed, with the acquitted men marching as heroes at the head of the column.

Judge Bernreuter instructed the jury plainly that the war had nothing to do with the matter. It was simply a case in which a helpless prisoner was taken from jail and murdered. He declared that it was as unlawful to murder an enemy alien as to murder any other man.

Michigan is still restless. It lies so far off the beaten track of the coal miner that we are apt to overlook its activities. The miners are seeking in the Saginaw district an increase of 10c. a ton. Fuel Administrator Prudden, temporarily at least, refuses to concede it. Mr. Prudden met the mine workers' representatives about May 28 and they returned home to report. The miners have been favorable to a strike which was to start June 1, but apparently, on due consideration of what it would involve, the delegation did not favor any such action.

In Alberta, Thomas Biggs, the president of District No. 18, of the United Mine Workers of America, has settled the case brought against him by William Williams, a coal miner, by a complete apology. Williams had brought suit against Biggs charging criminal libel. He had also been suspended from the union and he brought an action against the Wayne local demanding reinstatement. This was also granted

EDITORIALS

NO ONE can deny that there would be undoubted charms for all of us in a state of things where every act we performed would be for the common fund and not for personal advantage. Little as the hope is that such an idyllic condition can ever be attained, we must never forget that in taking stock of motives there are two imperatives which make it possible to dream socialism though not to encompass it. These two imperatives, which have a great power and value in our present and immediate social life, are altruism and industrialism. Irving Fisher, professor of political economy, Yale University, in an article we publish this week, has called the former the instinct of self-sacrifice, or heroism; the latter he terms the instinct of self-expression.

The war has laid bare the first of these—the instinct of altruism. It is by no means dead in any of us. If socialism ever becomes something more than an academic theory of things that might be, it will be largely because of the instinct for altruism that lies in most of us, the natural craving for service that is deep-seated in the hearts of us all. During the present war this spirit has shown itself, first of all, in voluntary enlistment, then in the readiness of civilians to accept and perform unpaid service, later in the willingness of the public to permit of the conscriptive army, navy and aviation services, and to propose and support measures of taxation and price regulation of the most drastic kind.

It has been shown also in all forms of self-abnegation, in the purchase of bonds by people who thought far more of the service than of the investment, and in the generous gifts to the many great funds by which the works of mercy of a great war are made possible. The spirit of altruism, of self-sacrifice, of heroism, or of service, whatever we may term it, is still in the world however much in peace it may be overlaid by prudence and covered by a load of baser motives.

* * *

AND the other motive, that of self-expression, workmanship or industrialism, is not a bit less lacking. They who are socialists in name only urge that men are wedded to their fetters. They are indeed wedded to their work, but that work is usually no fetter. It is rather a labor of love. In this connection we may profitably study on page 1066 Professor Fisher's most interesting remarks on our social instincts.

Fisher has well said that a man in his work seeks something larger than the means of livelihood. He frequently hangs to his job because he has put his personality into it, because he feels also that in it he has accomplished something for somebody. If socialism ever comes about in "the rolling of the spheres," it will rely most on those who least believe in it—on the altruist, with never a bad word for his fellow, and on the plodder enamored of his task.

WE SHALL find the managers, secretaries and foremen of our great industrial organizations the backbone of our new institutions, as they are the backbone of the present institutions, as they must be indeed the backbone of all institutions however planned and wherever set in operation, if those plans are to arrive at a happy fruition.

No man in whom the instinct of getting, the instinct of crowding others, is plainly manifest has a chance in the conduct of a modern business for a modern corporation. We have long realized that men with such a viewpoint do not make good executives. A man must have the ideals of service and the love of good workmanship, in and for themselves, if he would fit into places of such trust.

Such men would be the very life of a socialistic condition, and not those who urge socialism so blatantly. The soap-box orators have caught hold of a holy thing and desecrated it by their worship. To them socialism is to be sustained by the spirit of greed and the spirit of envy, the only spirits to which they are subservient and which they understand.

* * *

BUT to what end is all this talk about a condition that is hopelessly remote if it can ever be—if indeed it ever ought to be. Just this. The spirit of service and the spirit of workmanship are integral parts of the spirits of men. No man is happy who cannot serve them in a degree. Community service gives a chance for the development of the first; therefore, foster that spirit in every mining village. Let every man have an opportunity for some free service to the community that this good spirit may grow in him, satisfy him and make him noble and happy. The employer will undoubtedly gain by this development, not only financially but in other ways. The employer, like his employee, has those nobler instincts which are only satisfied and fed by service and the opportunity for it, and the good which comes to his mining village will rest as a benediction on his own heart.

As to the spirit of workmanship, let its existence never be forgotten. Give every man a pride in his work. Let him learn the joy of high accomplishment. Let training be given, not for the purpose of creating discontent with the common round, but with the idea of making the work the man has to do worth while.

* * *

NOT every rookie has "a marshal's baton in his knapsack," and yet we train the private soldier. We do not drill and coach him with the idea of making a sergeant, much less a general, of him, though we would not begrudge him the place if he could fill it. No, he is drilled and instructed to the end that he may be a good soldier in the squad, and so that he may have pride in a soldier-like performance of duties. So also

in the industrial army. Every man should exercise body, mind and spirit in his daily labor. It should obsess all his powers, at least in working hours. It should elevate and inspire him. Its skillful accomplishment should feed not only his body, but his mind and his heart.

Because some men will never reach the place of leadership and authority is no reason for depriving them of the sustaining pleasure that comes out of the skillful performance of labor. Something of "art for art's sake" should enter into all our employments and give to them dignity and to their artificers mental and moral stature. Not the boss only, but the worker also, should be a craftsman in the art of mining.

An Accident That Never Occurred

THERE has been a great deal of ingenuity used to anticipate the possibility of accidents from acetylene lamps. There are dangers connected with them, of course, but they are less frequent and harmful than the dangers to be found in the use of other open lights.

The most unsubstantial of all charges against the system of lighting is the possibility of the acetylene entering into chemical union with the copper of the lamp, forming thereby a compound of such unstable character as to make a disastrous explosion conceivable. Strange to say, this accident never happens. It remains one of the unexperienced possibilities. Time surely has removed it from among the probabilities.

The danger seems to have had equal consideration in Great Britain with that it has received here. Henry Louis introduced the question of the danger at a recent meeting of the Institution of Mining Engineers of Great Britain. He advocated that acetylene lamps be always made of steel, tin plate or some similar metal, and said that copper and brass should be avoided. He added that a man with a brass acetylene lamp was running a risk he had no right to run. And yet he "freely admitted that he had never heard of an accident that could be traced to that cause." With the many real causes of accident, it seems purely academic to refer to the possibility of an accident, the like of which has never yet occurred so far as can be ascertained and would not in all probability do any extensive damage if it did occur.

William Maurice added that hundreds of thousands of brass acetylene lamps were in use, yet practical experience proved that no risk of the kind suggested was involved thereby. He stated that "the use of copper and brass vessels for acetylene lamps had been officially investigated in England, France and other countries, and it had been definitely and authoritatively stated that there is not the slightest risk in using brass vessels."

By scratching the inside of the copper acetylene lamp with a nail flashes of light have been obtained, but no explosion. The fact that the outcome of these flashes was not an explosion would seem to substantiate the notion that an explosion is entirely improbable. The choice of metals, therefore, should be based wholly on commercial grounds. If an iron or tinned container will give satisfaction there is no reason why it should not be used. Acetylene lamps, while quite inexpensive, have only a limited life and anything that reduces their cost will add much to their value and popularity.

The Submarine Menace

THE pirate Hun in his sneaking U-boats has appeared off the coast of the United States and has started his work of destruction on American shipping. It is interesting to note that one of the vessels escaping from the raiders was a steamer bound for New England with a cargo of coal.

Temporarily demoralizing as may be the effect of a submarine campaign waged upon this side of the Atlantic, it is at least gratifying to know that thus far the Hun has chosen here to play more nearly the part of a man. So far as is known to the general public, at least, his raids upon our commerce have been "decent"; that is, they have been in accord with the principles of international law and bear little semblance to the "frightfulness" of some of the sinkings that have been perpetrated across the Atlantic.

The present depredations of the U-boats are particularly interesting in that they may exert a powerful bearing upon the normal movement of coal by water to New England. It has been the intention and desire of the Fuel Administration to greatly increase this movement. The presence of undersea raiders may, however, render it necessary to move a greater tonnage all-rail than has been intended. A slow-moving collier or a tow of coal barges would doubtless be an easy prey to the Hun pirates. On the other hand, such a cargo should be easy of convoy and might offer a tempting bait wherewith to lure the adventurous submarine to within striking distance of destroyer, patrol boat or hydroaeroplane, any one of which is "bad medicine" for U-boats.

If convoy has to be resorted to—as may quite possibly be the case—it may not seriously decrease the tonnage transported. Groups of vessels under the protection of war ships are notoriously slow, for the simple reason that the group can move no faster than its slowest member. It will probably be quite possible, however, to so organize the movement of coal that vessels of approximately the same speed may be grouped together. Thus all the vessels in one convoy would move with about their normal rapidity.

An old adage has it that "forewarned is forearmed." We have lost a few ships at our very doors, we will doubtless lose more. In the meantime, however, means of protecting our coastwise shipping may have to be employed. The Hun U-boat should be no more difficult to hunt in American waters than in the North Sea or the Mediterranean. On the other hand, the submarine enemy is much farther from his base of supplies on this side of the Atlantic than on the other.

While the submarines are sinking a few unarmed schooners, tankers and the like, American shipyards are turning out vessels—real cargo carriers and war ships—at a speed never before equaled in the history of the world. Simultaneously, while the Hun puts dents in the Allied line—dents as expensive in men as they are useless strategically—the war cloud of Germany's new enemy grows even more formidable and threatening. The lightning from that cloud—that our enemies not so very long ago were wont to consider negligible—has already struck—at Cantigny.

Yet a little longer, and in spite of U-boats, massed offensives, frightfulness, "efficiency" and "kultur," we shall see the beginning of the end.

Hungarian Miner Invests All His Savings in Liberty Bonds

THE STORY OF JOHN DZUBER OF BLACKWOOD VIRGINIA

WHO BOUGHT LIBERTY BONDS TO THE VALUE OF $1200

JOHN DZUBER is 27 years old and has been 8 years in this country. He came from Hungary, but I don't believe he should be called a Hungarian any more. He married here some years ago, when he was working in the anthracite region. His child was born here and all the possessions he has were obtained here.

He is not sufficiently Americanized as yet, but he is going to be. He is learning every day and will get there sometime. John saved his money and was wise enough to know that he should keep his money in the bank, but when war was declared against Germany he was afraid to trust the bank and took out his money and put it in his trouser pocket.

Then came the Liberty Loan Campaign. John talked the matter over with the other miners and attended meetings, and he soon saw it was his duty as a citizen to help the boys "over there" to win the war.

He talked things over with his wife and Mr. Creveling, general manager of the Blackwood Coal and Coke Co., and finally bought $1000 worth of bonds for himself and $200 for his wife.

John Dzuber is some American, and there are a number of Hungarians like him in America.

DISCUSSION BY READERS

Loading and Shipping Clean Coal

Letter No. 9—Speaking of the frequent recent shipments of impure coal, to which attention has been called by numerous letters appearing in Coal Age, I want to cite an extraordinary case that has just come to my notice in the reading of *Fecony*, an interesting monthly publication of the Fuel Engineering Co. of New York.

The accompanying figure is a reproduction of the supplement of the June issue of *Fecony*, which we are kindly permitted to make. It represents a lot of material that was found in one two-horse truck load of coal, recently delivered to the steam plant of the Society of Useful Manufactures, having a central power station at Paterson, N. J. The truck was loaded from a car of bituminous coal that was shipped from Meyersdale, Penn. The scale of the photo is about 1 in. per ft. The over-all length of the exhibit, as photographed, being 5 ft.

SCRAP FOUND IN A 2-HORSE TRUCK LOAD OF BITUMINOUS COAL

The remarkable feature of this incident is the fact that so much scrap, including both bits of iron, wood, wire rope and cable employed in the operation of a mine, could find its way, either by accident, carelessness, or actual intent, into a car of coal loaded for shipment.

Such a thing seems incredible and, but for the evidence in the photo produced and copyrighted by the Fuel Engineering Co. of New York, it would be unbelievable. Through the agency of its little publication, *Fecony*, and the numerous sources of information open to it through the avenues of its business, the Fuel Engineering Co. have done much toward exposing the dishonest practices and unwise and unjust proceedings that have developed in the coal industry since this country entered the war.

The coal mines of this country, by the fortunes of war, are made the world's storehouse from which must come the fuel needed in the production and transportation of all war munitions and supplies. The output of coal must be maintained at its maximum efficiency.

——, N. Y. A SUFFERER.

Transportation of Coal by Canal

Letter No. 2—My attention has been called to the letter of W. G. Wilkins, which appeared in *Coal Age*, May 18, p. 938, asking for further explanation of the figures presented in my article regarding the practicability of utilizing the canal system of New York State for the transportation of coal.

Mr. Wilkins suggests that in any computation as to the cost per ton-mile of canal transportation, the expenditures made for canal construction, maintenance and repair, the maintenance and operation of the locks and dams and the sinking fund and bond interest charges should be included, and inquires whether the two mills per ton-mile rate, mentioned in my article was based on all of these charges.

In discussing the ability of the improved canals to transport a considerable volume of the anthracite and bituminous coal consumed in the area traversed by the canal between the Buffalo and the Hudson River, I made no computation as to the exact cost of transportation per ton-mile. In fact, there is no accurate basis that could be employed in obtaining such cost. This is because no one has as yet had experience in navigating the new canal, nor has the transportation of commodities on a large scale been undertaken until this year. The actual cost may not be correctly ascertained until the transportation business has been developed.

It was generally understood, however, that the ton-mile cost on the old canal was about two mills. In 1899, the Canal Advisory Committee, of which General Francis V. Greene was chairman, estimated that the cost of transportation, at that date, was 1.75 mills, per ton-mile. The committee estimated also that the cost of transportation on the new canals would be decreased to 0.52 of a mill-ton-mile.

Taking the ton-mile cost on the old canal, as computed by the Greene Advisory Committee (1.75 mills) and considering that the old type canal boats, now being

used on the enlarged canal, may be loaded to a greater draft and carry larger cargoes than was possible when the estimate was made, and further considering that such boats may now move at a greater rate of speed in the larger waterways and make a greater number of trips each season, it would appear that my previous statement that "coal may be profitably transported in large volume via the canal, at a rate of two mills per ton-mile" is susceptible of proof. When, later in the season, business on the canal has developed considerably, figures showing the cost of operation will be compiled and the actual cost, per ton-mile, ascertained.

If the canal system was constructed, owned and operated by a private corporation, undoubtedly, in computing the ton-mile transportation cost, all of the elements mentioned by Mr. Wilkins would be included. In great public improvements undertaken by governments, however, such course has not been followed. Governments enter upon great undertakings for the benefit, direct or indirect, of their citizens, and actual financial returns coming directly to the government are not expected. This is in line with the theory that the general good to be obtained will compensate the nation or state for the actual money expended.

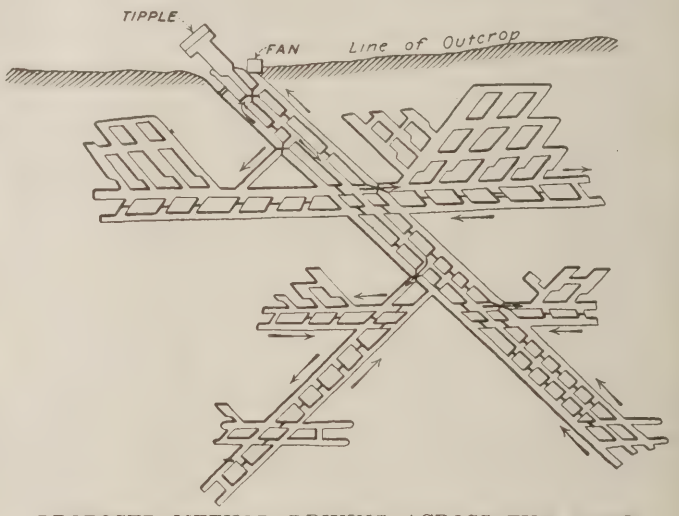
So far as the New York canals are concerned, the securing of a direct revenue by the state is forbidden by constitutional provision, tolls having been abolished about 1881. It is interesting to note, however, that up to the time the tolls were abolished, the state had received a revenue from its canals of approximately $40,000,000, over and above all sums expended up to that time, for construction, maintenance and operation. In addition to this great revenue, it was a fact worthy of note that the canal was the greatest single factor in the growth of the state in both population and commerce. It is fair to assume that, even with the collection of tolls forbidden, as provided by the constitution, the indirect return from the enlarged canal system will continue to be equally as great as was derived from the operation of the old canals.

Canal System of the State Compared with Other Public Utilities

The state maintains a splendid system of state highways, which enables the farmer to bring his products to market cheaply and conveniently. Commodities are transported speedily, from place to place, by trucks. This easy means of transportation has a considerable bearing upon the cost of such commodities to the consumer; and yet, in the computing of the cost to the consumer, it is not the practice to compute also the proportion of taxes paid for highway construction and maintenance to meet sinking-fund contributions and bond-interest charges.

Further, as I understand the policy adopted by the United States Post Office Department, in computing the cost of the postal service, the expenditures for plant, namely, the post-office buildings, are not included. Yet, it is evident that such cost must be met by the taxpayers. To apply the suggestion of Mr. Wilkins, further, in additon to the cost of the stamp required to carry a letter to its destination, we should add the writer's proportion of taxes.

However, as to the canals, their mere existence tends to hold in check and maintain a uniformity of rail rates in the territory between Chicago and New York City. The potential canal competition on the rail-rate structure has an effect that it is impossible to measure in dollars and cents, and every student of transportation knows that, but for the existence of the canals, the rail rates betwen Chicago and New York and the rates made with relation to the Chicago-New York route would be materially higher. In fact, every rate in New York State is affected; and, for every day the improved canal is in operation, the citizens of this state are saving, either directly or indirectly, a large sum in transportation costs. This applies equally also to the merchant, the manufacturer and to the farmer, in the state.



Since it is impossible to reduce the actual figures, the state-wide benefits received from the canal, I am not of the opinion that the construction, maintenance or interest charges should be considered in the computation of ten-mile transportation cost, but the actual boat operating cost alone should be used as the basis.

Albany, N. Y. Supt. of Public Works.

Working 10-Ft. Inclined Seam

Letter No. 4—Kindly permit me to offer the following suggestions, in regard to the working of a 10-ft. seam inclined at an angle of 10 or 15 deg. and having a sandy-shale roof and pavement, the surface being practically level and traversed by numerous streams, as described in the inquiry, *Coal Age*, Mar. 23, p. 561.

Assuming that the seam dips, at the given inclination, from its outcrop on the surface, if the main slope

PROPOSED METHOD DRIVING ACROSS THE PITCH

is driven at right angles to the outcrop line it would mean that the main haulage road would have a grade varying from 17½ to 26½ per cent., the tangent of 10 deg. being 0.176 and that for 15 deg. 0.267.

In order to avoid this steep grade, I would suggest driving the main slope and air-courses at a suitable angle across the pitch, as indicated in the accompanying figure. The cross-entries can then be driven to the right and left of the main road, on the strike of the seam. As shown in the figure, the rooms are then driven to the rise of the cross-entries and at such an angle as to enable the loaded cars to be handled readily from the faces of the rooms to the gangway.

Taking the dip of the seam as 10 deg. from the horizontal, and driving the main slope at an angle of 30 deg. with the strike of the seam, will give a grade of 100 × tan. 10 deg. × sin. 30 deg. = 100 × 0.176 × 0.5 = 8.8 per cent. This arrangement of entries and rooms driven across the pitch will greatly reduce the difficulty in the handling of the cars and facilitate haulage.

There is one consideration that must not be overlooked in the development of this seam. It may be assumed from the fact that the surface is practically level and the seam has the inclination mentioned, it is practically impossible to open the mine from a point that will afford natural drainage. Had it been possible to do this, such a plan should have been adopted instead of driving a slope to the dip, which makes it necessary to provide means for drainage by pumping.

A careful study must be made of the topography of the country, in order to avoid the endless annoyance, cost, delay and possible disaster that will surely follow the extraction of the coal in this seam, without due regard is had to the streams that may find their way into the mine through cracks and crevices extending to the surface.

In the development of the underground workings, entries should not be driven under the streams, except where it is absolutely necessary, and such openings must be supported by masonry or a tried system of timbering, wherever they pass under these waterways. No room or pillar work should be permitted under or in close proximity to a surface stream.

An accurate map should be made showing all the surface features and the workings below. A "dead line" should be drawn on the map showing the nearest permitted approach of the rooms to the surface streams. In determining this dead line, the high-water mark of the stream should be considered and care taken to avoid any natural crevices in the strata that would permit the inflow of water into the mine.

Assuming that the main haulage slope is driven across the pitch, at such an angle as to give an 8.8 per cent. grade, it will reach a depth of nearly 200 ft., about 2000 ft. from the opening. At this depth, less trouble and expense would be experienced in the extraction of the coal. But, a roof of the character described will always prove an important factor in the safe and economical mining of the coal.

Thomas, W. Va. W. H. NOONE.

Strong vs. Weak Stoppings

Letter No. 1—Permit me to offer a few comments on the question of the advisability of building permanent or resistible stoppings, in contrast to the so-called "resistless or destructible stoppings" suggested by the discussion reported in *Coal Age*, Apr. 6, p. 628. The point of interest is to determine what effect each of these two types of stoppings would have upon an explosion that occurred in a mine. This subject has often been discussed but no definite conclusion has yet been reached.

Each type of stopping has its champions and it is true that each possesses certain advantages; but, so far, I have been unable to form any idea of what might be considered a resistible stopping or one that would successfully resist the force of a mine explosion. It is true that many stoppings have remained intact through violent mine explosions; but this, no doubt, was due to the fact that adjacent stoppings of lighter and weaker construction yielded to the pressure, which was then equalized on both sides of the stouter stoppings.

As a matter of fact, the data available on the maximum pressure attained in mine explosions is very limited indeed, since this depends on the intensity of the explosion, which in turn depends on numerous other conditions, including the resistibility of the mine stoppings.

Propagation of an Explosive Wave

When we consider that an explosive wave travels in every direction from its point of origin and that the intensity of the blast and the distance it is propagated depends on the amount of fuel, in the form of inflammable gas or dust, available for the support of the flame, and the amount of oxygen in the ventilating current available for its combustion, it would seem that neither type of stopping as at present constructed and adapted, would have any effect to arrest the progress of an explosion; except only that the lighter stoppings, by yielding, would allow a more ready expansion of the heated gases and thereby reduce the destructive force of the blast, to that extent.

Realizing that coal dust is the principal factor in the propagation of mine explosions, I believe that, by a modification of our stoppings, overcasts and methods of working, and a restricted use of both types of stoppings, together with the adoption of explosion barriers, in the form of wet areas, and the use of stone or rock dust as hereinafter described, mine explosions can be entirely localized so as to produce no effect whatever on other sections of the mine.

Proposed Method of Building Stoppings

Let me commence with the main headings and suggest building good permanent stoppings of concrete, say not less than 12 in. thick and intrenched at least 6 in. in the coal at the sides. Then, at intervals of 400 ft. or thereabouts, build a self-readjusting collapsible stopping. This may be done by swinging vertically from strong top hinges an iron or steel door, which should be hung between good concrete sidewalls and be free to swing in either direction. Overcasts, likewise, should be built with self-readjusting doors in the bottom sidewalls. A little cement or clay may be used to seal them under normal conditions.

Arriving, now, at the room entries, no rooms or working places should be turned off these entries, for a distance of 300 ft. This space should be maintained as an explosion barrier and must be kept thoroughly wet, at all times, shelves of stone or rock dust must be suitably arranged herein. The same applies to all roads, headings and air-courses that may lead into this section. It is not necessary, however, to leave a solid pillar of coal, here, 300 ft. thick; as No. 1 room can be utilized as a heading to turn rooms back toward the main or branch heading, as the case may be. These rooms, however, should not be allowed to cut through

or intersect the main or branch heading, unless it be the last one, which is sometimes essential in gaseous mines to successfully ventilate the panel or workings during or after the process of pillaring. In that case, this last room should also be an explosion barrier and treated accordingly.

On all room headings, I would suggest building nothing but light destructible stoppings that would immediately yield to the explosive force, thus allowing it to spend itself by expanding as much as possible, before coming in contact with the barriers, and thereby reducing to a minimum any chance of flame passing beyond the area where it started. The self-readjusting stoppings and overcasts will probably take care of any excess pressure that would find vent on the main or branch headings, and the force of the explosion will generally dissipate itself in the section where it originated, without doing any material damage to the ventilating system in other portions of the mine.

From what has already been said we can see that to successfully confine or limit explosions, some panel or sectional system of working the mine must be adopted; but this should not prevent ventilating two panels or sections with a single air-split, providing the connection between the two sections was long enough to form an explosion barrier; and providing, also, that this connecting passage contain one or two iron or steel doors suspended in such a manner that they would automatically drop by the force of an explosion and form stoppings that would prevent the inrush of afterdamp into the unaffected workings—thus allowing the workmen time to retreat to the main heading until the ventilation has been rearranged. I advise, however, that where possible each panel or section be arranged large enough to warrant a separate air-split and, incidentally, to assure some financial return for the additional expense incurred by these safety features.

It is very apparent that no matter what happens, the work of rescue after an explosion would be greatly facilitated by such a system of ventilation, as the air current could be restored in a much shorter period than is possible by the present system. The plan should certainly commend itself to our consideration when we remember the large toll of life that afterdamp has been responsible for in past explosions. E. P. BRENNAN.

Thomas, W. Va.

Safety in Shotfiring in Mines

Letter No. 5—It is true, as suggested by R. J. Pickett, *Coal Age*, Apr. 20, p. 754, that we have in our mines both the "enemy alien" and the "German sympathizer," and for this reason it is of the utmost importance that the work of handling explosives be safeguarded in every manner possible.

My opinion is that the employment of shotfirers, in all mines, is the only guarantee of safety at this time, and these must be men who are fully qualified for the position. Their duty should be not only to inspect and fire all holes, but they should charge, tamp and fire every shot themselves. No one but an authorized shotfirer should be permitted to handle the explosives.

We have but to consider, for a moment, the danger to a shotfirer when miners are permitted to charge and tamp their own holes. A miner so disposed could overcharge his hole to a dangerous extent, and this would not be known to the shotfirer, who might be killed by the blast. The overcharge might cause a blownout shot followed by a dust explosion that might wreck the mine and cause the loss of many lives.

Observation shows that the majority of our coal companies are too slack in their regulations regarding the use of explosives. In the majority of cases, the miner draws his powder check or dynamite check from the office, takes it to the magazine, and is given a full keg of powder or as much dynamite as he wishes, which he takes with him into the mine to use in his own way.

Reason should convince any man that this is not a safe manner of handling the work of blasting coal in mines. There should be an absolute check on the amount of explosives taken into the mine each shift, and this amount should not exceed what is required to perform the work in that shift. The number of shots to be fired should be reported when the miners quit work for the day. This will enable the shotfirer to determine the amount of explosives required for his work.

INDIFFERENT WORK OF SHOTFIRERS IN PLACES

While shotfirers are employed in the mine where I am working, the miners charge and tamp their own shots, and each miner splits his fuse so as to expedite the work of firing the shots. The shotfirer goes from place to place as rapidly as possible, and takes no time to look for danger. Although every shotfirer is fully qualified and should inspect each place for gas before firing a shot therein, this is not often done.

The mining laws of Kentucky and many other states require the shotfirer, upon completing his work each shift, to post a notice in a conspicuous place, showing the number of shots fired and the number not fired, specifying the number of the room and entry where such shots were located and giving their reasons for not firing them.

Each shotfirer must also make a daily record, in a book kept for that purpose, showing the number of shots fired, the number failing to explode, and the number of blownout shots, besides the number of holes that, in their judgment, were not properly prepared. This is an important provision and should be made a part of all mining laws.

It is my opinion that if the work of blasting were made to conform with the requirements of the mining laws, in the several states, there would result a great reduction in accidents from this cause. I believe that the firing of shots in mines has an important bearing on the conservation of life, which is so necessary for the winning of the war. OSCAR JONES.

Worley, Ky.

What's Wrong with the Mines?

Letter No. 1—The editorial that appeared in *Coal Age*, Apr. 20, p. 752, asking what is wrong with the mines that there should be an increase of 21 per cent. in the fatalities reported for the year 1917, as compared with those of previous years, set me to thinking and wondering as to the actual underlying cause for this large increase in the number of mine accidents.

While the dangers attending the mining of coal are quite well known to every mining man, in a more or less general way, I have noticed that there is a tendency with many mining men to treat with almost absolute contempt the greatest dangers. This must arise, I believe, from an ignorance of the real significance of such dangers.

A large majority of accidents can only be avoided by the constant watchfulness and mutual coöperation of every person employed in and around the mines. As a chain is no stronger than its weakest link, so likewise a mine is no safer than the acts of the most careless worker therein would determine.

All coal-mining states have laws regulating the operation of their mines with respect to safety, prescribing what should be done to avoid accidents and prohibiting practices that are considered unsafe. If these laws were strictly enforced by the persons charged with that duty, and if mine workers would coöperate to that extent, there would be a great reduction in the number of accidents that occur each year in the mines.

A word about the timbering of working places: Most state laws provide for some form of systematic timbering at the working face, and it is the duty of every miner to set the timbers as quickly as the required distance is reached. Instead of this, however, the average miner is prone to start first loading his coal, intending to set the needed timbers as soon as this work is finished.

When a mine official, entering a man's place, finds him loading coal and the timbers not set, it is plainly his duty to insist on the work of timbering being done without further delay. He should remain and see that his orders are obeyed. The man should then be warned, and, if found guilty of a second offense, he should be prosecuted.

If this was done, men would soon come to realize that it would be better for them, to obey the law. The leniency of mine officials, in this respect, goes far toward increasing the accident list, as miners are not slow to take advantage of this leniency and defer the setting of timber until their coal is loaded and the place cleaned up ready for a new start.

Accidents That Should Be Avoided

Frequent accidents occur on haulage roads, due to drivers failing to sprag their cars, instead, bracing their backs against the front of the car in an attempt to hold it back from the mule when a single slip of the man's footing may cause his death or serious injury. Tripriders take many chances jumping on and off fast-moving trips, and miners violate the mine rules by riding loaded trips and discarding the traveling road that has been provided solely for their safety. Doors on main haulage roads, bad tracks, and cars left standing on the tracks are the causes of many avoidable accidents in haulage. These all show bad management on the part of mine officials and lack of coöperation on the part of employees.

Regarding the most serious accidents, due to explosions of gas and dust, three elements are to be considered: (1) Accumulation of gas; (2) accumulation of dust; (3) means of ignition of the gas or dust. Let me say that the accumulation of gas must be avoided by an ample ventilating current conducted so as to sweep all working faces and void places in the mine. The accumulation of dust is more difficult to prevent; but the evil may be greatly reduced by loading out all fine coal and the "bug dust" produced in machine mining, and by enforcing strict regulations in regard to the blasting of the coal. All roads and other passageways should be cleaned regularly and watered as may be required to lay the dust and prevent its suspension in the air current.

The use of steam jets on the intake to moisten the air current, and different devices for spraying the cars of coal as they pass out of the mine only partially eliminate the danger from the presence of dust. Rock-dust zones and barriers suspended from the roof in entries serve only to arrest an explosion when one is started. Any system of watering to lessen the dust danger effectively must moisten the dust with, at least, 50 per cent. of its weight of water, as determined by the Belgian Royal Commission on the inflammability of coal dust.

Calcium-Chloride Treatment of Dust

Some years ago I witnessed the experiment of sprinkling, by hand, finely powdered calcium chloride on the walls, roof and floor of a haulage road 1500 ft. in length, in a mine in Lancashire, England. One application was good for three weeks and had the effect of extracting sufficient moisture from the air to make the fine dust so that it could be molded in the hand, and was caked on the floor where men were walking to and fro.

About 1 lb. of calcium chloride was used for every 60 sq.ft. of surface. It was thought that the amount of moisture the calcium chloride extracted from the air, however, was a drawback to the rest of the mine. In my opinion, a mixture of one part of calcium chloride to two parts of rock salt ground to a fine powder is most effective for neutralizing the coal-dust danger, while a plentiful supply of water thoroughly mixed with the dust is next.

Finally, to eliminate the many causes of ignition of gas and dust, allow me to suggest the exclusive use of electric head lamps. Also, no one should be permitted to carry a safety lamp except a duly authorized mine official. Every man entering the mine should be carefully searched for tobacco, pipes and matches. All shots should be fired by competent shotfirers, after the men have left the mine, and only permissible explosives should be used.

Men should not be allowed to work in a place where the lamp shows more than a ½-in. gas cap. Chemical fire extinguishers should be kept at all shaft and slope bottoms and in pump rooms and other places where they may be needed. A trained fire-fighting force should always be available and telephone connection with the surface should be maintained throughout the mine. Fire drills should be carried out regularly once a month.

In conclusion, I would say that the most that is wrong in the mines of today is their lack of system in mine management and the lack of coöperation of mine workers.

Cumberland, B. C., Canada. James Touhey.

INQUIRIES OF GENERAL INTEREST

The Law on Ventilation

In the discussion of matters of general interest in mining, at our regular weekly safety meetings, important questions have often arisen that we have been unable to thrash out. Two of these that were discussed recently pertain to provisions of the bituminous mine law of Pennsylvania relating to ventilation, and we would be glad to see them discussed by readers of *Coal Age*. They are as follows:

1. In Art. 9, sec. 3, the law specifies that the distance between crosscuts in room pillars shall not be more than 35 yd. nor less than 16 yd.; but nothing is said, in that section, in regard to the distance between crosscuts in entry pillars. However, in Art. 6, sec. 4, relating to intake and return entries, the law specifies that said entries "shall not be driven more than 200 ft. beyond the last cut-through, except for exploratory purposes."

The meaning of the law, as would appear from these two references, seems to be that crosscuts in entry pillars can be 200 ft. apart, while those in room pillars cannot exceed 35 yd. or 105 ft. It is needless to say that some good mining men dispute this interpretation of the law, and we shall be interested in hearing what *Coal Age* readers think.

2. The first two sections of Art. 9 specify clearly the amount of air required by law to be circulated in the mine, for each person employed therein; also, the number of men permitted to work on a single split of air. The law reads (sec. 1), in part, as follows:

> The return air, from each split where from 70 to 90 persons are employed, shall be conducted by an overcast or an undercast into the return airway, which shall lead to the main outlet. The ventilation shall be conducted through the main entries and cross-entries to the working faces of all working places in the mine, in sufficient quantity to dilute, carry off and render harmless the smoke and the noxious and dangerous gases generated therein, to such an extent that all working places and traveling roads shall be in a safe and healthy condition for the persons working and traveling therein.

The question has arisen, What, in the meaning of the law, constitutes a return airway, and what are the limitations that require an air current charged with noxious gases to be conducted directly into the return airway leading out of the mine?

To illustrate, suppose there are two pairs of entries, working rooms and ventilated by the same air current, and the first pair, on this split, reports gas in dangerous quantity. Does that circumstance make the rest of the split circulating through the second pair of entries "return air" in the meaning of the law?

Or, again, suppose the air current passes over a gob section generating noxious gases, the said section lying between two live entries, all being ventilated by the same air-split; would this current become "return air," immediately after passing over or through the gob section, and would it be practical to work the rooms on the return side of such a gob section?

Believing that the practical discussion of these questions will be of value to every mining man, they are submitted to *Coal Age*, hoping for their publication.

CHARLES MARTIN, Superintendent,
Smokeless, Penn. Conemaugh Smokeless Coal Co.

Replying to the first question asked by this correspondent, it may be stated that, while the Pennsylvania Bituminous Mine Law permits entries, in the mines of that region, to be driven 200 ft. ahead of the last crosscut, it is not customary to do this, except where special appliances are employed to conduct the air current forward to the face of each heading.

In some cases, where the mine is generating no gas, advantage is taken of this feature of the mine law to reduce the expense for driving crosscuts. In such cases, however, use is made of flexoid tubing, or a canvas brattice is erected in the headings to conduct the air forward to the face.

Regarding the second question, the law clearly specifies that the ventilation shall be conducted to each working face in such a manner that the place shall be safe and healthy for work. This provision would make it unlawful to work men where the air current was charged with gas to a dangerous extent or where the place was unhealthy by reason of being located on the return side of a gob section. The arrangement suggested by correspondent would often limit the number of men employed on a single air-split to less than the 70 persons ordinarily allowed. We hope to hear from others on these important questions.

Track Switch Calculations

Kindly explain the meaning of the "frog number," in mine trackwork, and show how to calculate the length of the "lead rail" of a switch. FOREMAN.
———, W. Va.

In all trackwork, frogs are numbered 1, 2, 3, etc., corresponding to the ratio of the length of the frog rails to their spread. Thus, a No. 4 frog has a spread of 1 ft. in 4 ft. The calculation of the length of the lead rail of a switch is based on the number of frog used and the gage of the track.

Assuming a 3-ft. track gage and a No. 4 frog, the length (l) of lead rail, in feet, required is found by multiplying twice the track gage (g), in feet, by the frog number (n), which gives, in this case:

$$l = 2gn = 2 \times 3 \times 4 = 24 \text{ ft.}$$

The radius of curvature (R), in feet, is then found by multiplying the length of lead rail by the frog number;

$$R = nl = 4 \times 24 = 96 \text{ ft.}$$

These formulas and rules have been fully explained sometime since, in *Coal Age*, Vol. 10, p. 653.

EXAMINATION QUESTIONS

Miscellaneous Questions

(Answered by Request)

Ques.—If 31,983 cu.ft. of air and marsh gas was passing through a section of the mine where the lamp flame indicates that the mixture is at the highest explosive point, what is the quantity of gas given off?

Ans.—A mixture of pure marsh gas and air, at its most explosive point, contains 9.46 per cent. of gas. The volume of gas, in this case therefore, is 31,983 × 0.0946 = 3025 cu.ft. per min.

Ques.—What quantity of air will pass in each of the three following splits: A, 6 x 6 ft., 1000 ft. long; B, 6 x 5 ft., 2000 ft. long; C, 6 x 4 ft., 3000 ft. long; the original airway being 6 x 5 ft., in sectional area, 5000 ft. long, and producing 80,000 cu.ft. of air per min., the pressure being constant?

Ans.—This question, as it reads, appears to be wholly unintelligible. It is not clear what is meant by the original airway 6 x 5 ft., 5000 ft. long. The combined length of the three splits given is 6000 ft., and each of these airways has a different cross-section. It might be assumed that the question intended to ask, What quantity of air would be circulated in the three splits named, under the same pressure that would circulate 80,000 cu.ft. of air per min. in an airway 6 x 5 ft., 5000 ft. long.

However, the pressure that would produce this circulation in a single airway of the dimensions given is practically 510 lb. per sq.ft., which would give a water gage of 100 in. nearly. The velocity of the air current would be 80,000 ÷ 30 = 2666 ft. per min. It is hardly to be supposed that this can be the meaning, therefore it will be necessary to revise the reading of the question before a solution can be given. Such a question has the appearance of being a catch question.

Ques.—The water in a mine is hauled up a shaft 400 yd. deep, in two tanks each holding 400 gal., the one ascending and the other descending. What horsepower is the engine developing when delivering a tank of water every 3 min. at the surface, not including the time lost in emptying and filling the tanks?

Ans.—The depth of this shaft is 400 × 3 = 1200 ft. Assuming that the tanks balance each other and that the weight of the rope acting alternately to increase and decrease the load on the engine may be ignored, and taking the time of making each hoist as 3 min., the effective horsepower of the engine, disregarding friction, is

$$H = \frac{400 \times 8\frac{1}{3} \times 1200}{3 \times 33{,}000} = 40.4\ hp.$$

Ques.—In a certain shaft the cage weighs 2½ tons, empty car, ¾ tons, loaded car, 2½ tons, rope, 2 tons; what should be the small diameter of a conical drum whose large diameter is 28 ft., in order to equalize the load on the engine?

Ans.—In this case, the weight of the cage and car is $W_c = 2\frac{1}{2} + \frac{3}{4} = 3\frac{1}{4}$; weight of material hoisted, $W_m = 2\frac{1}{2} - \frac{3}{4} = 1\frac{3}{4}$; weight of rope, $W_r = 2$ tons. The ratio of the small diameter (d) to the large diameter (D) of a conical drum, in order to equalize the load on the engine, is given by the formula,

$$\frac{d}{D} = \frac{2W_c + W_m}{2(W_c + W_r) + W_m}$$

Then, substituting the given values in this formula, we have for the small diameter of the drum, the large diameter being 28 ft.,

$$d = 28\,\frac{2 \times 3\frac{1}{4} + 1\frac{3}{4}}{2(3\frac{1}{4} + 2) + 1\frac{3}{4}} = 18\tfrac{9}{17}\ ft.,\ \text{or, say}\ 18\ ft.\ 10\tfrac{1}{4}\ in.$$

Ques.—What precautions would you suggest to protect workmen while retimbering a shaft for safety?

Ans.—The work of retimbering a shaft should start at the top and proceed downward, in order that the men shall always be working beneath that portion of the shaft that has been made secure with new timbers. On the other hand, if this work were to be started at the bottom and proceed upward, the men would constantly be in danger of loose material falling upon them from the weakened timbers in the shaft that are to be replaced.

Not more than one or two sets of timbers should be removed at one time, and these should be replaced with new timbers before more sets are removed. Only experienced men should be employed in this work, and the utmost care must be taken in supporting the platform on which the men stand while performing the work. Every precaution must be taken to prevent material falling down the shaft while the work is in progress.

Ques.—A borehole A strikes the coal at a depth of 60 yd.; another, B, reaches the same seam at a depth of 70 yd.; and a third, C, at 80 yd. The hole, B, lies 600 yd. north 30 deg. east from A, and the hole, C, 600 yd. south 30 deg. east from D. Find the direction of (a) a level course in the seam; (b) the direction of the dip; (c) the rate of dip in this seam.

Ans.—The lines joining these three holes form the sides of an equilateral triangle, the length of each line being 600 yd. Since the bearing of the line AB is N.30°E, and BC is S.30°E, the line AC is due east. Assuming a level surface. the seam falls 10 yd. from A to B and 10 yd. from B to C. The fall from A to C is 20 yd., and halfway from A to C the seam will have fallen 10 yd. and have the same elevation as at B, or 70 yd. below the surface.

(a) A level course, or the strike of the seam, therefore, is a line drawn from B to halfway between A and C, and its direction is north and south.

(b) The direction of the dip is at right angles to the strike or due east.

(c) The line AC lies in the full dip of the seam and the rate of dip is 20 yd. in 600 yd., or 1 in 30.

COAL AND COKE NEWS

Harrisburg, Penn.

Seward E. Button, chief of the Department of Mines, has called attention of the United States authorities to the conditions brought about in the coal regions of Pennsylvania by drafting of miners at a time when there is a call for the greatest possible production. He has requested that some arrangement be made which will permit more miners to remain at work.

A statement issued by Mr. Button says that he is "very much concerned over the acute conditions that exist at present in the great mining regions of the Commonwealth owing to the imperative demands of the Federal Government for a maximum production of coal in the face of a constantly decreasing force of mine workers whose ranks are being seriously depleted by the drafting of men into the army." Undoubtedly the present demands upon the operators are the most exacting ever known, but it is the universal desire of the mine owners to give to the Government the greatest aid and support. The desire of the operators, however, is made impossible of fulfillment by reason of the shortage of employees. There has been a constant drain upon certain classes of employees, particularly drivers, runners and electricians, and the result has been to reduce greatly the force necessary to produce the best results in mining coal.

The Public Service Commission on May 27 issued an order on the New York Central Lines to make reparation to the New York and Pennsylvania Co., Lock Haven, of $9245.29, as rebate for overcharges for movement of coal from Munson and Hawk River districts to Bald Eagle Junction. The order is the result of litigation before the commission in which it was claimed that the charges were too high. The sum covers claims in the year ending Aug. 24, last.

Culm piles, though they have been classed as personal property, do not present a case of an ordinary chattel, says Judge Strauss (Luzerne) in his opinion continuing the preliminary injunction brought by C. P. Holden against George J. Llewellyn and Frank Carlucci, restraining the latter from carrying off a culm pile in Pittston township containing between 160,000 and 190,000 tons of coal.

This suit was rather complicated as both plaintiff and defendant claimed title to the property and actual possession, and while the plaintiff produced proofs that he acquired the coal in the pile, subject to royalties, the defendants held that an injunction did not apply and that the plaintiff should have recourse to the law courts.

Fairmont, W. Va.

West Virginia coal men are so well pleased with the proceedings at the annual meeting of the National Coal Association that there is little doubt that the first meeting of the executive committee of the West Virginia Coal Association, the state organization, will be harmonious and highly profitable. The meeting was originally set for June 1, but owing to the meeting of the National Coal Association, the holiday which followed and other matters, the meeting at Huntington was postponed until June 21. The various local associations have elected their representative on the executive board and it now remains for the board to get together and outline a policy. It was at first intended to have the associations vote as units in the state organization, but this may be changed in accordance with the action of the National Coal Association giving each corporation belonging to the local coal associations a vote in the state body as they now have in the national body. W. H. Cunningham, of Huntington, who still retains the secretaryship of the association under the old organization, has announced that the postponed meeting will consider war work as well as actual coal matters.

There were 184 candidates at the recent mine examination held in Fairmont, and the class of men aspiring to be mine foremen, firebosses, etc., was commented upon by W. J. Heatherman, the new mine inspector for West Virginia, and the district mine inspectors, who were here. The interest in the examination was high and the class was the largest yet reported excepting that at Charleston, where there were 230 entries.

The work of organization of the coal miners in the Fairmont district is moving along rapidly. The contract agreement plan of the Consolidation has not proved very successful, and in most places the organization perfected is that of the United Mine Workers. "Mother" Jones is in the region and is making speeches at various points. There are six or eight other organizers in the field. There has been nothing said which could be objected to by operators as far as is known.

Birmingham, Ala.

That the campaign launched some weeks ago to increase production at mines has not been in vain is shown by the greatly improved conditions noted in every section. Coal production for the week shows a most favorable improvement over the output of the last few weeks. However, in some localities it is still maintained that with the labor available the output should have been on a larger scale than that recorded.

Extreme effort is being made to bring labor in the mining district up to a full realization of the absolute need of a maximum production of coal. A special plea has been addressed to the coal miners of this district by the Alabama Fuel Board to give every day possible to mining, and the request is meeting with almost general response.

A movement is on foot to educate the miner to the comforts of life in providing better homes and a means to spend money. It is hoped that through this medium the miners will feel the desire to earn more and will not cease operations, or lag in their work, as soon as their immediate needs have been satisfied.

Backing this effort is the attempt to arouse the patriotic spirit of the men. Speakers from the war-stricken countries are making tours of the mining sections and are telling the employees that every day given to the work of coal production means that much toward winning the war.

Charleston, W. Va.

For the week ending May 25 an increase in the production of coal was achieved in the Kanawha district amounting to about 16,000 tons, the production figures for the week ending May 18 being 137,852 and for the week ending May 25 154,634. The 154,634 tons were produced during 3862 working hours. Owing to car shortage 825 hours were lost, the loss in time owing to labor shortage being only 245 hours, to a strike 40 hours, to mine disability 479 hours. Failure of the power companies in this section to furnish an adequate supply of power was principally responsible for the loss of time included in mine disability, although a wreck caused a half-day's loss. Up to May 28 a total of 31,807 cars were loaded out of the Kanawha district, as against 31,638 empties received. The car quota for the Kanawha district has been reduced in terms of tons to the amount of 1820 tons per week and in the New River field by 2300 tons per week.

Reports from Raleigh and New River fields show that the mines have been experiencing a good deal of difficulty in securing power, mines in the Raleigh field or rather in certain parts of the Raleigh field having been shut down on the 27th and 28th because of lack of power. The mines in the New River field were also handicapped by the same cause, and operators in the New River district are almost up in arms, the power failure coming just at a time when conditions were beginning to become satisfactory and conducive to a greater production.

West Virginia fared well at the recent meeting of the National Coal Association. Jere H. Wheelwright, president of the Consolidation Coal Co. was elected president; C. H. Jenkins, president of the Central West Virginia Coal Operators' Association, Quinn Morton, of Charleston, and J. J. Tierney, of McDowell, were named as directors, and the last three, together with R. H. Gross, of the New River Co. with headquarters at Boston, and T. B. Davis, of the Island Creek Coal Co. with headquarters at New York, were elected directors at large.

Attorney General E. T. England of this state having ruled that women may be employed in work around and outside of West Virginia mines, several mines with headquarters in Huntington are considering the feasibility of employing women at the picking tables, on the tipples and on work of a similar nature.

PENNSYLVANIA

Anthracite

Hazleton—The Dodson Coal Co. has acquired 3300 acres of bituminous coal lands on the Maryland-West Virginia boundary line. The company will develop the holdings at once.

Hauto—The Harwood Coal Co., J. S. Wentz & Co. and the Harleigh-Brookwood Coal Co. are the first in the anthracite field to agree to contribute to the war chest fund in proportion to the amount donated by their men. It is expected that all of the mining corporations will contribute sums equal to the total of their employees.

Duryea—The patriotic spirit was ablaze on May 30 among the workers at the William A colliery of the Lehigh Valley Coal Co. The occasion was the raising of two flags on a fine new steel flagpole 75 ft. in height, which was erected during the week in the center of a grass plot in the colliery yard. One of the flags was an American banner purchased by the employees of the colliery, the other being a Liberty Loan honor flag, presented to the colliery by the Old Forge bank, in recognition of the colliery having achieved a 100 per cent. record in subscriptions to the third Liberty Loan.

Freeland—Charging that the defendant company is about to remove $2000 worth of steel rails from an abandoned mine without authority or right, Charles H. Hemsath has brought a suit in equity against the Harleigh-Brookwood Coal Co. and W. G. Thomas, and has been granted a preliminary injunction by the court. The Hemsath heirs contended that at the time the coal company abandoned the property the leasing company was in arrears about $1500 in royalties and wants this amount from the company before the rails can be taken away.

Barry—The first electric washery ever installed in this state, which will enable six men to recover 500 tons of fuel a day, will be put in operation about June 15, by the Schuylkill Coal Co. The coal company has leased the riparian rights along the Mahanoy Creek for a distance of four miles for a period of 20 years. It is estimated there are 3,000,000 tons of steam and domestic sizes in the tract. On the property in question the company has dredged down 14 ft. without running through the deposit. Decision to utilize electric power for the operation of the washery grew out of the costly experience suffered by steam washeries in the loss of boilers through the heavy percentage of lime and sulphur in the water. The saving in labor (the project requiring only six men) compared with 12 or 14 with steam plants, was also a factor. Power for the washery will be furnished by the Eastern Pennsylvania Railways Co., at Pottsville.

Plymouth—The fire that broke out in the Red Ash vein of Nottingham No. 15 colliery, Lehigh & Wilkes-Barre Coal Co., early in April continues to burn notwithstanding the heroic effort of officials and company hands to extinguish it. During the weeks it has existed much good work has been accomplished, however, and it is now thought the worst is past and in a brief space of time it will be surrounded and quenched which when done will enable the company to increase the output of this famous old mine, one of the largest in the hard-coal regions and one where fatalities and serious accidents are a rarity notwithstanding its heavy daily tonnage.

One or two fires exist in other collieries of this company beyond the river, but from last reports all was going well and they also will soon be overcome.

The last mine fire of any consequence in this section was in Buttonwood colliery when operated by the Parrish Coal Co., and that of the Avondale colliery, D. L. & W. R.R. Co. in September, 1904.

Shamokin—In its program to speed up anthracite production the Susquehanna Collieries Co. is replacing veteran foremen with younger men at the same time taking care of the older men. Recent changes made include transfer of David Hughes, foreman at Pennsylvania colliery, to Richards No. 4, Hughes having been succeeded at Pennsylvania by Michael Farrell, foreman at Hickory Ridge. Ray Hughes, a mining engineer, has been made assistant foreman at the Scott colliery.

Rockville—The Mt. Jessup colliery was shut down by William Potter, Federal fuel administrator for Pennsylvania, on June 3, for loading dirty coal. Thirty-nine cars from this operation were condemned last week. F. H. Ford, general manager of the company, has been ordered before Mr. Potter and will be told there must be a change at his plant and that reports must be made to the county administrator daily.

Bituminous

Connellsville—The tipple at the Kyle mine of the H. C. Frick Coke Co. was destroyed by fire, entailing a heavy loss and the temporary shutdown of the mine. The fire is thought to have been caused by a spark from one of the dinkey locomotives.

Perryopolis—The Alfred Fuller estate, consisting of 510 acres of coal land, has been sold to the Jamison Coal and Coke Co., of Greensburg, for a consideration of $1,760,000, or at the rate of $3200 per acre. This price is considered the highest price ever paid for undeveloped coal land in Fayette County. It fronts on the Pittsburgh and Lake Erie R.R. and the Washington Run Railroad.

Pittsburgh—Director John J. McKelvey of the Department of Charities recently was authorized by the Council's finance committee to open and operate a municipal coal mine at May View. An appropriation of $80,000 already has been made by Council for opening a municipal mine. The bill authorizing Director McKelvey to proceed was amended to provide for employment of a mine superintendent at a salary not to exceed $300 per month.

Philadelphia—James M. Orr, of Clarksburg, W. Va., president of the Orr Coal Mining Co. with offices here, was fined $5000 by Judge Dickinson in United States District Court on May 31 for profiteering in coal. The prosecution was the first in this district. Mr. Orr charged a price for bituminous coal higher than that fixed by President Wilson. The coal was billed to customers at the regular price, but by a secret understanding an excess was collected. Mr. Orr plead guilty, and the Government was satisfied with the imposition of a fine.

Uniontown—Mine Inspector Richard Maize, chairman of the board of examiners for the Fifth Bituminous District, has announced the following as having passed a successful examination: Ralph Miller, of Dunbar, and Elmer Mathews, of Mount Braddock, mine foremen; Herbert Pratt, of Connellsville, assistant mine foreman; George W. Landman, of Dunbar, George Foley, Smith R. Matthews, Thomas Callihan and Arthur Whitlock, all of Mount Braddock, firebosses.

The Whyel Coal Co. of this city has sold 27 tracts of coal land in Harrison and Marion Counties, West Virginia, to John Y. Hite, of Fairmont, W. Va., for $585,000.

ALABAMA

Fairfield—The Tennessee Coal, Iron and Railroad Co. will construct an addition to the Koppers byproduct coke ovens at this place, consisting of two additional batteries of 77 ovens each, or a total of 154 ovens, together with complete byproduct recovery plants. The additional ovens are being constructed at this time to secure the toluol, ammonia and benzol, which is needed for the manufacture of ammunition and also to secure a saving of several hundred thousand tons of coal per annum, which will result by substituting coke manufactured by the byproduct oven process for coke which is now being manufactured in beehive ovens

WEST VIRGINIA

Glen White—The E. E. White Coal Co. has decided to erect a $150,000 steel coal tipple, with a daily capacity of 5000 tons.

Downs—The Rachel Gas Coal Co. will resume full working time shortly, having installed new electrical equipment following the recent fire which handicapped the plant for several days.

Eccles—The mines at this place will hereafter be supplied with cars from both the Chesapeake & Ohio and Virginian railways, as was formerly the custom until a misunderstanding of the orders of the regional director shut off the supply from one of the roads.

Clarksburg—Daniel Howard has purchased two mining plants of the Consolidation company, acquiring control of Mines No. 39 and 46 at Two Lick Station. Mr. Howard is one of the leading operators of the Clarksburg field and this purchase increases the magnitude of his holdings, giving added capacity of something like 1000 tons a day.

Clarksburg—For a consideration of $67,500 the Fairmont and Clarksburg Fuel Co.'s mining plant in this county has been purchased by J. H. Henderson, of Connellsville, Penn., according to a deed filed for record recently in the county clerk's office here. The property, which includes traces of the Pittsburgh and Keystone bed of coal, is routed on the West Virginia & Pittsburgh branch of the Baltimore & Ohio R.R. along McKinney's Run.

Weirton—At a cost of approximately $600,000 a byproduct coke plant and 600-ton blast furnace will be erected across from Steubenville at this city. The plant will be erected near the Phillips Sheet and Tin Plate Co.'s works and will be operated under Government supervision. The contract, which has been awarded to a Cleveland concern, calls for the completion of the plant shortly after the beginning of next year. The plant will afford employment for 500 men and is said to be the first of a number of steel plants to be erected in the Steubenville district in the near future.

Morgantown—J. W. Heatherman, Chief of the West Virginia Department of Mines, has announced that he will hold an examination for mine foremen and firebosses at Morgantown on July 26 and 27. When the details of the Short Course in Coal Mining, which is to be given at West Virginia University from June 17 to July 27, were brought to Mr. Heatherman's attention he was enthusiastic in his praise of the work the university is doing for the miners, and said he felt that the men who took the short course should have an immediate opportunity to take the examination for their mine foremen's and firebosses' certificates. Inasmuch as the short course is given without cost to all who are interested, it is a splendid opportunity for those who are preparing for the examinations, or for those who failed at the May and June examinations and desire to make another attempt to secure their certificates. Prof. A. C. Callen, Morgantown, will be glad to hear from any who are planning to take the Short Course in Coal Mining.

Charleston—An agreement between 90 per cent. of the members of the Central West Virginia Coal Operators' Association and the miners' organization of the district has been accepted by the association. By it the miners and operators bind themselves to produce as much coal as possible during the war, and the agreement brings the two organizations into closer alliance. It is believed that the rest of the operators will unanimously stand by the agreement.

Gross negligence is charged against the mine officials and officials of the state department of mines by Coroner P. S. Shirkey in his verdict on the inquest he conducted in the cases of the 13 miners who met their deaths in the recent disaster in the mine of the Mill Creek Cannel Mining Co. The coroner found that the 13 miners who lost their lives came to their deaths from suffocation and holds the mine and department officials equally responsible through negligence in making proper inspection of the mines.

INDIANA

Petersburg—New mines are being opened by the Atlas Co., just north of here. Seven machines will be used in the new mines and employment will be given to a large force, it is announced.

Frankfort—The supply of coal at the municipal light plant was exhausted, and railroad shops, munition plants and other important industries dependent upon this supply of power have been seriously handicapped. Robert Bracken, fuel administrator for Clinton County, asked immediate relief for this plant. It seems that the city plant at Frankfort has been obtaining a special grade of coal from mines at Panama, Ill., and special machinery had been installed to handle this coal. Under the zoning system, which went into effect Apr. 1, Illinois coal could not be supplied this plant and its machinery would not permit the use of Indiana coal. The case has been referred to the national Fuel Administration at Washington.

Evansville—The Gibson-Moore Coal Co. mine, located between Howell and Evansville, has been closed down. It is not expected the mine will be opened again as it is said it could no longer be operated at a profit. The mine is one of the oldest in the city and for many years was operated by Capt. John Ingle.

On May 22 practically all the coal mines along the Evansville & Indianapolis R. R. resumed operation after many of them had been idle for eight weeks. A dispute over freight rates caused the shutdown of the mines, and this dispute was settled recently by the Government. It is estimated that the resumption of work by these mines will mean an increase of about 25,000 tons of coal a week in Indiana. About 1000 miners are employed at the mines that were closed down.

ILLINOIS

Alton—A river terminal, equipped with loading apparatus, has been completed here and will be used for transferring coal from cars on track to Government barges for delivery to up-river points as far as St. Paul.

Galesburg—A new coal shaft is being sunk at Soperville by Lloyd Pople. The shaft is down 65 ft. and will be sunk 70 ft. more. A good vein of coal is expected at a depth of 135 ft. The mine will be prepared to hoist coal this summer.

Danville—The Big Four R. R. (Cairo division) is storing coal at Lyons for next winter. The company has laid extra track and has extra men to care for the coal. It is estimated that 50,000 tons will be stored at Lyons. The coal comes from the Ledford district, south of Harrisburg, Ill., and is low in sulphur, which fact will reduce the possibility of fire from internal heating. Another precaution is the storing of only lump coal, all other kinds being taken to different points on the road for immediate consumption.

Edwardsville—William P. Early has purchased 80 acres of land near this city for $40,000, the purchase being, it is said, for the Donk Brothers Coal and Coke Co., of St. Louis. Prior to this purchase of top ground necessary for sinking a shaft, Early had bought 10,000 acres of coal rights in the vicinity of Edwardsville, the rights being, it is believed, for the Donk interests. One new shaft will be sunk in June and will be in operation before winter. Later two mines will be sunk and eventually the entire field will be opened. The Donk interests own large mines at Maryville, Troy and Collinsville, as well as the St. Louis, Troy & Eastern R. R. which takes coal products into St. Louis.

Nokomis—The fire which started May 18 in the North Mine of the former Peabody Coal Co., near here, and was thought last week to be under control, gained renewed headway early last week and did a great deal of additional damage. Many heavy falls of slate and coal occurred and concrete props and reinforcements were destroyed. Some of the entries, it is feared, have been damaged beyond repair. The falls have added to the difficulties of the fire-fighters. The state mine rescue car and workers have remained constantly at the mine and although the heat and smoke have made it necessary for the men to work in 15-min. shifts, only one person has been overcome. The latest report is that the flames are again under control and that the mine will not have to be sealed. The damage is so great, however, that it will probably not be possible to work the mine for some time.

KENTUCKY

Carrollton—Business men of Carrollton, Ky., and stockholders of the Beattyville Coal Co., of Beattyville, Ky., operating a coal mine, have formed a new coal company to operate as the Jett Coal Co., which will be largely a transportation and jobbing organization. The new company plans to transport coal by water from the Beattyville mines down the Kentucky and Ohio Rivers to market. The steamer "Sea Lion" and nine barges have been purchased, and the company plans the purchase of another steamer and additional barges at once. The officers of the new company are Col. J. S. Jett, of Carrollton, president; George W. Calhoun, director; John Jetter and Capt. Elisha Woods, directors of transportation. Shipments will begin at once.

Foreign News

Montreal, Que.—On May 24 a fire which broke out at the George Hall coal yards, Wellington Basin, caused damage to the amount of $100,000. About 10,000 tons of coal were destroyed.

Edmonton, Alta.—Duncan McDonald, district inspector of mines in the Drumheller district, has been appointed Fuel Inspector of Alberta with authority to inspect all coal shipped and with special reference to the coal consigned to Manitoba. Care is to be taken that all coal sent to Manitoba shall be of the best grade.

Cairo, Egypt—The fuel problem in Egypt, which at one time threatened to cause the most serious hardship to the whole coun-

try, has been largely solved, says the annual report of the government's financial adviser, Sir William Brunyate, by the development of the Red Sea oil fields and the adaptation of machinery to produce gas distilled from vegetable refuse. The report declared that an "adequate supply of oil for all purposes" should shortly be available. The Hurghdada oil field, for example, although only discovered in 1914, is now yielding 15,000 tons a month.

Edmonton, Alta.—Large increases are shown in the amount of coal mined and exported from Alberta during the first three months of the year, as compared with the corresponding period of 1917. The total amount of lignite coal mined in January, February and March, 1918, was 810,972 tons, as compared with 744,700. The production of bituminous was 712,313 tons as compared with 650,319, and the anthracite output was 39,409 tons as compared with 37,817 in the first three months of last year. The amount of coal exported to Manitoba during the three-months period was as follows: Lignite, 98,195 tons; bituminous, 9958 tons, and anthracite, 602 tons, the increase over the three-months period of 1917 being 66 per cent.

Personals

James Harlor has been appointed general inside foreman of the Spring Mountain operations of the Lehigh Valley Coal Co., at Jeanesville, Penn., succeeding William F. Hamer, deceased.

John Gordon Smythe, chief engineer of all divisions of the Consolidation Coal Co., has been appointed a captain in the officers' reserve corps and will probably be assigned to construction work.

Halver Halverson, formerly mine foreman of the Lucerne mine No. 1 of the Rochester & Pittsburgh Coal and Iron Co. at Homer City, Penn., has been made superintendent of the Luciusboro mines of the Brush Creek Coal Mining Co. at Waterman, Pennsylvania.

Thomas Wendling, of Shamokin, Penn., inventor of many breaker, hoisting and coal-cleaning mechanisms, superintendent at the Bear Valley colliery, has been appointed outside district superintendent of the Pottsville district of the Philadelphia & Reading Coal and Iron Co.

Thomas A. Furniss, mine inspector for the twelfth bituminous district of Pennsylvania, with headquarters at Punxsutawney, has resigned his position. He will become general manager of the new company which will reopen the Onondaga shaft near here. Mr. Furniss, together with Donner Steel Co. interests of Buffalo, N. Y., will compose the new company.

W. M. Downer, superintendent of the Ernest mines of the Jefferson and Clearfield Coal and Iron Co., at Ernest, Penn., has been made general superintendent of the Coal Run Mining Co. and the Tide Coal Mining Co. with headquarters at Indiana, Penn. Mr. Downer will be succeeded at Ernest by Mr. Davis, formerly superintendent of the Luciusboro mines of the Brush Creek Coal Mining Co. at Waterman, Pennsylvania.

J. W. Bell has resigned as superintendent of the Marvel coal-mining operations of the Roden Coal Co. and has accepted the position of general superintendent of coal mines for the Gulf States Steel Co., with headquarters in Birmingham, Ala. Mr. Bell received his training in the coal mines of Scotland and holds a certificate of efficiency from the British Government. He was also at one time chief mine inspector for West Virginia. The scope of his work in the new position will be much enlarged.

Industrial News

Greenville, Ky.—The Beech Creek Coal Co. has filed notice of an increase in its capital from $150,000 to $400,000, to provide for expansion.

Clendenin, W. Va.—The Elk Gas Coal Co., with an authorized capital of $50,000, has been organized by E. W. Smoot, of this city and his associates.

Sergent, Ky.—The Whitley-Elkhorn Coal Co. is considering plans for the immediate installation of electrical equipment for the operation of its mines.

Barbourville, Ky.—T. C. Gilliam, president, and Oscar Jackson, secretary, of the Emanual Blue Gem Coal Co., have filed notice of the dissolution of that company.

New York, N. Y.—Burns Brothers have acquired property adjoining their coal pockets on the Boulevard, Long Island City, about 92 x 123 ft., to be used, it is said, for extensions.

Pikeville, Ky.—Rodgers Brothers Coal Co. has filed notice of an increase in its capital from $75,000 to $100,000, to provide for the proposed improvements in its plant on Shelby Creek.

Lexington, Ky.—The Elkhorn Coal Co. has filed notice of an increase in its capital from $100,000 to $600,000. The company is considering plans for extensive improvements at its properties.

Constable Hook, N. J.—The United States Government, Bureau of Yards and Docks, Navy Department, has had plans prepared for the erection of a large local coaling plant to cost approximately $130,000.

Jersey City, N. J.—Plans have recently been filed by the Central Railroad of New Jersey for the erection of two new coal-thawing plants at its pier No. 18, to cost about $188,000. Contract for the structures has been awarded.

Toledo, Ohio—Mackenzie & Schroyer, Inc., the Ajax Coal Co. and the Marquette Mining Co. announce that they have removed their offices from 1313-1314 Second National Bank Building, Toledo, Ohio, to 507 Union Building, Cleveland, Ohio.

Dorton, Ky.—The Kentucky-Elkhorn By-product Coal Co., of Shelbiana, has been organized with a capital of $50,000 and is planning for the immediate development of a large tract of local coal lands recently acquired. H. L. Cox heads the company.

Sebree, Ky.—The stockholders of the Belcourt Coal and Mining Co., Inc., at a meeting at Belcourt, in western Kentucky, on Apr. 13, decided to dissolve the corporation, and at a later meeting on May 25, officially dissolved. R. N. Carlisle is treasurer of the company.

Chattanooga, Tenn.—A big company capitalized at $1,000,000 was recently incorporated here as the Marion Coal and Lumber Co., by Herbert E. Lettes, C. L. Remtinger and Clement M. Egner. The company proposes development of coal and timber properties.

Madisonville, Ky.—In order to enlarge its operations and make several improvements in its plant, the Circle City Coal Co. has increased its capital stock from $50,000 to $100,000. R. H. Gruschow is president, and has associated with him Frank Fehr and Forest Richardson.

Elkhorn City, Ky.—The Middle Ridge Coal Co. has been organized, and is planning for the immediate development of property recently acquired at Middle Ridge. Millard Burk is president; A. J. Younce is vice president, and G. H. Francisco, secretary and treasurer, all of Pikeville, Ky.

Christiansburg, Va.—The Anthracite Coal Corporation recently incorporated, is planning for immediate development work on its tract of 2500 acres. The company plans for an output of about 300 tons for initial operations, to be increased ultimately to 1000 tons daily. C. C. Mathey, Galena, Ill., is president and manager.

Johnstown, Penn.—To take care of its rapidly expanding business, the Flood City Manufacturing Co., which manufactures section insulators and electrical supplies for use in coal mines, has leased a suite of offices in the Swank Building, Johnstown, Penn. All executive business and sales will be conducted from the new quarters.

Charleston, W. Va.—With the completion of the extension of the Coal River branch of the Chesapeake & Ohio from Seth to Whitesville, further development of mining operations is expected. A river grade will be provided from Dorothy to St. Albans, when the extension is ready for operations, cutting off a mountain grade and tunnel haul.

Louisville, Ky.—Two hundred men employed in the barge-building plant of the West Kentucky Coal Co. and the Paducah Marine Ways Co., at Paducah, Ky., went on strike on May 29, asking for an increase of 10c. an hour in wages, or from 55 to 65c. an hour. The West Kentucky Coal Co. ships considerable western Kentucky coal south by the Ohio and Mississippi, and for several years has operated its own barge-building plant.

St. Louis, Mo.—The Snow Coal Co. has been organized here by Clifford M. Snow, for several years past connected with the Consolidated Coal Co. Mr. Snow is one of the best-known coal men in the southern and western states and he has for many years past been connected with the larger mining interests in the Middle West. It is understood that he has also taken over the Liberty Coal and Supply Co.'s business, as L. C. Meid, manager of that company, has been drafted.

Cincinnati, Ohio—The Reliance Coal Co., one of the largest dealers in Cincinnati, has leased the yards on the river front formerly operated by the Marmet company, giving the Reliance an additional storage capacity of about 50,000 tons, which will be devoted largely to river coal. Additional equipment for the handling of coal at the yard will be installed at once, in order to enable the company to use the entire space, 350 x 400 ft., for the accumulation of a large supply of winter fuel.

Louisville, Ky.—The Sullivan Pond Creek Co., of Stone, Ky., lately incorporated with capital of $500,000 to develop coal properties in Kentucky, is planning big developments on 4000 acres of land and will shortly purchase equipment. Offices are at Tralee, W. Va. Officers are J. C. Sullivan, president; J. J. Morrison, vice president; J. B. Frank, secretary; L. R. Taylor, general superintendent; D. M. Goode, Williamson, W. Va., constructing engineer; W. E. Holloway, Cleveland, consulting engineer.

Toledo, Ohio—Activity prevailed at the Toledo loading docks during the past week, showing an increased movement of lake coal. The lake trade is fairly under way and the vessel movement is brisk. The Toledo & Ohio Central docks during the week ending May 31 loaded 68,000 tons, which was exactly the same tonnage loaded the previous week. The total handled since the opening of the season is 334,000 tons. The Hocking Valley docks during the week ending June 1 loaded 126,841 tons as compared with 125,596 tons the previous week, making a total since the opening of the season of 619,736 tons.

Buffalo, N. Y.—The Donner Union Coke Co. lately began the work of reopening the old Onondaga mine of the Buffalo & Susquehanna Coal & Coke Co. in the Punxsutawney district, and is now engaged in building a big by-product coke plant on upper Buffalo river in this city, convenient to both rail and water transportation. About 2000 tons of coal a day will be used. Nearly a year will be needed to get the coke plant ready, but the mine will go into operation in two months or so. Till needed for coke making the coal will be sold. Both plants will be run in the interest of the Buffalo Union Furnace and the Donner Steel Co., the former controlled by Harry Yates and the latter by W. H. Donner

Columbus, Ohio—An important change in the operation of coal trains in Ohio has been ordered by the Director General of Railroads. In previous lake seasons when the movement of West Virginia coal to the lakes was heavy much of the Chesapeake & Ohio and the Norfolk & Western coal was transferred at Columbus from those roads to the Sandusky Division of the Pennsylvania, and shipped to the port of Sandusky for the Northwest. But with a large amount of that coal going to the Atlantic seaboard the Sandusky line has not been carrying the usual tonnage. In order to equalize matters it has been ordered that coal trains originating on the Toledo & Ohio Central on both sides of Armitage be shipped over the Hocking Valley to Columbus and there transferred to the Pennsylvania for shipment to the lakes at Sandusky. This relieves the Toledo & Ohio Central lines and it is thus more able to take care of shipments from the mines directly on its own line. The rule provides that K. & L. trains be dispatched to the lakes over the Pennsylvania.

Peoria, Ill.—The Illinois Mining Institute has closed its session at the Jefferson Hotel in Peoria. Among the addresses at various sessions of the convention was one by Charles B. Scott, general manager of the National Safety Council, on "Accident Prevention." Other speakers on the program were C. W. Chappelle, of the Ironton Engine Co. of St. Louis, on "Advantages of Storage-Battery Locomotives in Mines"; Joseph C. Thompson, state mine inspector, on "Permissible Explosives"; Frank Farrington, president of the Illinois Miners' Union, who spoke on the patriotic side of the miner's work; A. J. Moorshead, president of the Madison Coal Corporation; E. A. Holbrook, of the Federal Bureau of Mines, and Senator John Dailey, of Peoria. Mr. Moorshead, one of the largest mine operators in the state, emphasized the need of better working conditions in the mines of the state and called attention to the need for greater coöperation, especially during war times, between mine operators and mine workers. A banquet and trips of inspection through various industries of Peoria were other features of the institute.

MARKET DEPARTMENT

Weekly Review

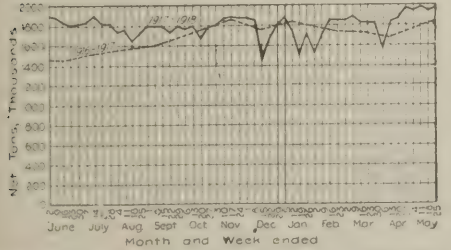
Soft Coal Production Reaches New High Mark—Anthracite Shipments Decrease—Anthracite Allotment Program Announced—Labor Question Serious—Non-Preferred Industries to Receive Little Coal—No Stocks in Dealers' Yards—Lake Shipments Falling Short

DURING the week ending May 25 the production of bituminous coal reached a new high level with a total output of 11,811,000 short tons, approximately 100,000 tons more than was produced in the preceding week. Anthracite coal shipments for the week ending May 25 amounted to 40,752 cars, a slight falling off as compared with forwardings during the week ending May 18. Telegraphic advices regarding production for the week ending June 1 indicate that there will be a sharp decline in output for that week, due to the observance of Memorial Day.

Every effort is being made to increase the output at the mines, though several factors tend to keep production from reaching the maximum. In Iowa mines were closed down during the week of May 18 for lack of orders. The same is true of mines in other Middle Western and Western states. In Alabama the miners continue averse to working regularly.

An interesting feature of the week was the announcement by the Federal Anthracite Committee on Distribution of the long-awaited allotment program. It is estimated by the committee that anthracite production during the present coal year, which will end on March 31, 1919, will total 89,000,000 long tons. Of this amount it is expected that 54,345,783 long tons will be available for domestic consumption, which is 5 per cent. more than was distributed for domestic purposes during the last coal year. The remaining 34,654,217 gross tons represents the quantity consumed at the mines, by industries, and by the railroads. New England is to receive 10,331,000 gross tons of anthracite, which is 1,497,621 gross tons more than was used in that section last year. Canada, on the other hand, will receive only 3,602,000 gross tons of hard coal this year, as against 3,856,021 tons last year. Reductions will also be made in the quantity shipped to the Middle West and the Northwest. No anthracite coal will be sent west of the Mississippi or south of the Potomac and Ohio Rivers.

Of course, it is one thing to make allotments and quite a different matter to produce the coal. The anthracite industry has lost 32,000 men since the United States entered the war—by draft, by enlistment, and by enticing wages in other industries—and now finds itself in a serious situation. Settle the labor question for the hard-coal operators and the problem of a sufficient supply of anthracite to meet all demands would be simplified.



The matter of fuel priorities is being decided rapidly. No attempt is being made to disguise the fact that many non-preferred industries will fail to get coal this winter. There will not be coal enough to go around. However, systematic distribution will eliminate the uncertainties of last winter, and it is expected that domestic consumers and the preferred industries will get the coal they need.

Dealers in the chief cities on the Atlantic seaboard are far behind on deliveries of anthracite, though they report bituminous in fair supply. In the Middle West there exists a heavy demand for prepared coal, the sluggish market on fine coal having caused many operators to take on orders for mine-run to the detriment of those depending on them for lump, egg and nut coal. St. Louis reports an unusually quiet market on steam sizes, with no railroad buying to mention. Elsewhere both steam and domestic demands are insistent.

Shipments of coal by lake routes are falling short of the figures planned by the shippers. The movement in May is calculated to have been under 1,000,000 tons a week. Larger shipments are necessary if the Northwest is to have its requirements supplied before winter.

COAL PRODUCTION

Production of bituminous coal during the week ended May 25 equaled and even slightly exceeded the record week of May 11. The output of soft coal (including lignite and coal made into coke) during the week ended May 25 is estimated at 11,811,000 net tons, an increase of approximately 100,000 net tons over the production of the preceding week. The average

production per working day is estimated at 1,968,000 net tons as against 1,952,000 net tons during the week previous and 1,829,000 net tons in May, 1917. Beehive coke production during the week ended May 25 is estimated at 664,000 net tons, a decrease compared with the week of the 18th of 14,000 net tons, or 2 per cent. The average daily production is estimated at 111,000 net tons, a decrease of 2000 net tons compared with the preceding week.

Byproduct Coke—Production of byproduct coke declined slightly during the week ended May 25 due to shortage of labor in Maryland and greater shortage of labor in Pennsylvania. The ratio of production to maximum capacity for the first time since Apr. 20, fell below the 89 per cent. mark, the production during the week of the 25th being equivalent to 88.5 per cent. of maximum capacity as against 89.2 per cent. during the week preceding. Out of total losses of capacity of 11.5 per cent., 2.6 per cent. was attributed to lack of byproduct coal as against 2.8 per cent. during the week of May 18; 2.6 per cent. was due to labor shortage as compared with 2 per cent.; 4.9 per cent. to repairs to plants as against 5.3 per cent.; 0.2 per cent. to "no market" as compared with 0.3 per cent., and losses due to all other causes rose from 0.4 per cent. during the week of the 18th to 1.2 per cent.

Shortage of coal continues to be the factor limiting production in Indiana and New Jersey, although in the latter state slight improvement was reported during the week of May 25. Labor shortage in Maryland reduced the ratio of production to full-time capacity from 100 per cent. during the week of May 18 to 86.2 per cent. In Pennsylvania losses due to labor shortage rose from 10.7 per cent. during the week of May 18 to 13 per cent. during the week of the 25th. Repairs to plants caused production in Kentucky and New York to decline, while in Alabama losses due thereto were considerably less than during the preceding week. "No market" losses in Minnesota declined from 9.6 per cent. to 7.6 per cent. during the week of May 25.

CARLOADS OF COAL AND COKE ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended May 4	May 11	May 18	May 25
Bituminous shipments, 123 roads	202,558	207,145	205,026*	207,349†
Anthracite shipments, 9 roads	40,570	38,767	41,011*	40,752†

*Revised from last report. †Subject to revision.

Anthracite shipments fell slightly during the week of May 25, amounting to 40,752 cars against 41,011 during the week of May 18.

BUSINESS OPINIONS

American Wool and Cotton Reporter—On account of uncertainty in the wool supply, in available machinery and in other conditions, no good basis can be made for planning a season's distribution of woolen and worsted goods. It is not the total supply of wool which is causing anxiety, but rather the fact that some of the mills operating upon Government contracts are becoming short in supply, and it is feared that unless the situation clears up rapidly there may be a certain amount of machinery idle. There is nothing to justify some of the prices which have been asked. In cotton goods the situation has become somewhat stronger during the week under review mainly because the shortage of goods is becoming greater and buyers seem more willing to pay somewhat higher prices.

Dry Goods Economist—The plan for the coördination of the Government's interests with those of the various branches of the textile industry, announced on May 28,

makes clearer than ever the scarcity, present and prospective, of woolen and other fabrics as a result of the Government's requirements. The selling agents of woolen and worsted dress goods manufacturing concerns state that from 50 to 60 per cent. of their looms are running on Government orders and that the remainder, in so far as there is labor to operate them, are available for the production of goods for civilian use. Deliveries of woolen fabrics by manufacturers are of a hand-to-mouth character, but whatever is delivered is a welcome addition to the stock of the merchant who is lucky enough to get it. The linen shortage is as acute as ever.

Bradstreet's—Further expansion in war activities, ascending wages, excellent crop prospects, greater repression in purely civilian outputs, and widespread complaints of scarcity of goods and scarcity of men, stand out as the more prominent developments of the week. Willingness to buy, as distinguished from ability to get staple commodities, creates an air of activity, but the situation in this regard evidences fears of a famine in goods rather than real present necessity, and merchants in parts of the country are requesting that shipments of products scheduled for fall delivery be hastened.

Marshall Field & Co.—Wholesale distribution of dry goods for the current week shows a pronounced increase over shipments for the corresponding week of 1917. Road sales for both immediate and future delivery are larger than they were the same period last year. Customers have attended market in arger numbers. Collections are very satisfactory, showing a considerable increase over those of the same week a year ago.

The Iron Age—Some days may yet elapse before a balance can be struck between the definitely scheduled demands the Government will make upon the steel industry in the remainder of the year and the country's newly ascertained capacity in the various finished forms required. The committee is still hard at work both in Washington and New York. New reports are brought out of Government plans for laying hold of steel works. The industry continues skeptical as to all such news, but is in no mood to do business except at Government call. The demand for skilled labor for munition plants, shipyards and other vital industries is rapidly increasing, but men are not in sight. Plans are on foot for systematically making heavy drafts through regional committees, upon workers whose ordinary employment is gone or will be because material is withheld.

Atlantic Seaboard

BOSTON

Diminished receipts of railroad fuel a feature. Large number of mills operating on small margins of supply. No more "free" coal from the provinces for the present. All-rail receipts fall off; at tidewater the volume is short of making up the deficiency all-rail. Economies are resorted to in every direction and more and more buyers turn to steam sizes as an expedient. Other than decisions of Priority Board there is no guide for distribution; clear statement of policy much needed. District representatives, except on direct instructions from Washington, are apparently not ordering coal forward to preferred requirements in New England unless contracts are on file. Baltimore & Ohio territory rumored practically cut off all-rail from destinations this side of New York piers. Anthracite trade interested in allotment but not optimistic.

Bituminous—There are fewer cases of tangible distress among steam users than was thought probable for the period June 1 to 15. Somehow the industries manage to keep going, although very likely in the extreme anxiety to get fuel for future needs there has been enough duplication of requisitions to make the situation not quite so close to the danger line as previous estimates seemed to show. In many of the large manufacturing centers there are so many avenues of supply that it is difficult to gage receipts at individual plants with any degree of accuracy. The railroads themselves, for their own supply, frequently find certain of their storage depots almost down to bare boards on short notice, requirements and receipts will vary so from day to day. This is notably true today when all-rail receipts show a heavy reduction in tonnage of engine fuel due to complications over purchases and instructions from Washington to postpone commitments. It is also true that the railroads are suffering from the new attitude of the Fuel Administration in ordering coal to such preferred requirements as steamship bunkers and by-product plants. A year ago most of the New England roads had from three to four times as much reserve as they have today. At Boston, arrivals of water coal are being drawn against for considerable tonnages to supply the local needs of the Boston & Maine. While not in arrears to the same extent, the other roads are often finding themselves in a position where they have to lift coal off the ground instead of taking it from current receipts either by rail or by water.

Many important utilities and industrial plants are in virtually the same predicament. Even those who rely upon rehandlers with large storage facilities are not able to get deliveries on contracts and appeal to the fuel authorities for assistance. Coal is usually forthcoming on such procedure if the plant is of preferred importance, but usually the "help" is at the expense of some other preferred user who is forced into the same difficulty a few days later. No remedial measures seem to be in sight, and buyers are utterly at loss how to proceed to get coal. Such "contracts" as they have made are only 40 to 60 per cent. productive, and the fact is plain that only by doubling up on their requisitions both all-rail and at tidewater, together with other expedients, are they able to keep in operation on slender stocks.

The 100,000 tons of Dominion coal arranged for at Sydney, C. B., to load the lake-built steamers now coming into the coastwise service is all that can be had from this source for the present. The coal having been tried and found desirable by several of the large buyers, the Shipping Board has already been urged to arrange further deliveries. It is understood, however, that the first lot was furnished under such special circumstances that no additional shipments are looked for, at least for the present.

The volume of bituminous received through the great gateways continues to show a serious shortage as compared with a year ago. May showed an average movement of 470 cars per day commercial bituminous, a drop of 80 cars, or 14½ per cent. from the 1917 total for the same month. Railroad fuel showed a drop of 312 cars, or 76 per cent., the average movement of cars passing the gateways daily for this purpose being only 98 as against 410 a year ago.

Tidewater receipts are not any more encouraging except from Hampton Roads, and the latter fall far short of making up the shortage all-rail. Available figures covering Hampton Roads dumpings for New England during May show 983,136 net tons, a gain of 192,038 tons over May, 1917.

The total net loss for May, therefore, is 530,308 net tons, an alarming figure when all estimates were based on heavy gains during the summer months. All this is an argument against zoning of consuming territory as between rail and water delivery, except possibly Maine, where the elimination of all-rail delivery would probably work no great hardship. For the rest of New England, the best opinion inclines to the present distribution unrestricted as to destination whether from the gateways or from tidewater ports. The fact that the nearly 10,000,000 tons received all-rail last year went to make up deficiencies by water should be reason enough for allowing coal this year to run to points adjacent to tidewater, unless there should be a material increase in water-borne coal. At this writing, no sufficient increase is in prospect.

At Hampton Roads the balance between ships and coal has been maintained until within a few days, when once more there is beginning to be a surplus of ships over coal. This excess of bottom is sure to increase the next few weeks for three reasons: the number of new vessels in the service, the number coming out of repair yards, and recent orders of the fuel authorities, directing the flow of coal west rather than to tidewater. At this writing, there is a good chance that submarine activities early this week will materially reduce the number of arrivals at the piers.

The conservation department of the Fuel Administration is busy urging economies in the different steam users, the latter having naturally, of their own initiative, made headway in the same direction. Much attention is being given patent stoking, even by relatively small manufacturers, and there have been some interesting results, particularly with respect to anthracite steam sizes. One mill using 3500 to 4000 tons weekly is able to use three parts birdseye or barley to four parts bituminous, and grades of the latter that were never suspected of working satisfactorily in such combination have been used to excellent result. The demands for washed rice and barley have therefore increased by leaps and bounds, and the prudent buyers are those who are taking liberal shipments now, while the going is good.

Anthracite—Receipts neither all-rail nor at tidewater have as yet shown the expected increase. At tidewater the difficulty is still with barges and towing power, particularly for destinations around Cape Cod. It will probably be several weeks before New England feels the result of restricting domestic sizes from the Middle West and from the South Atlantic States. If there are not barges enough to move what is now reaching the piers at Philadelphia it is hard to see how this movement can be increased materially.

All-rail figures for May show a daily average of 454 cars domestic sizes through the five gateways. In net tons this means 634,005 compared with 556,089 tons in May, 1917. The average daily number of cars of anthracite steam sizes during May, 1918, was 168, or 27 per cent. of the total anthracite receipts at the gateways. This was a somewhat increased proportion of domestic sizes, in itself a favorable sign.

Mr. Storrow has offered to get a certain number of deep-sea barges transferred from bituminous trade should that prove necessary. Developments the next fortnight will bear watching, in the interest of New England.

NEW YORK

Demand for anthracite domestic sizes continues strong, with supplies below requirements. Dumpings at the local tidewater docks show increase over preceding week. Line trade wants coal. Settlement of railroad fuel question results in better car supply, but tidewater stocks are low.

Anthracite—Demand for the domestic sizes continues to be far in excess of the supply, and dealers who are fortunate enough to have good connections have so far been unable to stock any considerable amount in anticipation of next winter's orders. Many of the smaller dealers are still unable to secure sufficient of the larger sizes to take care of their trade, and for that reason the bins are practically empty.

With the Government report for the week ended May 25 showing a decrease of 259 cars shipped than were shipped during the preceding week, dumpings at the New York tidewater piers for the week ended June 3 show 6542 cars, as against 6205 cars the preceding 7 days, an increase of 337 cars. This city did not, however, receive all of this tonnage, much of it being sent by water to Long Island Sound points and into New England.

Further conferences have been held by the local authorities and coal men with a view of providing for the storing of 300,000 tons of coal to be sold to the poor next winter but so far nothing of a conclusive nature has resulted. The principal subject of discussion is to find a place where the coal can be stored. Other conferences are to be held.

Conditions appear to grow more serious. Supplies are not keeping pace with the demand, and the most optimistic of the trade confess to seeing a lack of coal next winter unless further curtailments and restrictions are ordered and more coal is sent to this market.

Dealers are interested in the statement of the Anthracite Committee of the Fuel Administration showing the distribution of anthracite for New York State for the year 1918-1919 to be fixed at 15,855,300 tons, as compared with 14,169,809 tons for the year 1916-1917, an increase of 11.89 per cent.

The line trade is as active as the trade in this city. Dealers are practically in the same position. They are short of coal and their books are filled with orders.

The anthracite steam sizes are moving freely. Buckwheat No. 1 is scarce except in the cheaper grades. Rice and barley are not in over-supply. While some of the cheaper grades of barley were quoted during the week at $4 f.o.b., the better grades were held at $5.25 f.o.b. with rice at $1 higher.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual
Broken	$6.55	$7.30
Egg	6.05	6.80
Stove	6.30	7.05
Chestnut	6.40	7.15
Pea	4.90	5.65
Buck	4.45@5.15	4.80@5.50
Rice	3.90@4.10	3.80@4.50
Barley	3.40@3.65	3.00@4.00
Boiler	3.65@3.90	.....

Bituminous—The situation shows comparatively no change from last week. Supplies of commercial coal are scarce, except to regular customers, and there is practically no free coal in the harbor. Bunker fuel is in better supply.

The result of the settlement of the railroad-fuel question is already being felt. Cars are in better supply, but the labor situation is such that some operators find it difficult to load all the cars assigned to their openings.

The U-boat ravages along the coast early this week, which resulted in at least the sinking of one coal-laden schooner bound for New England, with nearly 2000 tons on board, will no doubt result in fewer shipments between the Southern ports and the New England States, and a heavier drainage on the New York tidewater market. Heavier insurance rates is one of the direct results of the raids. It is also expected that a reduction in shipments from the Southern ports, will cause consumers in those states to expect larger tonnages from central Pennsylvania.

Producers and shippers are having some trouble to choose between the essential and nonessential industries as indicated by the Fuel Administration. In many instances the consumer is referred to Washington for a ruling.

The dumpings at the New York tidewater piers for the week ended June 3 totaled 6393 cars as against 6285 cars for the previous week, while the Government statistics show that during the week ended May 25, 207,349 cars were shipped to market as against 205,026 cars for the week ended May 18, an increase of 2123 cars.

PHILADELPHIA

Anthracite allotment increased. Mine labor supply slowly decreasing. Doubt as to last year's tonnage being equaled. New England gets preference. New freight rates effective soon. Dealers behind on deliveries. New yard owners to get fuel. Bituminous conditions much improved. Car supply growing satisfactory. Price reduction of 10c. causes little comment.

Anthracite—The most interesting feature of the week was the announcement by the Federal Anthracite Committee on Distribution of the anxiously awaited hard-coal allotments. When the dealers learned through the daily press that Pennsylvania's quota was to be increased by 18.25 per cent. most of them at once clamored for recognition in its distribution. Many seemed to think they were to receive this percentage of increase over their last year's tonnage and were congratulating their shippers and themselves. At this time there is no satisfactory information available to the retail men. The first shock of disappointment came when the sales agents told all inquirers that the increase is over the tonnage of the basic year 1916-17 and that it has not yet been decided into what territories of the state the excess coal will be applied. Unquestionably Philadelphia will need much of it and make an urgent appeal for a large proportion. As a matter of fact word is reported to have come from the office of the local administrator that he is trying to secure 25 per cent. of the added tonnage for the city. It is understood that this increased allotment is made possible by shutting off shipments to the states which are expected to depend upon native soft-coal mines. Yet one important fact seems to have been entirely overlooked, and that is with an increase of 18¼ per cent. over 1916-17 the tonnage will barely equal the amount of coal that came to this market in the past year.

Early in the week the shippers who have been consigning coal to New England received positive instructions to ship into that territory during June one-twelfth of its yearly quota as originally planned plus 50 per cent., or actually one-eighth of its entire year's tonnage in June. These instructions are startling and have greatly upset the dealers here. At the offices of at least two of the largest shippers the local trade is cautioned not to plan for heavy shipments this month and the New England order is being given as the reason. It is beginning to look, too, as if this order will not be effective for one month alone, but may continue for some time; and if continued would give New England its entire supply in eight months. In order to assist the movement via tide to that territory the Government has been assigning barges and also has given heavy orders for new equipment, some being of the new concrete type.

It has been a hard week for the trade here. Some of the heaviest buyers have no stock to speak of and they are being harassed by their customers as never before this spring. Many families planning to leave the city are demanding coal before they close their homes, and also, on account of the advance in freight rates, effective on June 25, practically every buyer wants his coal before the new prices, which will be made to cover the latest freight advance, are announced. There is some speculation as to the recent freight advance, as to whether it will be in addition to the 15c. per ton advance which has been effective but a few weeks. Up to this time the 15c. increase has not affected this city, but outlying points have now been paying it for the past two weeks or more.

On account of the light deliveries recently it will be impossible for the dealers to deliver more than a small proportion of the orders on hand. Yet the fuel authorities continue to advise "promptness in ordering and patience in delivery." The public long ago responded substantially in placing their orders, but it fails to realize that deliveries must necessarily be spread over a period of not only weeks, but months. This week we talked with a number of dealers who are refusing to book any additional business, except from old customers, who for various reasons have delayed placing their orders. They are so hopelessly behind that they fear their inability to furnish even their best trade with more than two-thirds of their requirements. The local administrator continues to cut down on orders as sent to him by the retailers. These reductions as made by Mr. Lewis are seldom substantial but are sufficient to show that his office is scrutinizing every order.

An unpleasant tangle affecting several dealers here has just been straightened out by a ruling covering yards which have been sold or dealers who have commenced business since 1916 and therefore are not covered by the 1916-17 basis. They are to receive a "reasonable" tonnage from the producers or distributors, who furnished the yards previously in business, although as to the very few entirely new yards no exact instructions have been issued other than that they are to receive coal.

Buyers of coal by the carload who for some weeks past have been able to secure their coal supply as usual, except that it had to be hauled by the retailer, experienced something of a jolt this week, when the fuel authorities intimated that they were about to shut down upon the practice. It will be recalled that the National Administration ruled against the practice, but allowed the various state administrators to introduce any modifications they saw fit.

The prices per gross ton f.o.b., cars for line shipments and f.o.b Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.05	Buckwheat	$3.15	$3.75
Egg	4.50	5.70	Rice	2.65	3.65
Stove	4.75	6.05	Boiler	2.45	3.55
Nut	4.85	6.10	Barley	2.15	2.40
Pea	3.45	4.35			

Bituminous—The bituminous trade is experiencing the best conditions that have existed for months. As has been reported in this column for a period of six weeks past there had been a gradual increase in the tonnage of coal received in this market. Therefore the most gratifying feature of the present situation is that the improvement has been a gradual growth, which indicates permanence, at least for the summer. The car supply has jumped upward, especially in the Central Pennsylvania district. As a matter of fact one large operator in that region states he actually had more cars allotted to him this week than he could load. It has been some time since the bituminous trade has been so optimistic. Of course, the demand for coal is still tremendous and many plants claim they are not getting their full requirements, yet the storage stocks are continuously increasing.

The fact that the Government administrative organizations in the settlement of the railway-fuel price controversy reduced the price 10c. a ton, did not produce a ripple of comment in the trade. Inasmuch as the car supply gives promise of continuing in good volume the shippers are satisfied. They are also particularly gratified at the statement of C. H. Markham, the newly appointed director of railroads for the Allegheny region, who said that as 80 per cent. of the coal in the United States was mined in his territory it was to be his special duty to see that the greatest possible transportation efficiency be obtained

BALTIMORE

Plentiful supply of bituminous due to diversions. Anthracite receipts light. "Coal Week" is abandoned.

Bituminous—A careful inquiry in the trade here shows that coal is flowing into Baltimore in liberal quantities. Not only is there a good supply at tide, where a fuel administration order stopped the rerouting of all coal to line points in and near the city and required all to be dumped over the piers, but enough is coming through on all-rail direct consignment to ease off any other immediate fuel emergency. In some cases, particularly in connection with waterfront factories that have profited by the non-diversion order for coal after reaching the Maryland administrator at tide, there has been the first substantial move toward stocking up for the future. The liberal supply of coal here for business use is due almost entirely to the diversion of coal at the Cumberland gateway. The Railroad and Fuel Administrations are now working hard to prevent congestion through allowing loaded coal cars to be piled up on sidings at northern railroad connection points, and when there is the slightest evidence of a jam the coal is rerouted to this city and other points where it can get through without interruption of traffic. It is this coal that has placed Baltimore in most favorable supply situation for the time being.

Baltimore jobbers are looking with interest to a move to be made following the National Jobbers' Convention in Buffalo for a possible revision of the schedule of profit margin. The executive committee of the jobbers held a conference in Washington recently with Cyrus Garnsey, of Dr. Garfield's force, and it was urged that the margin of profit to jobbers was so small that some were in danger of being forced out. The Fuel Administration has acknowledged the important part being played by the jobbers and is said to be desirous of holding them in effective service. To this end jobbers all over the country have been preparing statements from cost sheets, etc., to prove that a revision is necessary. Revisions granted operators and retailers have encouraged the jobbers to hope for similar concessions when the justice of their claim is shown by facts.

Anthracite—The receipts here of hard coal remain below the normal, while the demand has undoubtedly increased. At the present time there are orders on the books of the retailers here for probably nearly 400,000 tons of hard coal for domestic use. Since Apr. 1 the trade has delivered about 125,000 tons, part of which was drawn from their small yard supplies, so that there probably remains less than 7000 tons in dealers' yards here at present as a reserve. The receipts of anthracite here in April were 67,128 tons, and in May fell back to less than 55,000 tons. The normal receipts for May should have been around 65,000 to 70,000 tons. Baltimore's needs are now figured to be 20 per cent. in advance of former years, due to the fact that bins of dealers and consumers were swept clear before this spring came and due to natural growth of the city and war-plant growth. The result is that a deficit is being built up here for next winter. In view of the short supplies the abandonment of a coal order week here was hailed with delight by the retail dealers. It was pointed out that they could not deliver the two-thirds of their present orders this summer unless deliveries were speeded up, and that the 10 per cent. increase in anthracite allowed by the Anthracite Committee of the Fuel Administration, a total of some 93,000 tons, even if diverted to Baltimore in full would fall some 80,000 tons short of the amount estimated as needed here by the Maryland Fuel Administrator.

Lake Markets

PITTSBURGH

Coal movement quite unsatisfactory, permitting much less stocking than is desired. Advanced freight rates. Lake movement proceeding smoothly.

There is almost universal complaint as to the volume of coal movement, both from the Pittsburgh district proper and from the Connellsville region. It is only in rare instances that there is not enough coal delivered for current operations, but the excess shipments are altogether too small to permit coal to be stocked at the rate that should prevail now to insure full operations through the winter. Naturally little hope can be entertained that coal can be moved at anything like as good a rate as in the summer, hence it is imperative that large reserves should be accumulated both for steaming and heating purposes and for byproduct coking.

The present situation is regarded as particularly unfortunate in view of the advance in freight rates that is to become effective June 25, as coal consumers would like to move a maximum tonnage before the rate advance goes into effect. The advances are 15c. when the present rate is 49c. or less per net ton 20c. on rates 50 to 99c., 30c. on $1 to $1.99, 40c. on $2 to $2.99 and 50c. on higher rates. Generally speaking, the 15c. advance will apply on shipments from the Pittsburgh district proper to consuming points in the Pittsburgh district, also from Pan Handle points to Steubenville. The 20c. advance will apply from the Pittsburgh district to the valleys and lake shipping ports, and from the Upper Connellsville to the valleys, while the 30c. advance will apply on Pittsburgh district to Toledo and Cleveland and from the lower Connellsville to Youngstown. Averaging the tonnages used in byproduct coking, the advance on Pittsburgh

district coal will average somewhat over 20c. and on Connellsville coal the average will run about 30c. The new rate to Youngstown, where there is very large consumption in steel mills for power and producer gas generation, as well as for by-product coking, will be $1.05 from the Pittsburgh district, $1.15 from the Upper Connellsville and $1.30 from the lower Connellsville.

There is a better movement in the retail trade owing to efforts of the Fuel Administration to induce retail dealers and their customers to stock up against the winter. Lake shipments are moving with considerable freedom and no congestion has resulted thus far. Returns from blast furnaces showing their ore requirements for the season indicate that somewhat more than 60,000,000 tons of ore should be brought down the lakes this season, against early estimates of 55,000,000 tons. There will be ample vessel capacity for all the coal that is to be moved, the neck of the bottle being the railroads that serve the Lake Erie docks.

The market remains quotable at the 10c. reduction effective Saturday morning, May 25: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district.

BUFFALO

Bituminous in good supply. Anthracite supply normal. Lake shipments up to average.

Bituminous.—Canada is not calling for much bituminous except in secluded districts. Some sections are over-supplied and refuse to buy in any quantity. Buffalo has plenty, and the state generally is fairly well supplied. Here and there come reports that certain consumers are stocking up, but as a rule they are buying as they need it. They do not appear to take much stock in the reports of winter shortage, even after the experiences they have had.

Jobbers are not finding much business to do. The operators and the consumers are getting closer together, as is usually the case when coal is not plenty. The prices of bituminous will have to be restated on the basis of a 10c. reduction of mine prices and a 30c. advance in freight for this territory, making the f.o.b. Buffalo list $4.65 for thin-vein Allegheny Valley, all sizes; $4.45 for Pittsburgh mine-run and $3.95 for Pittsburgh slack, all per net ton.

Anthracite—The supply is about normal here and the lake shipments are now well up to the average, though the late entrance into lake loading by all but one shipper has reduced the season amount as compared with last season to June. A holiday last week reduced the total somewhat. City consumers complain that they are not getting their coal when they ask for it, and some of them are inclined to complain; but the authorities are firm. The distribution goes by rule. The Government fuel office is in full operation, but no great amount of regulation work has to be done there. The shippers see to that.

The great pressure for coal comes from Canada, but the rules are fixed and they are kept in that trade the same as at home. Some buying of bituminous there is reported, but considering its plentifulness the consumer is not embracing the opportunity as he should. It is reported that farmers are cutting quantities of wood, but the Buffalo consumer still depends on the mines, even though the partial giving out of natural gas will increase the winter consumption of anthracite perhaps a half.

Shipments by lake for the week were 72,450 net tons, of which 30,900 tons cleared for Chicago, 20,450 tons for Duluth or Superior (consignee's option after sailing), 10,300 tons for Sheboygan, 4500 tons for Milwaukee, 3300 tons for Manitowoc and 3000 tons for Hubbell. Rates are 75c. to Hubbell, 60 to 65c. to Chicago, 55c. to Milwaukee, 50c. to Manitowoc and 48c. to Duluth.

Shipments for May were 293,850 tons as against 424,700 tons for May last season; for the present season, 452,606 tons as against 622,495 to June last season.

DETROIT

Neither bituminous nor anthracite show increase in shipments. Lake movement below expectations.

Bituminous—Both dealers and consumers are inclined to view the outlook in the matter of Detroit's future coal supply with a good deal of apprehension. The present movement of coal into Detroit little more than meets current requirements, and no indications that a more plentiful supply will be obtainable are visible. Receipts of bituminous coal in Detroit during May averaged about 415 cars daily, while to the remainder of the state only 444 cars were supplied. Coal men place Detroit's normal requirements at approximately 700 cars. This estimate, however, was made several years prior to the war and the present needs probably are greater.

The shipments arriving in Detroit differ from the supply received in previous years in that the larger part of the consignments are made up of mine-run coal. While there is a certain amount of slack, nut and pea coal coming with the mine-run, the quantity is said to be insufficient to supply customers who want slack.

The supply of domestic sizes also is said to be much less than dealers would desire. The fact that domestic consumers have not been active buyers has enabled some of the retailers to accumulate large stocks.

Anthracite—Uncertainty as to the supply of anthracite that will be made available in Detroit and concerning the time when it will be sent here continues. Records of the transportation companies show that in May the average daily receipts were only 32 cars, while the remainder of the state was given an average of only 50 cars daily. Domestic consumers who are eager to provide for winter needs are unable in most instances to get orders filled. Retail dealers have only a few tons on hand and are continuing the system in many cases of declining to accept orders when stock is lacking to fill them. The situation is far from favorable to make a success of coal buying week.

Lake Trade—Shipments of coal by lake routes are also falling short of the figures planned by shippers. The movement in May is calculated to have been under 1,000,000 tons a week. Larger shipments are necessary if the Northwest is to have its requirements supplied before winter.

COLUMBUS

Strength characterizes the coal trade in Ohio. Lake trade is booming, and steam and domestic demand holds up well. Production is fairly good.

The coal trade in Ohio territory has remained firm during the past week. Buying for domestic and steam purposes is active. In fact all branches of the trade are vying with each other in getting stocks ahead. The lake trade is active in every way and a large tonnage is being moved to the Northwest. The tone is generally satisfactory under the unusual war conditions. Prospects are for a continuation of the stiff demand.

Domestic business is still one of the most important departments of the industry. The campaign to "Buy Now" is having its effect, and a large amount is being purchased by retailers. Dealers report a heavy demand in all sections as consumers are anxious to get their fuel in for next winter. As a result of the heavy demand many dealers have small stocks and are gradually exhausting their surplus. Retail prices have declined 10c. on the ton to correspond with the reduction at the mines. Little Pocahontas is coming into the local market as most of the production of that section is going eastward. Considerable West Virginia splints are being sold, but the main bulk of the coal now being laid in is from the mines of the Hocking Valley and Pomeroy districts.

Lake trade is strong and the tonnage moving to the Northwest is gradually increasing. The vessel movement is good and lake shippers report greater efficiency than ever. Lake shipping permits have now been granted and all who have lake contracts are participating. The ore movement is also good. Taking it all in all the prospects are good for the early filling of lake requisitions.

Steam business is one of the strongest points in the market. The larger consumers are buying both for present and deferred delivery, following the policy of laying in a surplus to guard against emergencies. Railroads are heavy consumers and in some districts are taking about one-third of the output. The smaller users are also trying to insure a fuel supply by making connections and filling available storage space with surplus stocks.

Production has been rather good despite the fact that a holiday intervened during the week. The day following was also a holiday at most mines. Extreme hot weather is having an effect in reducing the production. Labor shortage is reported in certain mining districts.

Prices on short tons f.o.b mines are as follows:

	Hocking	Pomeroy	Eastern Ohio
Sized grades	$2.60	$2.95	$2.60
Mine-run	2.35	2.70	2.35
Screenings	2.10	2.35	2.10

CINCINNATI

Continued heavy demand features all departments, increased freight rates to become effective having given an additional stimulus. Trade is settling down to a summer of unprecedented activity.

One of the outstanding features of the past week in the coal trade was the announcement of increased freight rates, effective June 25. Inasmuch as the increased rates will add about 30c. a ton to the cost of coal in Cincinnati, the immediate effect was a still further increase in the volume of orders, many consumers being brought to an immediate decision to order their winter supply who had until then delayed in placing their orders. Of course, such orders in the vast majority of cases will not be filled before the new freight rates go into effect, as dealers have for some time found it impossible to keep up with their orders. The additional freight cost will be charged from the date indicated, it is generally assumed, even on coal already in the yards, as the higher freight rate will be part of the replacement cost of all fuel in this section. Dealers generally, in accepting orders or in soliciting them, are warning consumers that prices cannot be guaranteed, and that orders cannot be accepted save for delivery at such prices as may be prevailing at the time of delivery. In general, this is not having the effect of retarding orders, however, the number of consumers who are holding off on account of the present undeniably high prices being comparatively small, and of no importance in the market, in view of the inability of the trade to take care of the business already booked.

LOUISVILLE

Demand for all grades of coal good, with numerous inquiries from industrial concerns for stocking coal. Car supply still short, with labor steadily leaving mines for other industries.

A 10c. per ton reduction was made in the mine price of lump coal last week, thus placing the new price at $2.55. However, retail dealers will average inbound shipments en route at that date with coal on hand in yards, and the difference will not be much more than 3c. a ton. During the past two weeks the weather has been hot, and domestic consumption has necessarily been light for immediate use. However, stocking orders have been plentiful, and the domestic demand, from the viewpoint of operators, jobbers and retailers, has been much better than in any former year on record.

The 25 per cent. increase in freight rates recently announced by Director General McAdoo is expected to have little real effect on business, as a general increase affecting everyone alike will merely mean that the ultimate consumer will have to pay the freight. Few orders have been taken by the coal trade that did not carry provisions subject to change in event of increases in freight rates; whereas in many trades prices were made f.o.b. points to which merchandise had first to be shipped, there was little of this in the coal trade. However, with thousands of merchants endeavoring to get under cover between now and June 25, it is expected that railroad tonnage movement will be considerably increased, resulting in a still further shortage of cars and labor.

Retailers through their local board have been endeavoring to secure an increase in margins due principally to the increased cost of all labor, which has resulted in the margin being a bit short of what it was a few months ago, when it was made effective. At the present time it is next to impossible to secure men for loading and unloading cars in the local yards.

The daylight-saving plan has had a remarkable effect on the volume of coal consumed by public service corporations during the past few weeks. The industrial load during the daytime has been much heavier this year than usual due to general industrial activity, but with daylight until nearly 9 o'clock, domestic, store window and other consumption has fallen off materially, resulting in a corresponding decrease in the fuel consumption.

BIRMINGHAM

Trade strong and active in both domestic and steam sizes. Supply perhaps a little improved as a whole. Car supply good, but mine workers are not yet putting in full time, which is preventing any appreciable increase in the output.

As far as inquiries go, local conditions are highly satisfactory, the supply being the matter of concern, as has been the case for some time. Both steam and domestic users are insistent upon shipments, and the deficiency in the available tonnage is furnishing a knotty problem for the brokers and distributing agencies in apportioning it among their customers, with the due regard which has to be given to the priority class.

Domestic wholesale and retail prices were boosted 45c. per net ton on May 16, when the wage agreement allowing this increase was placed in effect, and suffered a reduction of 10c. per ton in accordance with the agreement in connection with railroad-fuel contracts. Receipts of domestic coal continue light, with a good demand from the householder. Retail prices are about as follows on prepared sizes: Big Seam, $5.60; Cahaba and Black Creek, $6.25; Corona, $5.90; Montevalle, $7.15.

There is still a pronounced shortage in steam coal to cover requirements, but as this condition has obtained for some time customers are registering few complaints, merely exerting their efforts to get as near as possible to their approximate needs. Mine price schedules have changed twice recently, and the following prices are now in effect:

	Prepared Sizes	Mine-Run	Slack and Screenings
Big Seam	$2.80	$2.50	$2.20
Cahaba, Black Creek, Brookwood and Blue Creek	3.45	3.20	2.80
Pratt, Jagger, Jefferson, Nickel Plate	3.00	2.70	2.40
Corona	3.10	2.75	2.40
Montevalle	4.35	2.75	2.50

Coke

CONNELLSVILLE

Labor performance unsatisfactory; car supply causes little difficulty. Better coke and more efficient blast furnace operations. Effect of freight advances. Production stationary.

With the increased car supplies in the Connellsville region the past few weeks a shortage of labor has been uncovered, and in general the limit in production now is the supply of labor rather than the supply of cars. Frequently cars have to be held over a day for loading. It is asserted that there is a sufficient number of men on the payrolls, but the men do not work full time, hence there is a shortage in performance rather than in men. However, there have been numerous holidays lately, religious and otherwise, and from now to Independence Day labor performance is expected to be better.

Connellsville coke production has been running at about 340,000 tons a week for several weeks past, and it develops that this amount is nearly if not quite sufficient for the operation of blast furnaces now dependent on the region. In 1916 the movement was about 420,000 tons a week, but since then the completion of many by-product ovens has decreased the requirements for Connellsville coke, though much Connellsville coal is moving out instead. In the winter it appeared, from a study of the losses in production by the furnaces, that for full operation close to 375,000 tons of Connellsville coke would have to be supplied, but it now apears that with regular shipments the quality of coke has come closer to standard while the furnaces do not have to bank or run at gaited rates, the result of these influences being that more pig iron is made per ton of coke and the increase in pig-iron production has been greater than the increase in coke production.

The freight advances that go into effect June 25 are as follows on Connellsville coke: When the present rate is 49c. or less per net ton, 15c., this applying to practically no Connellsville coke; on 50 to 99c., 25c. applying to Pittsburgh and making the new rate $1.15; on $1 to $1.99, 40c., applying on Wheeling and the valleys, making a rate of $1.75, on Cleveland making the rate $2.15 and on Erie making the rate $2.20; 60c. on rates $2 to $2.99, making $2.60 to Toledo and Buffalo.

The Connellsville "Courier" reports production in the Connellsville and lower Connellsville region in the week ended May 26 at 340,100 tons, a decrease of 3170 tons.

Middle Western

GENERAL REVIEW

Dr. Garfield's order reducing prices on Illinois and Indiana coal 10, 15 and 20c. per ton the principal event of the week.

Coal producers received a considerable shock during the week past when they were notified of a 10c. per ton reduction in the prices of all grades, and the cancellation of all temporary clean coal permits except to the mines that had washers and mechanical devices.

A noteworthy feature of the past week at several producing centers is the increased car supply, some operators receiving all the cars they could load. Dealers and domestic users were optimistic over the price reduction, but the news of a substantial increase in the freight rate of more than enough to overcome the reduction in coal prices acted somewhat as a dampener.

The continued heavy demand for prepared coal and the slack fine coal market has caused the sales managers of quite a number of companies to take on mine-run orders, much to their dislike and to the detriment of those depending on them for lump, egg and nut coal.

The hard coal situation continues to grow worse each week, and it begins to dawn on all fuel users that they will be compelled to depend on the Middle West producers for coal and forget they have heretofore used hard or Eastern smokeless.

CHICAGO

Decrease in prices of coal and increase in the freight rate cause more or less confusion.

A wild scramble for better grades of coal from the Williamson-Franklin County field was caused by the substantial freight-rate increase during the week. All producers in southern Illinois, including Saline County, have business booked of sufficient volume to operate their mines with a full-car supply for an indefinite period. Dealers are insistent that their orders have preference over those of their neighbors, and the result is that sales managers are compelled to listen to entreaties daily until their position has been rendered one of constant strain.

While there is a good market for all grades of prepared coal in this market, screenings from the central and northern Illinois fields are selling off. Southern Illinois operators are not experiencing any difficulty in disposing of their fine coal at full Government price.

Quotations in the Chicago market are as follows, per net ton f.o.b. cars at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Spring-Springfield	Carterville	Grundy, La-Salle, Bureau and Will.
Steam lump	$2.55@2.70	$2.55@2.70	$2.95@3.10	$2.55@2.70	$2.55@2.70	$3.25@3.40
Domestic lump	2.55@2.70	2.55@2.70	2.95@3.10	2.55@2.70	2.55@2.70	3.25@3.40
Egg or furnace	2.55@2.70	2.55@2.70	2.95@3.10	2.55@2.70	2.55@2.70	3.25@3.40

MILWAUKEE

An organized effort is being made to round up coal orders. Receipts by lake continue slow. Wisconsin's allotment of anthracite reduced.

A coal-ordering drive is on in Milwaukee and consumers are responding satisfactorily, according to State Fuel Administrator Fitzgerald. When the investigation of the cost of handling coal over the docks is completed, and prices are fixed, it is expected that ordering will become more brisk. It ought to be an easy matter to determine Wisconsin's coal needs during the winter season without waiting for individual orders to pile up, as reliable statistics covering the coal business for years past serve as an open book.

The movement of hard coal up the lakes is slow at present. Milwaukee has been averaging one medium cargo per week. Since last week's report one cargo of 7897 tons has been received. Soft-coal receipts during the same period aggregated 100,404 tons. Cargo receipts for the season thus far embrace 73,045 tons of anthracite and 422,091 tons of bituminous.

With one exception, firms which have received hard coal are delivering the same to consumers at whatever price the fuel administrator may name. The leading dock company is holding up deliveries, however, until some adjustment as to price has been reached. The situation is entailing hardship upon a small army of middlemen who have been forced to maintain their teaming outfits in idleness for some time. Coke is being delivered freely, however.

Wisconsin is to get less anthracite this year, a cut of 13.36 per cent. in the state's allotment having been ordered by Federal Fuel Administrator Garfield. The state will be allowed 1,024,000 tons of anthracite for use during the year beginning Apr. 1, 1918, and ending Mar. 31, 1919. Last year's quota was 1,181,926 tons. If increased labor shortage should still further curtail the total production, Wisconsin will get proportionately less. In consequence of the reduction in the anthracite supply, consumers who have been using anthracite exclusively in the past will have to put up with 10 per cent. of bituminous coal.

ST. LOUIS

An unusually quiet market on steam sizes, with no railroad buying at all to mention. A surplus of coal still on hand in the Standard field and a fluctuating market. Car supply fair. Critical situation in the Middle West on account of hard coal ruling.

The situation in the West at the present time is one of extreme anxiety on the part of the public, who have been led to believe throughout the spring months that they would receive their share of anthracite coal. Now comes advice from Washington that no anthracite coal will be permitted to come to Mississippi River points or west.

Throughout the entire State of Missouri there is much hardship and an enormous loss in actual money as a result of this ruling, for equipment in thousands of homes must be thrown out and discarded in order to make room for furnaces that can burn another kind of fuel.

The dealers have booked orders for thousands of tons, and the public are insisting that they get the coal. A small tonnage of anthracite is moving in; so small, that it does not count for anything.

The conditions in the bituminous industry have not changed much in the past several weeks. In the Carterville field there still continues to be a demand that so far exhausts the supply that it will take months before the mines will be caught up.

The car supply is not good on the Iron Mountain or Illinois Central and transportation on those roads is also bad.

Conditions in the Mt. Olive field are extremely good. The demand is equal to the supply. Working conditions are better than usual, the car supply is fair, and the transportation right now is nothing to complain of.

In the Standard field the screening market is in a deplorable shape. Coal restricted to St. Louis brings as low as $1.40 for screenings. Mine-run is $1.90, while lump has been going as low as $2.20.

Railroad buying is extremely light and many mines have coal unbilled daily. Some are unable to work at times on account of no business, and yet in the face of all this there is a crying demand for coal outside of the Missouri zone line that cannot be met. It is freely admitted that the operators in western Missouri and the Kansas field cannot begin to take care of the demand for coal in their territory when the time comes, and yet with the surplus of coal in Illinois, that territory must suffer and the Illinois mines remain idle.

The price of coal was increased 5c. per ton retail. It should have been 15c., but on account of the decrease in the mine price of 10c. on May 25 it was evened up with a 5c. increase.

There is no smokeless coal of any kind or character coming in, with the exception of a little from Arkansas, which is not giving satisfaction.

The prevailing market is, per net ton f. o. b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard

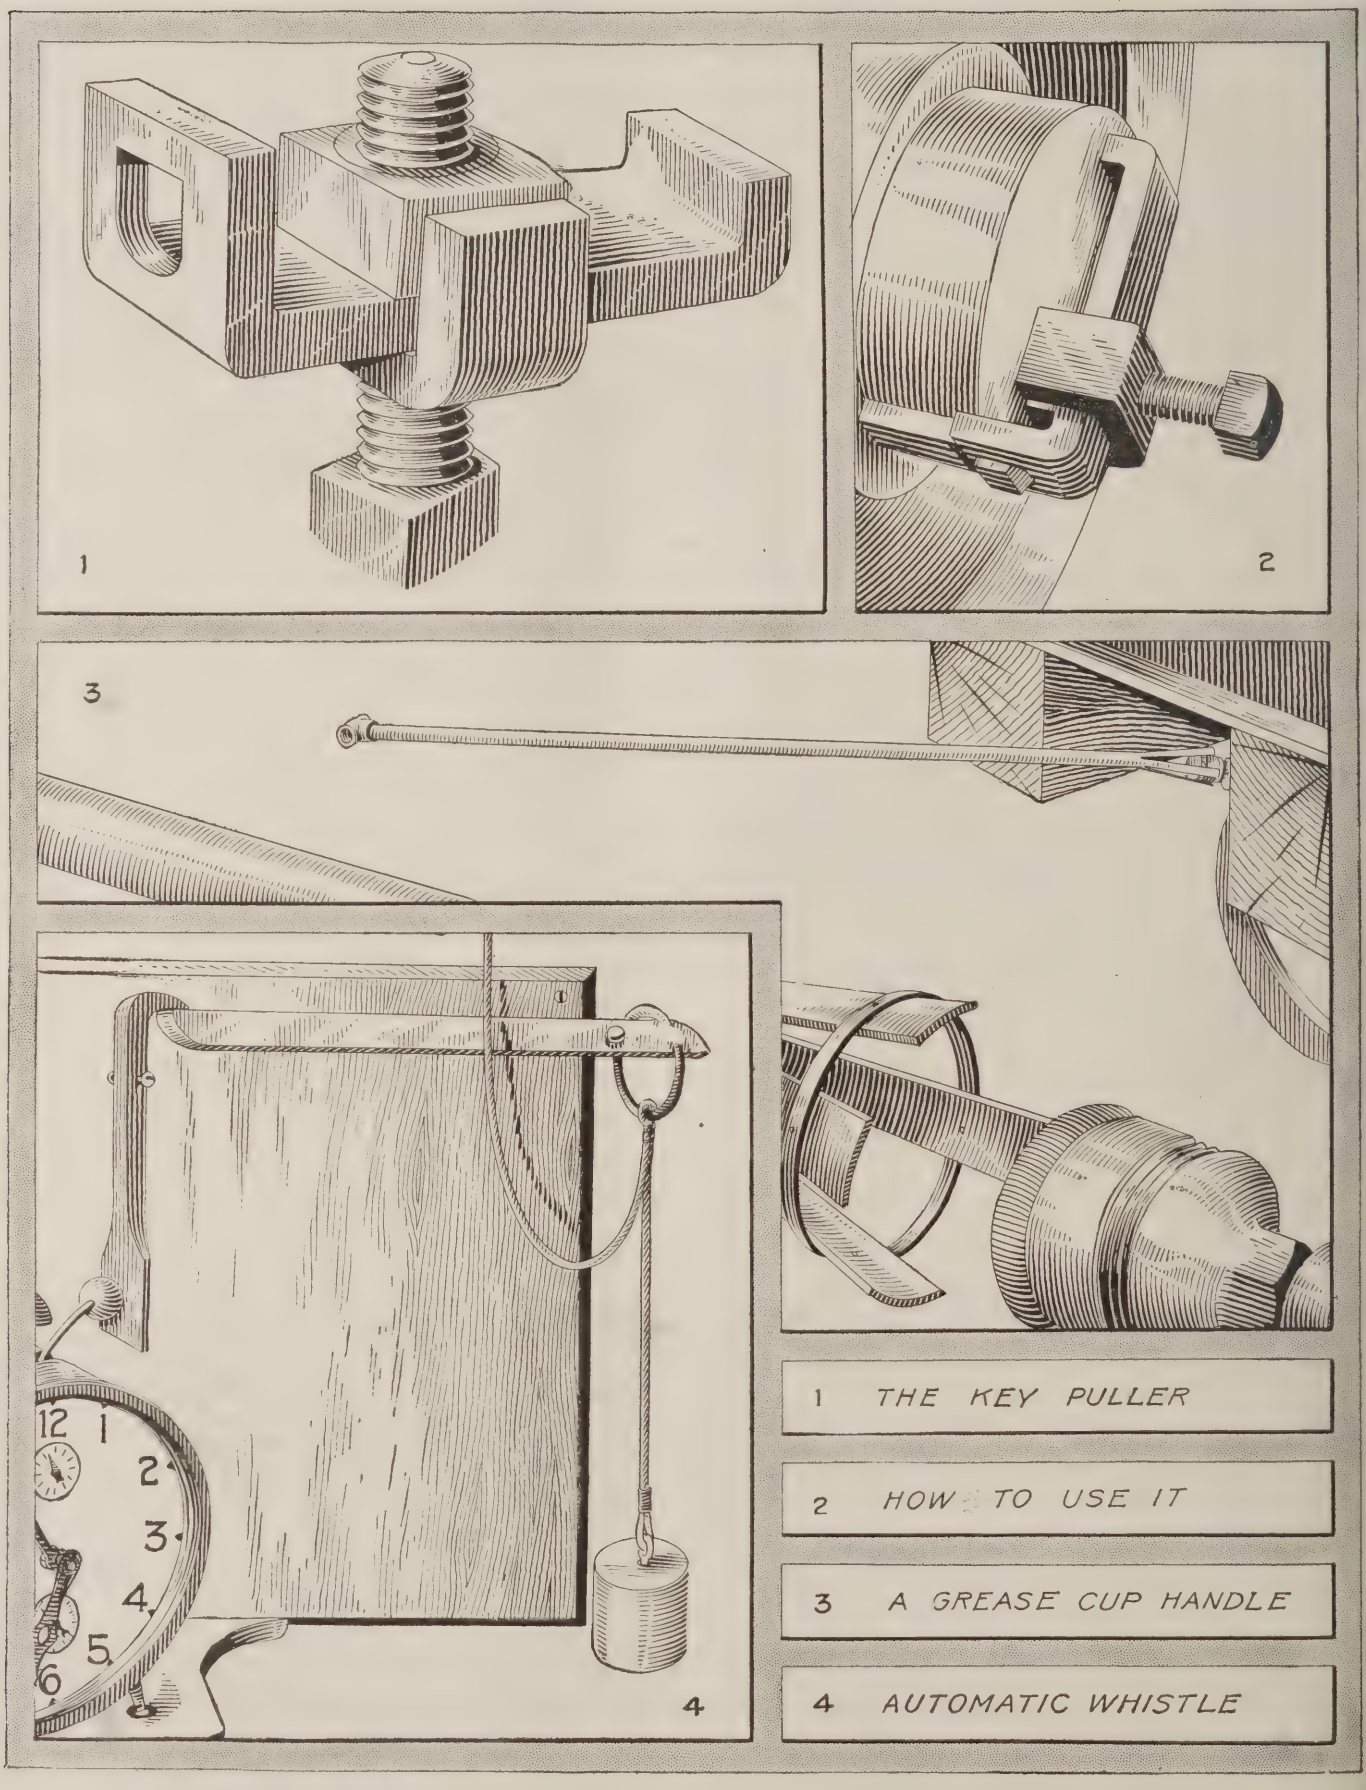
COAL AGE

Volume 13 NEW YORK, JUNE 15, 1918 Number 24

Load it Clean

by



Rufus T. Strohm

It's a whale of a job that you're facin'—
You fellows with shovels an' drills—
For the railroads an' fact'ries is racin',
An' so is the shops an' the mills;
An' there mustn't be haltin' or slowin'
Of engine or belt or machine,
So dig into the work—make a showin'—
But in loadin' the coal, keep it clean!

If your output is dirty an' bony,
An' you're blind to the slate an' the rock,
Why, your love for your country is phony,
Or your patriotism's in hock;
For you've got to be white, or you're yellow,
Since there ain't any 'twixt-an'-between,
So come on—be a regular fellow—
When you're loadin' the coal, load it clean!

If a transport chock-full of our younkers,
Takin' your boy an' my boy to France,
Has a load of bum coal in her bunkers,
She's got less than a ghost of a chance;
For she's bound to destruction an' ruin
If a submarine bobs on the scene,
So, for God's sake, take care what you're doin'!
When you're loadin' the coal, load it clean!

Hoisting Water in Tanks by Electricity

By GEORGE W. HARRIS
Editorial Staff, "Coal Age"

"OLD COMPANY'S LEHIGH" for many years has been favorably known the length and breadth of the land wherever anthracite coal has been prized as a domestic and steam fuel. The main source of this coal is the Panther Creek Valley, adjoining the eastern end of which is the celebrated mine at Summit Hill where the old workings long have been burning and destroying thousands of tons of "Big Vein" coal. Mauch Chunk, Penn., is not far distant, and tourists visiting this old town, in the midst of the "Switzerland of America," generally went to this burning mine, which is on a site overlooking the Panther Creek Valley. A few years ago the fire in this old colliery was isolated by building a barrier pillar shutting off the old workings from the main body of coal adjoining. The old town of Tamaqua is at the western end of the Panther Creek or main holdings of the Lehigh Coal and Navigation Company.

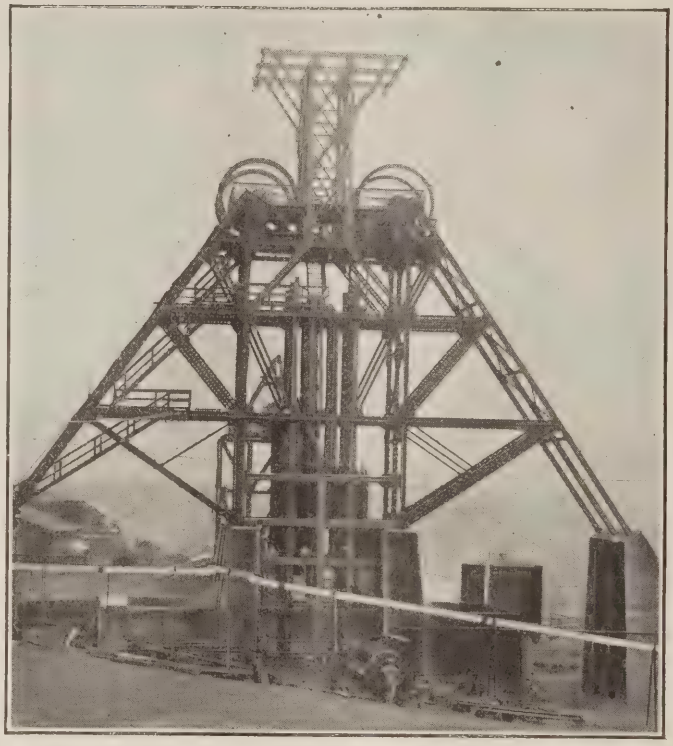

FIG. 1. HEADFRAME AT TAMAQUA COLLIERY

Nearing the century mark of existence, this veteran coal company looks back on many years of achievement. The history of this pioneer organization is most interesting. The original companies, which later were merged into the Lehigh Coal and Navigation Co., were the first coal companies in existence on any scale in the anthracite field. The Lehigh Coal Mining Co. began operations in 1793 and the Lehigh and Navigation Co. was founded in 1818. In 1820 these two companies combined under the name of the Lehigh Coal and Navigation Co., thus establishing its claim to the title of the oldest coal-mining company in existence in the region.

The output of this company in 1917 was about five million tons, or an increase of 31 per cent. over that of the preceding year. Its operations are being enlarged rapidly, and an aggressive policy of expansion and development looks to a substantial increase of tonnage this year over that of 1917—this in the face of a decreasing labor supply and increasing difficulties of operation.

Among the matters of serious import to the Panther Creek operator is the water problem. The steep mountain sides run water quickly to the valley below. In the case of intervening broken surface, on account of mine falls and subsidence of surface, the water is diverted to underground workings. As mining progresses, the difficulties of handling mine water will increase with greater depth and quantity of water to be removed. At times water floods the workings almost beyond the ability of equipment to handle it. The water drainage gangway alone carried 40,000 gal. per min. in one instance during a wet season.

In the early '80's, hoisting water from the mines by tanks was started by the Lehigh Coal and Navigation Co., and during the succeeding years this method has been given a thorough trial. Coaldale No. 8 and Lansford No. 6 shafts are the oldest water hoists in the Panther Creek Valley and likely the first installations of the kind in the anthracite region. Coaldale No. 9 shaft has no headframe, the water being discharged into a water level tunnel below the surface. The two steam water hoists at shaft No. 10 of the Greenwood colliery have a single wooden headframe, common to both hoists, equipped with a unique water seal equipment which will be treated in a separate article. Lansford No. 4 and No. 6 water hoists and the two water hoists at No. 14 shaft, Tamaqua colliery, all have steel headframes. The No. 14 shaft hoists include a steam and an electric motive power; the latter was installed a year or so ago and is worthy of special note.

The water hoists enumerated total eight. In addition each shaft through which coal is hoisted is so arranged that tanks can be installed at once in an emergency. The false bottom of 3-in. plank which rests on shaft timbers about 4 or 5 ft. below the cage landing at the bottom can readily be removed; a 30-ft. sump is thereby available in which water tanks can be filled. When the false bottom is in position it tends to keep mine cars or other large objects which fall into the pit from going to the bottom of the sump.

At Nos. 4, 6, 10 and 14 shafts the water hoisted to the surface is spilled into reservoirs from which the water runs by gravity to the respective breakers. At other breakers the creek water must be used. The wet preparation of anthracite coal necessitates the use of large quantities of water. For every 1000 tons of coal prepared, practically 1000 gal. of water are required per minute. Possibly about the only good word a coal operator will have for mine water is in this connection. In very dry seasons or during an extremely cold winter water for breakers and boilers may be a most serious matter. In portions of the anthracite region during the past winter the water in some colliery reservoirs froze

to such a depth that driven wells were substituted to supply the requisite water for certain operations.

At shaft No. 14, of the Tamaqua colliery, there is a steam-operated hoist and another one operated by electric power; the latter hoist has been in operation almost two years. The plan of Tamaqua colliery is shown in Fig. 2, and a section of the basin at shaft No. 14 is given in Fig. 3.

Tamaqua colliery adjoins the town of Tamaqua and is situated in Schuylkill County, Pennsylvania. The seams at this point were developed by shafts from which tunnels were driven to intersect the various beds at different levels. The water shaft No. 14 (*A*) and the coal shaft (*B*) were both started about the same time in 1906. Shaft *A* was sunk to a depth of 826 ft. and a short tunnel driven from the bottom to serve as a sump. Other tunnels were driven as shown on the section and map—also several shafts for various purposes. Three levels were opened up from the main shafts at depths of about 406, 589 and 829 ft. respectively, below the surface. These tunnels mainly developed the coal seams on the south dip. The second level tunnel constituted the principal development; it was extended to cut all seams in Locust Mountain on the north, a distance of 2160 ft.; on the south, this tunnel was driven a distance of 4300 ft. from shaft *A* to reach the seams in Sharp Mountain. Seven seams are worked on 2nd level north —the Sandrock, Top, Middle and Bottom splits of the Mammoth, the Seven-foot and the Buck Mountain beds. On the 2nd level south, the Orchard, Primrose, Top and Bottom splits of the Mammoth and the Buck Mountain seams are mined.

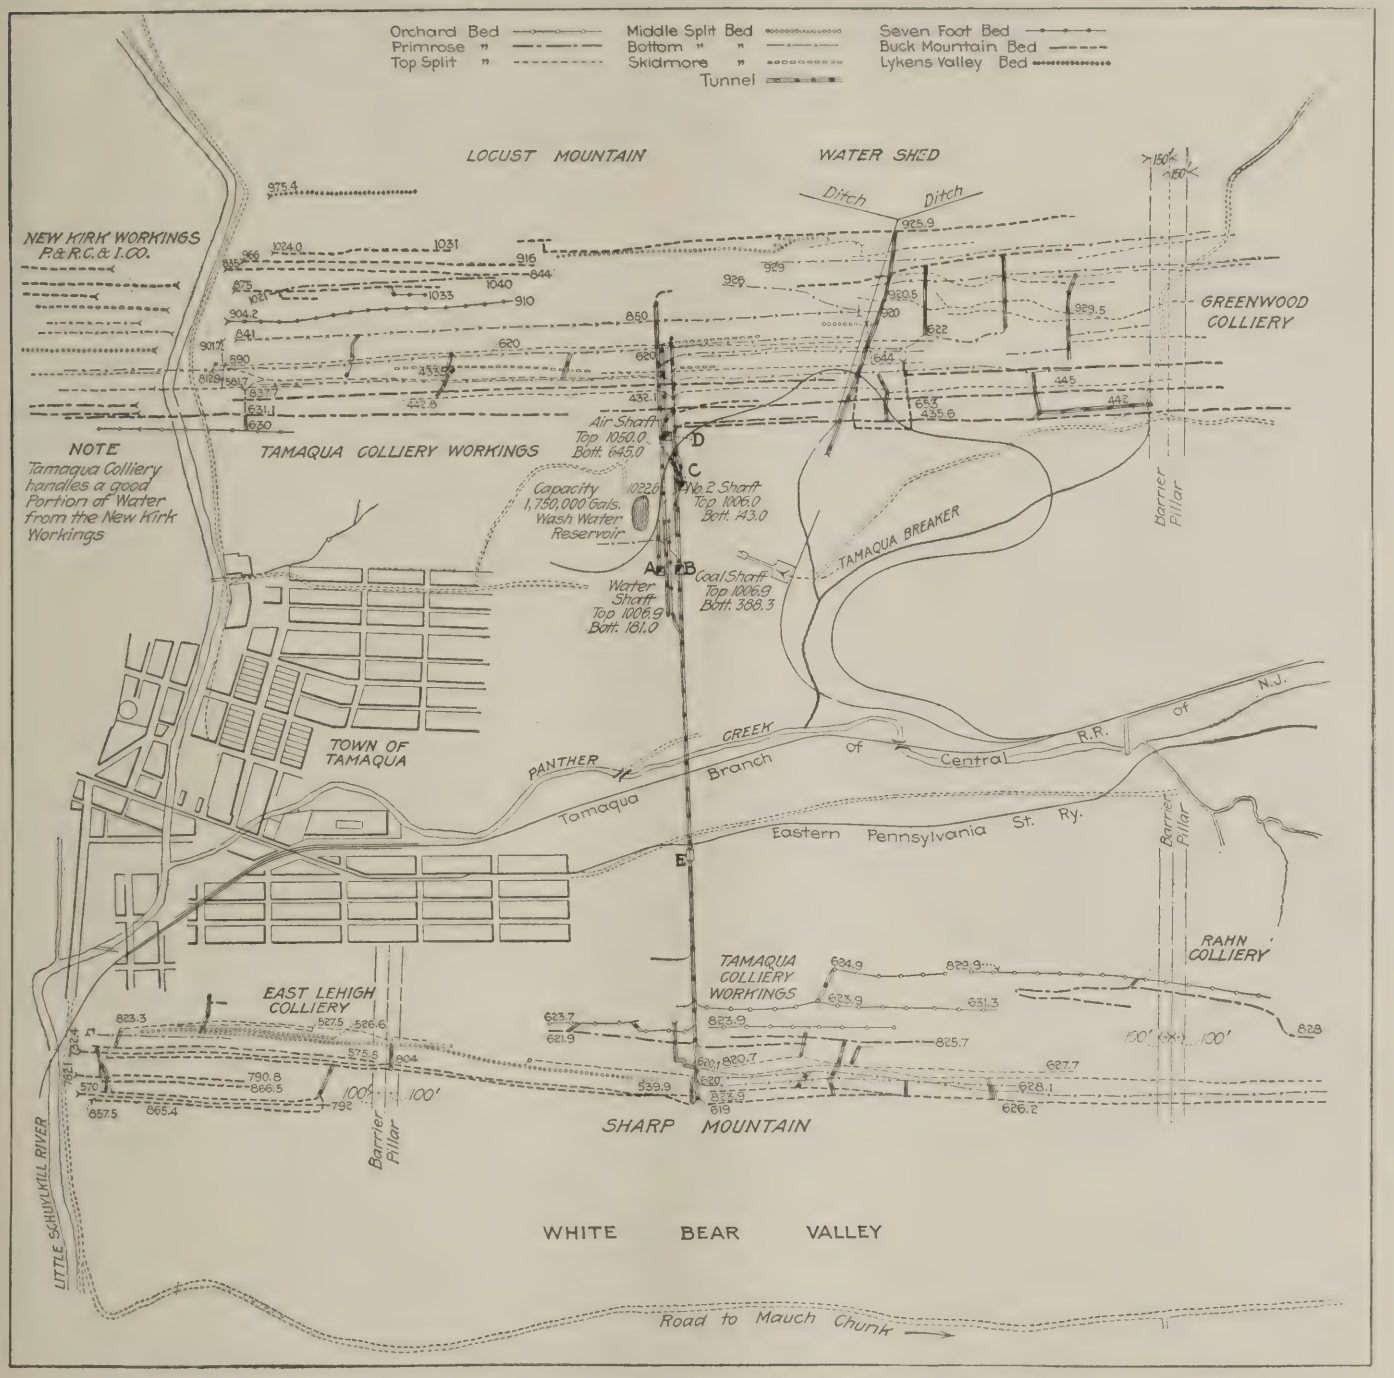

FIG. 2. GANGWAYS, TUNNELS, SHAFTS AND SURFACE FEATURES OF TAMAQUA COLLIERY

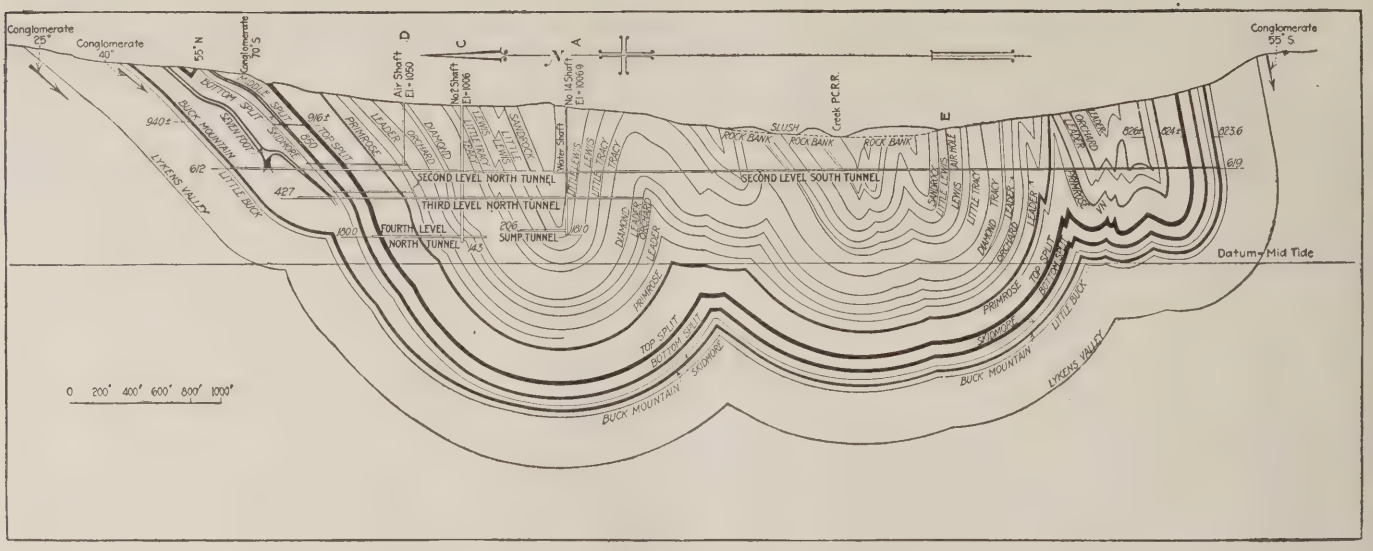

FIG. 3. CROSS-SECTION OF BASIN AT WATER SHAFT AT TAMAQUA COLLIERY

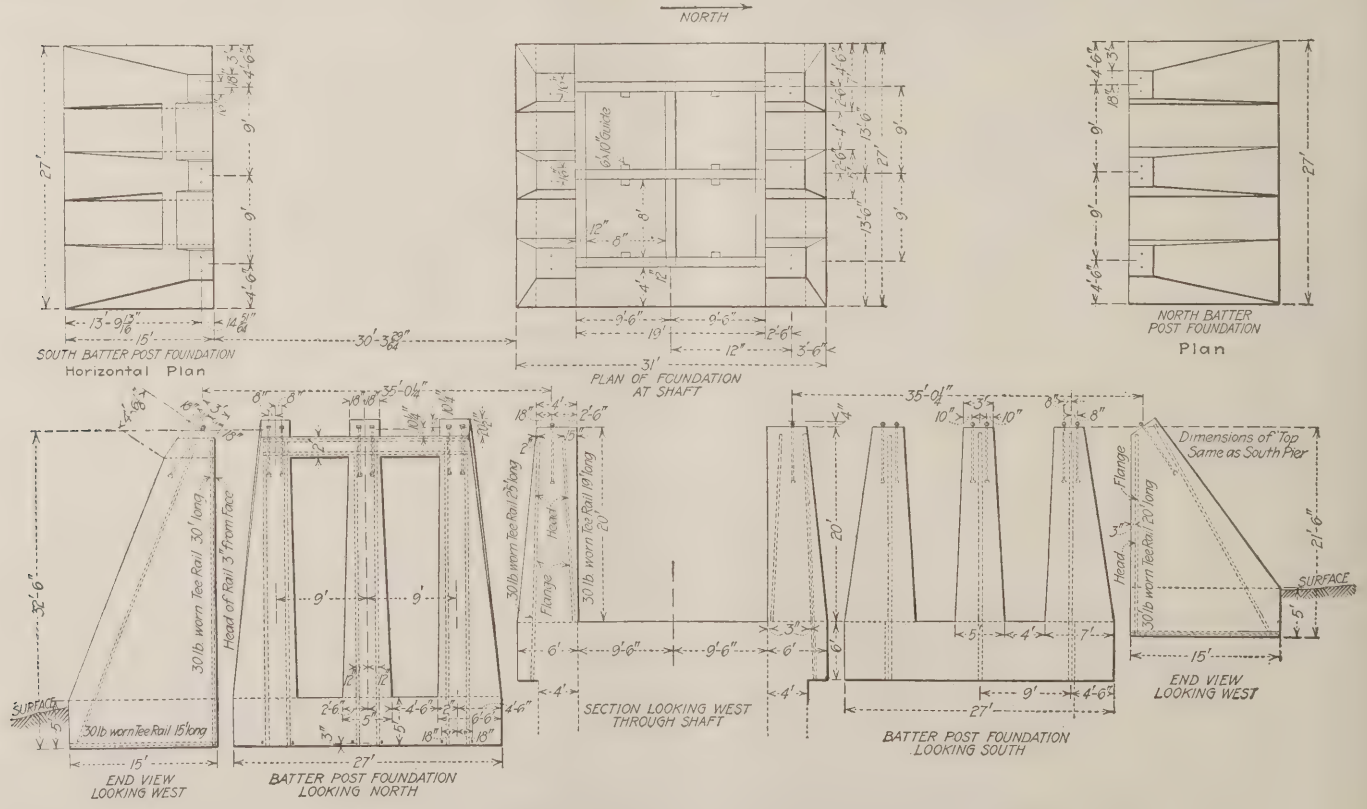
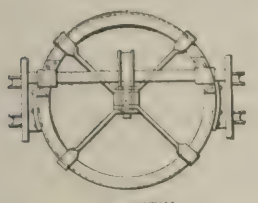
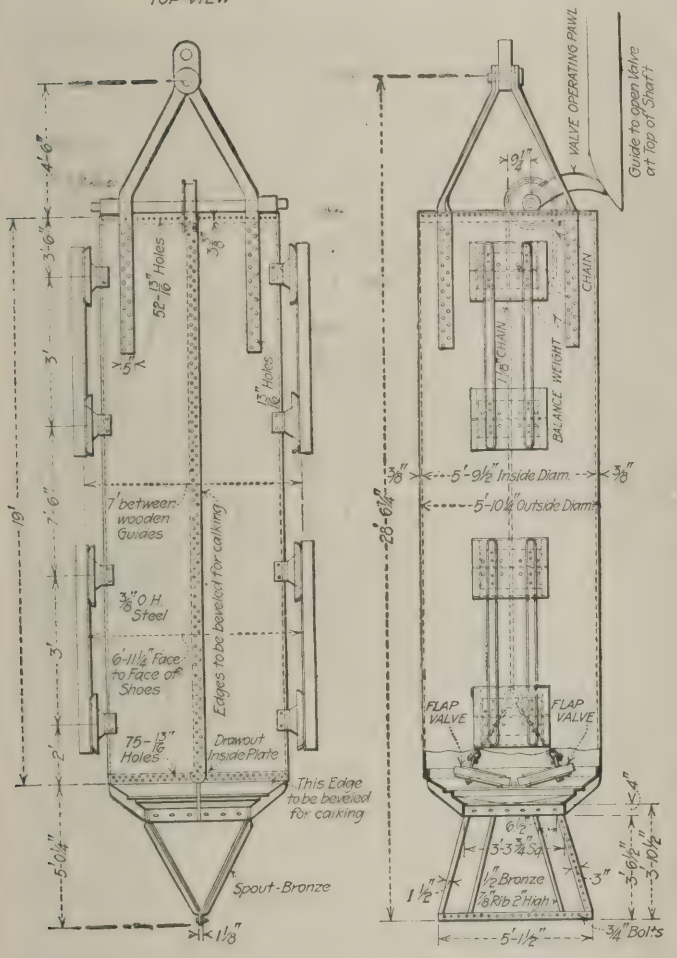
Development to the east and west of the main or 2nd level is as follows: The south tunnel workings extend 3400 ft. east to a barrier pillar between Tamaqua and Rahn collieries, and 2400 ft. west to a barrier pillar between Tamaqua and East Lehigh collieries. The north tunnel workings extend 3600 ft. east to a barrier pillar between Tamaqua and Greenwood collieries, and 3800 ft. west to Little Schuylkill River, the center of which is the dividing line between the Lehigh Coal and Navigation Co. and the Philadelphia & Reading Coal and Iron Co. at the latter's New Kirk old workings. Limited mining in the Primrose seam was carried on during early times and abandoned in 1874. Thus it is seen that a large amount of territory has been opened up. As to the drainage area, the situation can readily be grasped by reference to the map and section. From the top of Sharp Mountain on the south, extending over the adjoining mine workings, there is a drainage area of about 110 acres on the Tamaqua colliery tract. Similarly on the north, Locust Mountain furnishes a drainage area of about 240 acres. Between these two areas, in the center of the valley, the water drains into Panther Creek, which flows into Little Schuylkill River at Tamaqua.

It can readily be seen that considerable water will find its way into the workings of the Tamaqua colliery in wet weather. Conditions are somewhat improved on a portion of the Locust Mountain water shed by ditches above the outcrops. These ditches catch water running down the mountain slope above and divert it to a trough which carries it over the workings to Panther Creek. Underground, the bulk of the water at Tamaqua col-







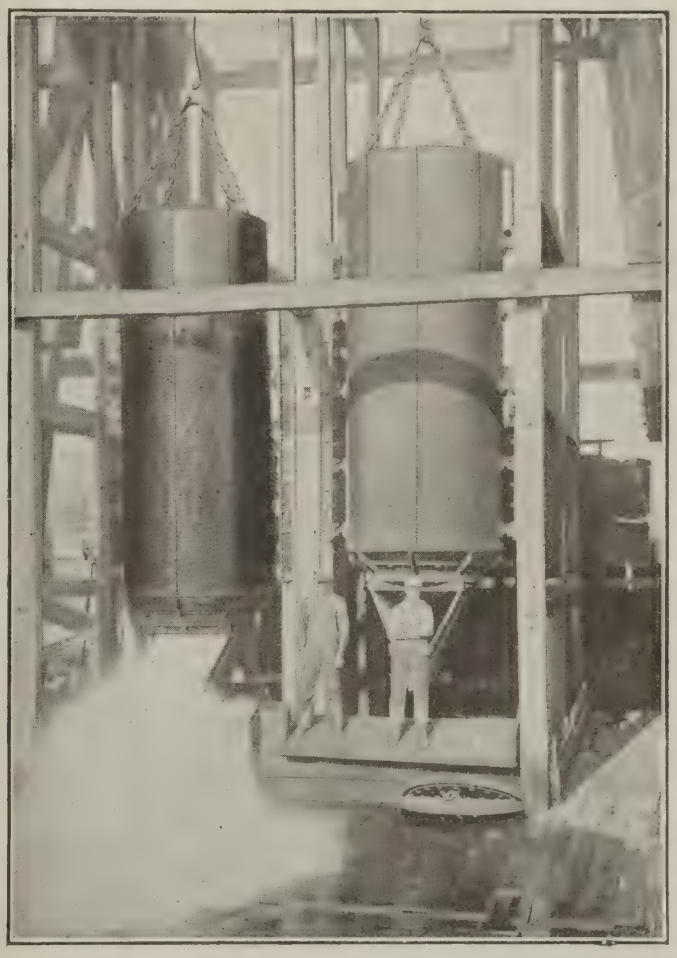


FIG. 4. DETAILS OF HEADFRAME FOUNDATIONS AT SHAFT NO. 14 WATER HOIST

liery is handled by the water hoists at shaft No. 14 during normal times. In the south tunnel a 2000-gal. centrifugal pump is now being placed which will be used in wet weather to pump water up a 300-ft. columnway to the surface. Ordinarily this water will run to the water shaft. On the 4th level now being developed at shaft No. 2 there will be installed a triplex pump of 1500-gal. capacity and a 3000-gal. centrifugal. During normal times the triplex will pump water to the 3rd level, where the water will be handled by the tanks.

FIGS. 5 AND 6. DETAILS OF WATER TANKS AND VIEW OF TANKS AT SHAFT

But in wet weather when the water shaft plant cannot hoist all the water, the centrifugal will pump direct to the surface.

In 1916 at Tamaqua colliery, 3,374,000 tons of water were hoisted on a production of 343,000 tons of coal, or 9.8 tons of water per ton of coal. The average for all the collieries of the Lehigh Coal and Navigation Co. in the same year was 6.68 tons of water per ton of coal. The removal of water from mines is a fixed charge whether the colliery works or not. The larger the output of coal per year, the less per ton should be the expense of pumping water. In March, 1917, at shaft No. 14, there were hoisted 29,000 tanks or 88,000,000 gal. of water by the electric and steam hoists. Shaft No. 14 has four compartments, each being 8 x 8 ft. in dimension. Connections between the various tunnels are provided underground at each of the several levels so that all coal is hoisted through the two-compartment coal shaft near the water hoist. The coal shaft compartments are each 7 x 11 ft. in dimension. Tamaqua colliery now produces about 2000 tons of coal daily.

Among the various water hoists of the Lehigh Coal and Navigation Co. perhaps the most interesting installation and the one most deserving of special note is the twin hoist at shaft No. 14. The headframe at this shaft is shown in Fig. 1 and the details of the foundations are given in Fig. 4. An interesting proposition developed in connection with the foundations. Two sets of plans were prepared showing concrete piers for the headframe; one set called for piers 10 ft. high and in the other plan they were made 20 ft. in height. It was found on submitting these plans to the steel companies for bids on the headframe that the plan calling for piers 20 ft. high was the cheaper proposition. The cost of the extra 10 ft. of concrete was considerably less than the cost of the same height of steel work. This was the reason for making the piers as high as they are—the situation is clearly shown in Fig. 1.

The headframe foundations at the shaft were placed on the shaft lining, which is about 4 ft. thick all the way down to rock—a distance of some 30 ft. The concrete is a 2: 4: 6 mixture and is reinforced by old 30-lb. tee rail. Everything connected with these water hoists should be of especially heavy and substantial construction. The electric hoist tank weighs 8½ tons empty and has a capacity of 3600 gal., which adds 15

tons of water, and brings the load to be hoisted up to 23½ tons irrespective of the weight of the hoisting rope. The duty on the hoist is somewhat less as the tanks are in balance.

The steel headframe is shown in Fig. 1. The sheave wheel shaft is 50 ft. above the top of the concrete foundation, and the center of the shaft compartment, on the electric hoist side, is 125 ft. from the center of the hoist drum. An interesting feature of all the Lehigh Coal and Navigation Co. headframes is the contrivance at the top for handling sheaves, etc. In Fig. 1 it is shown as a steel frame rising between the two sets of sheaves with cross beams at the top carrying I-beam and trolley directly over the center of the sheave shaft. In operation the sheaves are hoisted, when necessary, by a block and tackle, run over by the trolley to clear the headframe and then lowered to the ground. When repairs are to be made, a device of this kind is needed quickly and it is a great labor saver.

The tanks used in handling the water at shaft No. 14 are good servants but dangerous enemies. They each weigh 8½ tons empty and when loaded 23½ tons; should the wire hoisting rope break this heavy mass would gain terrific momentum with any distance to fall. Or if a wooden guide works loose, an accident resulting may put the whole shaft out of commission. Overwinds are practically an impossibility in the case of the electric hoist, but in some other installations where it has occurred the shaft has been idle for a day or so and the tank was ruined.

The details of the tanks are shown in Fig. 5. The flap valve at the bottom of the tank is balanced, so that when the empty tank strikes the water at the sump the valve readily opens and the tank quickly fills. As the tank reaches the top of the shaft, a pawl at the side comes in contact with a guide; the valve is thus opened at the bottom of the tank and is held in that position until the water is discharged. A tank discharging its load is shown in Fig. 6. The spout at the bottom deflects the water to one side. The two men in the illustration serve as a scale and impress one as to the capacity of the tanks. One of the tank flap valves can be seen on the floor below the men in question. The photograph from which Fig. 6 was made illustrates conditions at a water hoist where the headframe is constructed of wood. However, except for the presence of timber work and the absence of the massive concrete foundations of shaft No. 14, it might be taken for the latter installation.

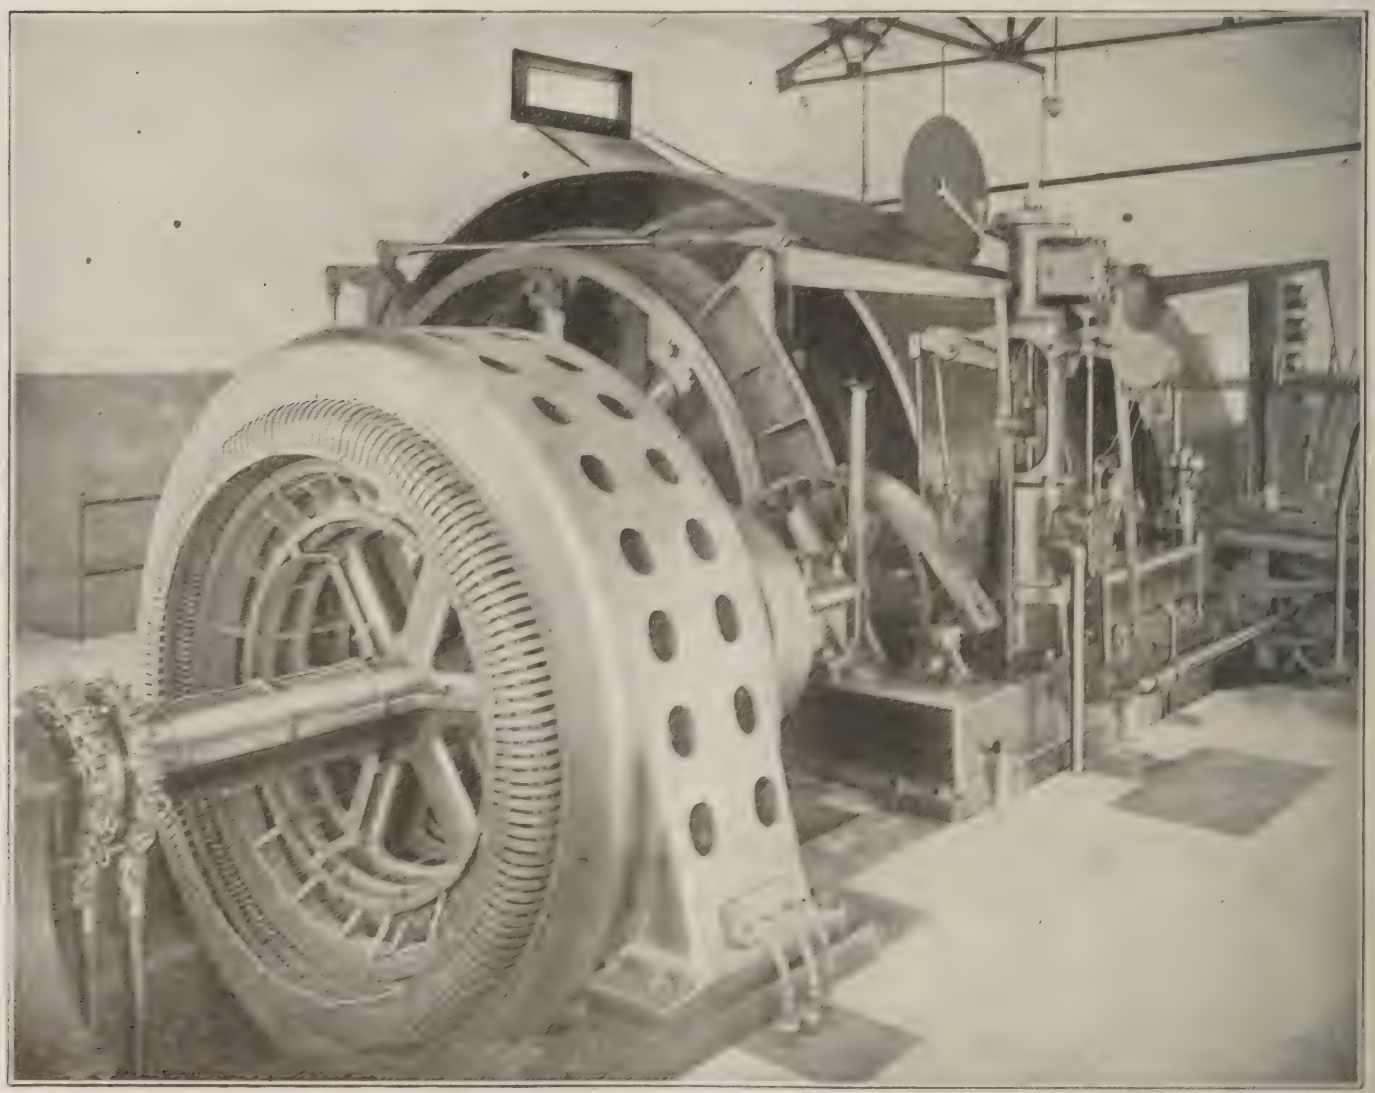

FIG. 1. ELECTRIC WATER HOIST AT SHAFT NO. 14 OF LEHIGH COAL AND NAVIGATION CO.

At the time the headframe foundations (see Fig. 4)

were built at shaft No. 14, provision was also made for handling water as it was discharged from the tanks. These concrete basins, one on either side of the shaft, are shown in Fig. 1; from here the water runs by gravity to a storage reservoir. In the background at the right of Fig. 1 is a water tank built by the W. E. Caldwell Co., of Louisville, Ky. It is a storage reservoir for water for boilers in the vicinity. In commenting on its good qualities, a Lehigh Coal and Navigation Co. official stated that it was painted inside once a year and gave no trouble.

Possibly the point of special interest at shaft No. 14 water hoist is the electrical hoist itself in its substantial building of concrete. Its operation is practically noiseless, the rush of water as it leaves the tank alone calling attention to the operation of unwatering the mines. With the steam hoists the night silence is broken by the exhaust of the engines, accentuated by the periodical stopping and starting of the hoists.

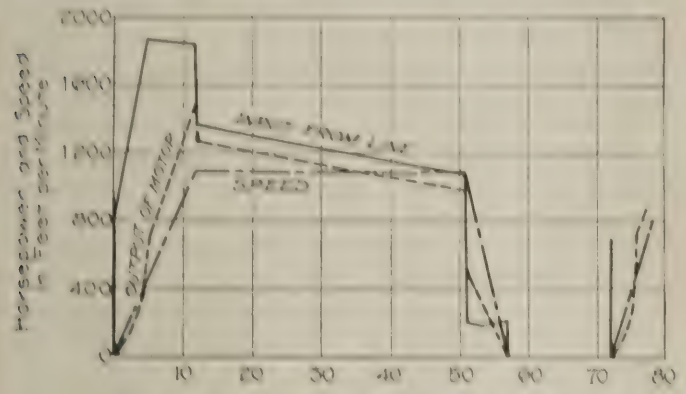

FIG. 8. DUTY CYCLE OF WATER HOIST

The electric hoist (see Fig. 7) at shaft No. 14 is a 1200-hp. machine driven by a slip-ring, three-phase, 2200-volt, 25-cycle induction motor. The hoist itself was built by the Vulcan Iron Works, of Wilkes-Barre, Penn., while the electrical end was handled by the General Electric Co., of Schenectady, N. Y. During the proposition stage, before definite plans were settled upon, three methods of driving this hoist were under consideration. One was by means of a flywheel motor generator set (the Ilgner system) and direct-current hoist motor. Another method called for a synchronous motor-generator set and direct-current hoist motor. And a third method by means of a slip-ring induction motor having a polar-wound rotor to permit of the addition of external resistance to the rotor circuit. The third method was the one adopted. Duty cycles of the three methods were made up and calculated, when it was found that so little was to be gained by the use of either of the first two and much more expensive apparatus that the Lehigh Coal and Navigation Co. was justified in deciding in favor of the induction motor.

This motor operates normally at 300 r.p.m. and is controlled by a liquid rheostat and contactors (see Fig. 9) which are used for reversing on the 2200-volt circuit. The hoist itself is driven from the motor by a single herringbone first reduction gear; the motor shaft is connected to the pinion shaft by a flexible coupling. The pinion shaft carries a band brake. The two drums of the hoist are each 12 ft. in diameter and 5 ft. 2 in. between flanges; they are grooved to stow 865 ft. of 2-in. rope with 23 turns. Each drum is provided with a double post brake, the two being controlled from a common compressed-air cylinder. The hoist is, of course, provided with a modern overwinding and over-speeding device. The engineer's platform is directly behind the center of the hoist, the control levers showing plainly in Fig. 7. A striking feature of this powerful hoist is its compactness. The drums would be practically the same whether steam or electric driven. Contrast this induction hoist with its bedplate 12 ft. square and the floor space which would be required for a 1200-hp. steam motive set.

It is particularly interesting to note just how closely a hoist of this nature can be precalculated. Fig. 8 shows the duty cycle which was calculated during the proposition stage of this job, and the duty from which the duty cycle was calculated is as follows:

Depth of shaft	865 ft.	Maximum r.p.m. of drums	38.75
Inclination of shaft to horizontal	90 deg	Time of acceleration	12 sec.
Weight of bucket (tank)	17,000 lb.	Time of full speed, running	79 sec
Weight of water in bucket	30,000 lb.	Time of retardation	6 sec.
Size of rope	2 in.	Rest period	15 sec.
Weight of rope per foot	6.25 lb.	Equivalent weight of rotating parts of hoist mechanism at 6 ft. radius	75,000 lb.
Type of drum	Cylindrical		
Maximum rope speed in ft. per min.	1,080		

From the duty cycle, the General Electric Co. advised the Lehigh Coal and Navigation Co. that it could guarantee the kilowatt-hours per trip of somewhere in the vicinity of 15.5. After a year's operation of this plant the Lehigh Coal and Navigation Co. divided the total kilowatt-hours consumed by the total number of trips and found that the calculated figure was correct. By inspection of Fig. 8, it can readily be seen that there is an interesting relation between the input from the line, output of motor and speed of the hoist. When power is thrown on, about 800 hp. is instantly developed which in 5 sec. increases to 1850 hp., while the output from the motor is only about 650 hp. During the next 7 sec. the input from the line drops slightly while the output from the motor increases to its maximum of about 1450 hp. Up to this time the speed uniformly accelerates until it reaches 1080 ft. per min. The remainder of the cycle can also be readily followed and requires no special comment. After a rest of 15 sec. the cycle is repeated.

Bird's-eye View of Operations

After close attention to details it often rests the eye and brain to climb to some height and take a bird's-eye view. The main operations of the Lehigh Coal and Navigation Co. are distributed over a valley about 14 miles long by 1½ miles wide at its greatest width. Quite noticeable at a number of points are concrete buildings with red-tile roofs; these are the substations which receive the high-voltage alternating-electric current from the Hauto power plant and convert and transform it to meet local requirements. These substations are the finest of any in the anthracite region.

The Hauto power plant is located on the other side of Locust Mountain in the Nesquehoning Valley, about half a mile west of the Lansford tunnel. It was built in 1909 largely through the efforts and by the financial support of the Lehigh Coal and Navigation Co.; it was recently sold to the Electric Bond and Share Co. Power from this 26,000-kw. station goes to all the plants of the Lehigh Coal and Navigation Co. and also the Bethlehem

Steel Co. and the cement companies in the Lehigh Valley.

The policy of unwatering its mines by water hoists was adopted by the Lehigh Coal and Navigation Co. many years ago. These machines have been efficient and have many points which recommend their continuance. When everything works smoothly, water hoists are satisfactory; but to keep them up to the mark requires considerable inspection of ropes, timber guides, sumps, etc. When the human element enters often too much depends on the personal equation—whether the right man is on the job or not. Of late certain objections to water hoists for local service in the Panther Creek valley have developed. However, this is not a general statement. Whether water hoists should be installed at a mine in another section is a matter for an engineer to investigate and settle on its merits in each case.

The Lehigh Coal and Navigation Co. is a pioneer as regards the introduction of mechanical devices at coal mines—in the last five or six years, especially, it has installed much labor-saving machinery. This company has also conducted many experiments. An account of

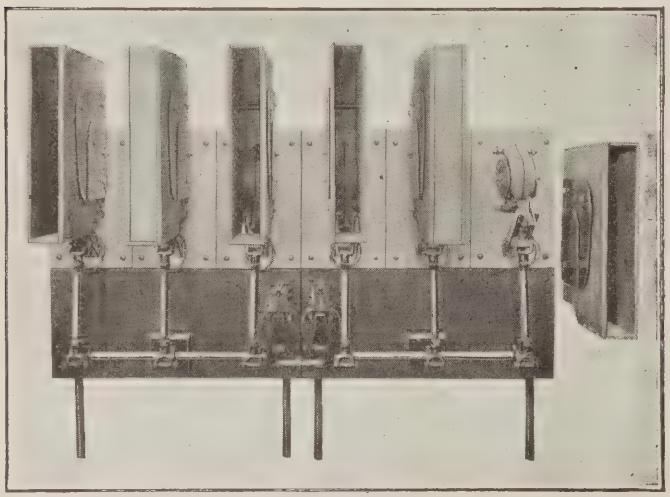

FIG. 9. CONTACTOR PANEL OF WATER HOIST

one of these was read before the American Institute of Mining Engineers and was published in the Mar. 23, 1918, issue of *Coal Age* under the title of "Economy of Electricity Over Steam for Colliery Power Purposes," by R. E. Hobart, Mechanical Superintendent of the Lehigh Coal and Navigation Co. This experiment shows a notable saving effected by the use of electricity over steam in hoisting and pumping at the Rahn colliery. Doubtless this first-hand evidence so strengthened the opinions expressed by other engineers as to the great advantage of electricity, that the Lehigh Coal and Navigation Co. settled on a policy of electrical development. Other changes of policy have also developed as the merits of various devices have become prominent as a result of recent improvements.

In view of the foregoing statement it is not surprising that the Lehigh Coal and Navigation Co. has decided not to continue with the water hoists as in the past. This company considers that water hoists are preferable to steam pumps, but claims that with the conditions at its operations electric pumps do the work better and cheaper than any other method of unwatering its mines.

Low-speed centrifugal pumps have been used at Lansford for four years without repairs—a number of points have been worked out by this company which makes these pumps particularly valuable for its special service. Both steam and electric apparatus have troubles peculiar to each, but the weekly reports of the Lehigh Coal and Navigation Co. show that the electric machines give only half the trouble that steam types do.

The new electric hoist would not have been installed at shaft No. 14 except for the fact of the shaft being ready for it. Furthermore, a steam hoist would have necessitated enlarging the local boiler plant, which would have been inconsistent with an electrical policy. Of course, the water hoists include valuable equipment in engines, etc., and it is not the intention to scrap them and put in pumps at once. They are to be retained to serve the purpose for which they were installed—some of them may be efficient for 10 to 15 years. But in planning for the future and in new development work, it is expected to gradually install electric pumps. Acid mine water does not have the terrors for operators which it did formerly, as it is now overcome by some form of bronze or other acid-resisting metal. Also fine coal and grit, so destructive to the vanes of centrifugals and the valves of triplex pumps, is readily removed by a series of catch basins so that practically clear water runs through the pumps.

From the improvements made in the mechanical end of the coal proposition we might judge that mining was entirely subordinate. As a matter of fact few radical changes have been made in the actual mining of coal for many years. All the developments looking to lowering the cost of coal on cars for shipment are connected with the mechanical end. Better haulage, pumping, undercutting and drilling coal, minimizing breakage from the face to railroad car, all are mainly due to the mechanical engineer. The mining engineer has hardly kept pace with his brother at arms. There are some notable exceptions in the successful treatment of local difficulties, prominent among which are the Lehigh Coal and Navigation Co.'s methods of working its abnormally thick Mammoth seam.

For the assistance given in the gathering of material, both for text and illustrations, used in the preparation of this article, the writer takes great pleasure in acknowledging the courtesy of the officials of the Lehigh Coal and Navigation Co. Also similar thanks are extended to the manufacturers of apparatus described.

Can Dry Coal Without Distillation

Driers are now manufactured which are able to eliminate moisture without distilling any of the volatile combustible matter in the coal; they are fired by hand or with pulverized fuel. The heat first surrounds the shell of the drier, being confined within a chamber where complete combustion takes place; the heated gases are then led through a duct to the discharge end of the drier and enter the inside of the shell at a temperature not exceeding 300 deg. F. This temperature is maintained by the operator and is indicated by a pyrometer. Volatile combustible matter is not likely to be distilled until the temperature rises above 400 deg F.—*H. H. Collins in paper to be presented September, 1918, to American Institute of Mining Engineers.*

Exhaust-Steam Turbine Installations at Coal Mines—II

By E. I. ROBERTS
Cardiff, Alberta

SYNOPSIS—*With an exhaust-pressure turbine it is of course necessary to install a condenser. The choice of condensing equipment depends largely upon local conditions. Surface and jet condensers each have their particular advantages. If the supply of circulating water is not copious, it is sometimes necessary to install either cooling towers or spray ponds.*

WE WILL now consider the means for taking care of the fluctuation of exhaust from the hoist engine, the same considerations will apply to any other units which operate on a fluctuating or intermittent load. If we do not make such a provision, all of the steam above that which the turbine is taking, at the time, will be discharged into the air and wasted; and when the hoist stops running the turbine will then be forced to draw upon live steam to carry the load.

There are two ways of taking care of the steam-quantity fluctuation: One by means of a tank, moving vertically between guides on the gasometer principle, and the other by the absorption of the steam in water in a stationary tank called a regenerator.

In the gasometer method the steam enters the tank at the bottom and at a predetermined back pressure the tank rises. The tank is usually water-sealed and provided with a relief valve, so that if an excess of exhaust steam is made, over and above that taken care of by the gasometer tank, it will exhaust into the air. As the steam quantity becomes less the tank lowers and sends this surplus steam to the turbine. While such tanks are efficient, this method has not yet been used to a great extent on this continent, probably because of its high first cost.

The regenerator method depends on the principle that as the temperature of water is increased over 212 deg. F. it absorbs certain quantities of steam in proportion to the heat increase. The law follows the formula:

$$\text{Quantity of water for storing steam in pounds} = \frac{\text{Total quantity of steam in pounds} \times \text{average latent heat of steam}}{\text{Temperature of steam at highest gage pressure—temperature of steam at lowest gage pressure}}$$

Assuming that the total quantity to be stored is 680 lb. of steam and the highest gage pressure is 4 lb. per square inch and the lowest 0 lb. per square inch, the quantity of water theoretically necessary to store this heat would be 26 tons.

In the Rateau regenerator this intimate mixing of the steam that is necessary for the proper heat absorption is carried on through perforated mixing tubes which extend the full length of the tank. The perforations are small and are all a few inches below the water level. Thus as the steam bubbles through these perforations a circulating current is produced which brings new water in contact with the steam as it enters. This absorbed steam is again given off when the pressure is reduced in the main leading to the turbine. As the regenerator is fitted with a dome, and also as its action is such as to drain all condensed water from the steam, the steam becomes dry and saturated and usually contains less than 1 per cent. of moisture. This feature is important as at the high velocities of turbine blading small quantities of water erode the blades.

We will now consider a regenerator for the hoist outlined above. The regenerator is to be used in connection with a twin 24 x 36-in. simple noncondensing engine (hoisting) discharging an average of 12,000 lb. of steam per hour. The engine averages three trips per minute and the steam inflow is for 6 sec. per trip. The exhaust of the engine reaches a maximum rate of 650 lb. of steam per minute for 6 sec., and no steam for 14 sec. The regenerator is then to receive steam at the average rate of 10.8 lb. per second for 6 sec.—that is, 64.8 lb. during the hoisting cycle. In 20 sec. approximately 65 lb. of steam enters the regenerator, or with three complete hoists per minute the regenerator will receive 195 lb. of steam.

Conditions Influencing Choice of Installation

A regenerator for this duty will be approximately 9 ft. in diameter and 25 ft. long. It will discharge in a steady flux the steam it receives under the foregoing conditions, providing that the pressure is permitted to drop from 4-lb. gage to 0-lb. gage. A relief valve, inlet and outlet connections, gage glass, water filling and overflow connections and water regulating floats and valves should be furnished complete with the regenerator.

Several conditions enter into the choice of types of condensers and auxiliaries. Of first importance is the cooling water, which should be plentiful, pure, and of normal temperature. Preferably the supply should be close to the plant. There should be no possibility of water famine. The feed-water for boilers is the next consideration. This, as is well known, should have no scale-forming impurities, for it means an increased cost for generating power, of 15 per cent. with $\frac{1}{16}$ in. of scale, and as much as 70 per cent. with $\frac{1}{2}$ in. of scale. This latter thickness is not at all unusual around plants using mine water. Of course, these percentages vary with the boiler area that is covered by scale and also the quality of scale. In any case the fuel costs are excessive.

If surface condensers are installed, for the purpose of returning the water to the boilers, provision must be made for extracting the oil from the exhaust steam before it reaches the condenser. This is best done with

exhaust steam oil separators, which are guaranteed to extract as much as 95 per cent. of the oil from the steam, and as much as 97 per cent. in other cases, particularly when the separators are properly cleaned. These separators should not be placed within 5 ft. of any elbow, valve or other arrangement that would prevent a straight, uniform flow to the separator, as the efficiency is much reduced when the steam contains too many eddy currents.

There are two general types of condensers—the jet and the surface condenser. The former intimately mixes the steam and water and the latter keeps separate the cooling element from the steam with a thin metal wall. The jet condenser, because of the mixing method of causing a vacuum, throws away the condensate; and the boiler feed in consequence must be taken from the main source of supply. Further, if precautions are not taken with the jet type of condenser, there is the possibility of flooding the condenser and turbine, should a stoppage occur at the pumps. There are, to be sure, the high-level and low-level jet condensers, but we consider that under the usual mine conditions in the low-level jet condenser is most suitable. There are several types of low-level jet condensers on the market. One of the simplest is the Rees roturbo jet condenser, which occupies a small space and may be direct-connected to an electric motor or driven by a small turbine through reduction gears.

Should the main source of water-supply be reasonably free from impurities, the jet condenser has several advantages over the surface condenser. Among these are lower first cost, lower maintenance, less space and the advantage of being able to use mine water and, under certain conditions, dependent upon the class of boiler fuel used and its cost, it is cheaper for 9-hour-per-day loads than is the surface condenser.

The disadvantages of jet condensers are that they require about 40 per cent. more power to operate than do the surface condenser auxiliaries; this is due to the jet condenser handling more air and also having to discharge against the atmosphere. The condensate is thrown away and its heat lost, the consequent use of only moderately pure feed-water causing boiler scale and consequent cleaning. There is also danger of flooding the condenser and turbine. The surface condenser is suitable where the cooling water is not adaptable for boiler feed, but contains no acid. If it is acidulous it would be cheaper to neutralize it and use a jet type of condenser than to replace surface condenser tubes continuously.

The amount of circulating water necessary is usually more than that required by a jet condenser, but as the head through the surface condenser is not usually more than 15 ft. (this presupposes tubes not corroded) the power required for circulating purposes is less.

Baffles in the surface condenser for the purpose of making the steam take a course close to the cooling tubes, should not be used unless the frictional resistance is less than $\frac{1}{10}$ in. of mercury. Besides the circulating pump an air pump and a condensate pump are necessary. The air pump is used to remove the air that is entrained in the steam or what enters the system through leaks. A small quantity of air in the condenser makes a decided difference in the vacuum. Thus 5 per cent. of the volume of feed water taken from the pond is air, and assuming that 5 per cent. more is added for leakage in the system, then if the leakage is doubled or made 10 per cent. the decrease in vacuum will roughly be $\frac{1}{2}$ in. of vacuum when the vacuum is between 27 and 29 in. referred to a 30-in. barometer. Thus it is important that the vacuum line be made as short as possible and that air leaks of all sorts are thoroughly stopped.

The condensate pump is necessary for the purpose of taking the water from the hotwell of the surface condenser and delivering it to the feed-water supply of the boilers. This unit must be set lower than the hotwell of the surface condenser.

The advantages of the surface condenser are that less power is necessary for driving the auxiliaries; the condensate may be used for feed water, consequently giving less boiler-cleaning troubles; no danger is present of flooding the turbine; and in case of a good quality of coal being used for firing the boilers the surface condenser is the cheapest, even for 9 hours daily running time, because as much heat as possible is retained in the condensate, and the condensate when fed back to the boilers keeps them free from scale.

The amount of vacuum to be carried by the condenser is important. The temperature of the circulating water, however, places a limit on the vacuum. This is shown in the following example: Assume that the ratio of cooling water to steam condensed is 60 to 1, and a permissible temperature rise of 15 deg. F. is the difference between the intake and discharge connections of the condenser, then with intake temperatures as follows:

At 50 deg. F., the highest theoretical vacuum obtainable is 28.9 in. vacuum
At 60 deg. F., the highest theoretical vacuum obtainable is 28.5 in. vacuum
At 70 deg. F., the highest theoretical vacuum obtainable is 28.0 in. vacuum
At 80 deg. F., the highest theoretical vacuum obtainable is 27.3 in. vacuum
At 90 deg. F., the highest theoretical vacuum obtainable is 26.4 in. vacuum

Suppose, however that we figured we could afford to pump 80 lb. of water for every pound of steam, the following would be the vacuum theoretically obtainable:

At 50 deg. F., we can obtain 29.1 in. vacuum referred to a 30-in. barometer
At 60 deg. F., we can obtain 28.7 in. vacuum referred to a 30-in. barometer
At 70 deg. F., we can obtain 28.4 in. vacuum referred to a 30-in. barometer
At 80 deg. F., we can obtain 27.7 in. vacuum referred to a 30-in. barometer
At 90 deg. F., we can obtain 26.8 in. vacuum referred to a 30-in. barometer

These vacua are never reached in practice since the cooling water never rises fully to the temperature of the vacuum. It is customary to specify the temperature of the water under average summer conditions, when the load around the mine is usually lower than the winter loads. By following this custom we have a much higher vacuum when the loads are heavy and thus utilize the steam to better advantage. This then brings us to the water supply and its cooling. If the plant is adjacent to a river and not too high above the water level to cause an excessive pumping charge, the circulating water may be drawn therefrom. Again, if considerable mine water is being pumped, this can be made to pass through the condenser, and in the event of a surface condenser being used, this may be done without the installation of a circulating pump.

The quantity of circulating water necessary depends on the vacuum carried and will vary from 50 to 100 lb. of water per pound of steam. In the case of the unit under consideration we will assume that the ratio is 60 to 1, which will mean that for 20,000 lb. of steam per hour we shall pump 2400 gal. per minute. Further, assuming an average summer temperature of 80 deg. F. for the water, we can obtain 27 in. vacuum, referred to a 30-in. barometer.

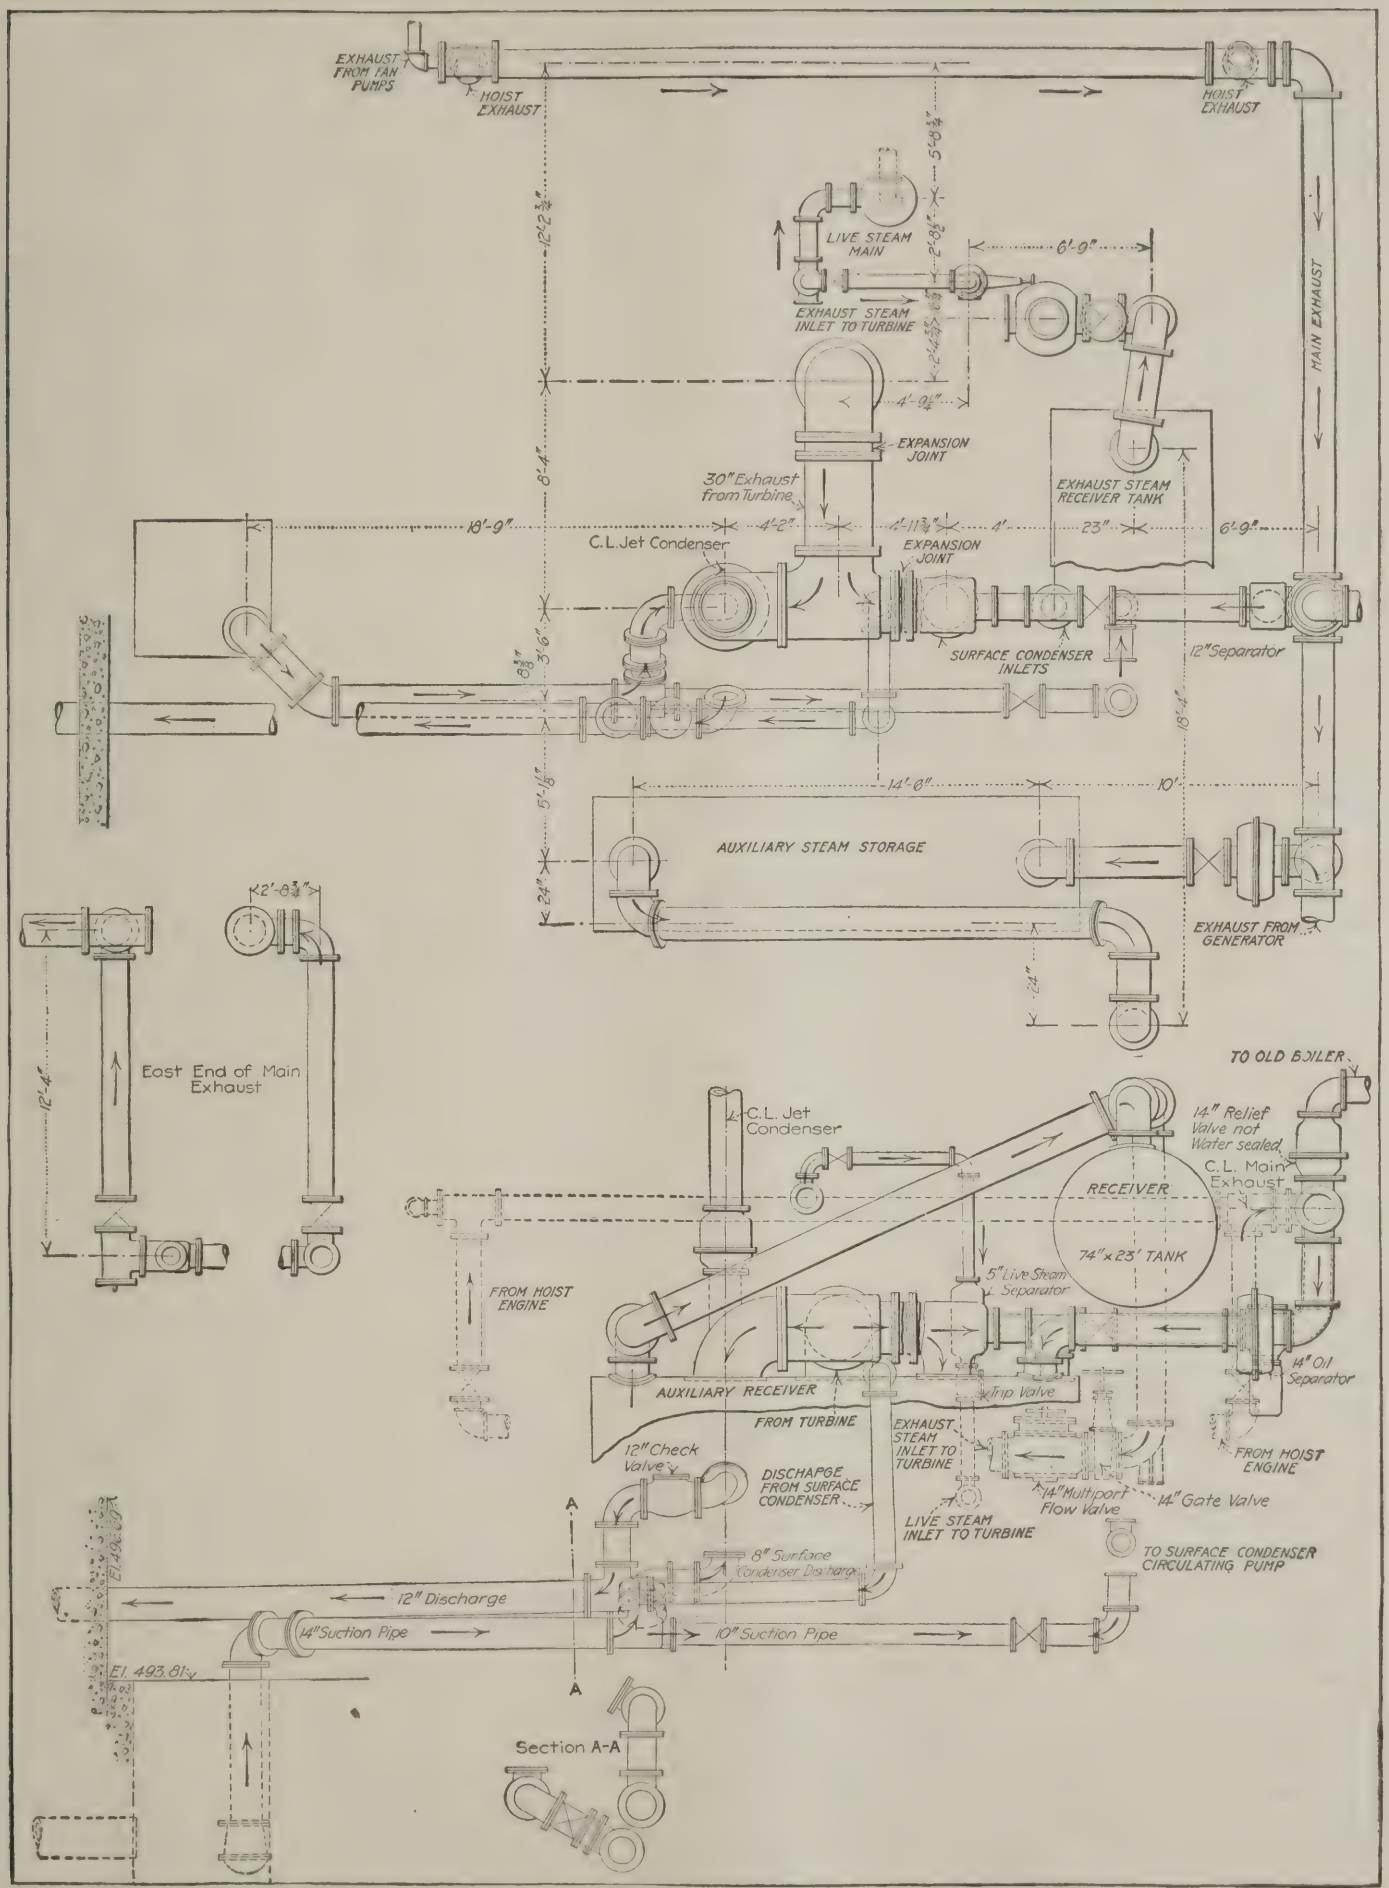

FIG. 3. LAYOUT FOR THE MAIN PIPING OF A 500-KW. EXHAUST STEAM UNIT

The following is a brief draft of specifications covering a surface condenser to comply with the assumed conditions:

1. The condenser is to furnish 27 in. of vacuum, referred to a 30-in. barometer, with 80 deg. F. intake water. The quantity of steam to be handled at full load of turbine is 20,000 lb. per hour.

2. The condenser is to be of the surface type and to work on the "wet system"—that is, to have one pump to handle the air and condensate and another to handle the circulating water.

3. According to the requirements of the coal company the exhaust inlet shall be at the top or at the side of the condenser; these shall be 30 in. in diameter, flanged and drilled with standard drilling.

4. The friction head of the condenser shall not be more than 15 ft. nor less than 5 ft. at the above-mentioned or other normal capacities.

5. Terminal difference is permitted of 15 deg. F. at the full load rating of the condenser.

6. Ample steam space shall be provided near the inlet for steam distribution.

7. Condenser shall be equipped with drain plates, to avoid flooding of tubes by condensation and to insure this reaching the hotwell with the least possible loss in temperature.

8. A heat transmission coëfficient of 300 to 400 B.t.u. per square foot of surface per hour for each degree Fahrenheit difference shall be used in the design of this surface condenser.

9. The design shall be such that the steam shall take the shortest path through the condenser possible; and the frictional resistance through the condenser shall be less than ½ in. mercury.

10. Auxiliaries shall consist of the following: One vacuum pump of rotary design for air and condensate; one centrifugal circulating pump, 30-ft. head; one steam-driven unit, turbine preferred, taking 100-lb. gage pressure, live saturated steam, noncondensing, all to be mounted on one base, direct-connected or through reduction gears; one 30-in. gate valve, for placing between turbine and condenser; one 30-in. corrugated expansion joint; one 14-in. atmospheric relief valve, multiport type preferred.

In the absence of a river or lake of water of sufficient capacity to supply the condenser and keep the water cool, or when little mine water is handled, cooling towers or sprays will have to be used for cooling purposes. Such devices permit the circulating water to be used over and over because the heat is extracted by either one of these methods.

With towers, the water is cooled chiefly by evaporation, which absorbs 75 to 85 per cent. of the heat, while convection and radiation absorbs the balance. This is accomplished by bringing a sufficient quantity of air in contact with the circulating water broken up into fine sprays. The quantity of water evaporated will equal about 75 to 85 per cent. of the weight of the steam passing through the turbine, and this loss must be replaced by a fresh supply.

Cooling towers are of two types—the natural draft and the forced draft.

The first method of cooling depends on air circulating naturally in and through an open tower. The latter method depends upon a fan forcing a certain quantity of air through a closed tower. The other method of cooling is by spraying. The spraying apparatus consists of several banks of nozzles, discharging the water into the air in fine, globular particles, and as these fine particles fall to the pond beneath an intimate contact is made with the air, which absorbs the heat taken up in passing through the condenser. The pressure necessary to make the spray varies according to the coolness of the weather. In summer it may be as high as 15 lb. per square inch and in winter as low as 3 lb. per square inch. Because of evaporation and drifting caused by breezes, etc., from 1 to 3 per cent. of make-up water will have to be added. Under general conditions with a well designed pond this is less than 1½ per cent.

Considering the 500-kw. plant which we are contemplating, the spray cooling system necessary will be as follows: Assuming 30 gal. of water per minute for every 2-in. nozzle, with an $\frac{11}{16}$ in. diameter opening, 80 nozzles should be sufficient. However, for the purpose of replacement and additional cooling, we will assume that eight more nozzles are installed, making a total of 88. The size of pond necessary for these nozzles will be approximately 1 sq.ft. for every 100 lb. of water cooled per hour, or in this case 12,000 sq.ft. This assumes that the nozzles are placed four in each group and the groups on 20-ft. centers. At least 20 ft. should be allowed, also, between the centers of the nozzles and the side of the pond. If the area available does not permit this, a fence will have to be constructed to prevent excessive water drift. The pond need not be deeper than 3 ft., but there should be a slight drainage toward the cold well. The power consumed by sprays varies from 0.75 per cent. of the turbine power at low heads to 2 per cent. of the turbine power at high heads. This power then has to be taken into consideration with the circulating pumps and their driving arrangements when the condensers are specified.

Power Consumed by Low-Level Jet Condenser

The amount of power consumed by a low-level jet condenser varies from 5 to 8 per cent. for units of from 200-kw. to 500-kw., and the power used by auxiliaries for surface condensers varies from 0.75 hp. to 1 hp. for every 1000 lb. of steam per hour passing through the main unit, for circulating pumps. The amount of this power is governed by the head. The figure given is for 20-ft. head and 70 per cent. efficiency. The air pump requires from 0.20 hp. to 0.5 hp. per 1000 lb. of steam, and the condensate pump, depending upon the head, from 0.07 hp. to 0.15 hp. per 1000 lb. of steam.

It is preferable that small turbines or other steam-driven units be used for the driving of auxiliaries, for although motors may be used to operate pumps, etc., and are connected up behind the circuit breakers, there is always a danger of something stopping the unit. Furthermore, if motors are used, they must be started by a separate generator, and it is preferable that they be driven by a separate generator entirely if the turbine is to carry the mine load. By studying the chart (Fig. 2, page 1050, *Coal Age*, June 8, 1918) it will be noticed that the vacuum varied as much as 1 in., partly because of the steam admission but chiefly arising from the variation in the speed of the motor, which was driven by the turbine. This unit was later connected up and driven by a separate generator, one not operating on a fluctuating load, and a much steadier vacuum resulted.

The space occupied by a unit of this size with condenser, auxiliaries, etc., with top exhaust from the turbine to the condenser, and the condenser set at the side of the turbine, will be approximately 24 ft. wide and 40 ft. long, including a passageway and room for a switchboard.

The steam connections for the usual unit will consist

of exhaust steam piping, vacuum piping, circulating water piping, drains and traps. Mixed pressure turbines will in addition require live-steam piping, and a surface condenser installation will require air and condensate piping.

For the exhaust-steam connection a pipe the same size as the turbine inlet should be used from the regenerator to the turbine, and an expansion joint of corrugated sheet copper, about one diameter in length between flanges, fastened to this inlet to take all pipe and expansion stresses off the turbine casing. Next to the expansion joint it is usually advisable to install a multiport flow valve, to prevent the vacuum backing up on the exhaust-steam main and drawing air through minute leaks. No. 10 or No. 12 gage spiral riveted pipe is possibly the cheapest to use for exhaust purposes, but the larger sized pipe—10 or 12 in. diameter—should not be allowed to carry more than 4 lb. per sq.in. pressure. A relief valve, preferably of the multiport type, should be installed either in the exhaust main or at the regenerator to prevent more than this pressure causing damage to the exhaust mains. The regenerator should be placed as near as possible to the turbine so that the driest steam available will be used in this machine. In the absence of a regenerator a large receiver should be used, so as to extract all water from the exhaust steam. A trap of ample capacity should take the water from this receiver, and if an oil separator has been installed to extract the cylinder oil from the steam before it reaches the receiver this condensed water may be returned to the heater or source of boiler feed.

The vacuum piping should be designed and installed with the greatest care. A loss of but ½ lb. through friction in the pipe line means a loss of 1 in. vacuum at the turbine, and as 120 to 130 cu. ft. of steam passes through the vacuum line for every cubic foot passing through the live-steam line, the reason for large vacuum lines is obvious.

It is also extremely important that these connections be short and have few bends and obstacles. For as explained previously the loss of 1 in. of vacuum, say from 28 to 27 in. of mercury at the turbine, will mean an increase of 7 per cent. in the steam consumption for the same power. This increase, although made on exhaust steam—that is, as it were, recovered for nothing—still means a definite loss per annum.

Construction Details of Vacuum Piping

The vacuum pipe may be made from riveted steel pipe, cast iron or regular welded steel pipe. The flanges, however, should be made of wrought iron or cast steel. The gaskets should be made from adhesive gum, as this softens with the heat and sticks to the flanges, thus preventing the gasket being drawn in by the vacuum. If valves are necessary, they should be of the gate type and of standard size, to prevent warping under continued vacuum. A water-sealed relief valve, preferably of the multiport type, should be installed at some point in the vacuum line between the turbine and condenser, but does not have to be larger in size than the exhaust steam inlet into the turbine.

It is preferable to so install the vacuum line that there shall be no low spots or pockets for the accumulation of condensed steam. Where this cannot be avoided vacuum traps will have to be used; as a general rule, however, vacuum traps are a decided nuisance and require constant attention. It is important that the expansion joint in the vacuum line be placed in such a manner that the vacuum does not tend to draw the condenser and turbine together. In one plant with which I am familiar, for several months a bad vibration was noticed in the turbine. It was ultimately found to be due to the vacuum tending to draw the turbine toward the condenser and thus throwing a decided stress on the turbine casing. Long bolts were inserted in this expansion joint to limit the travel of the piping on expanding, and no further vibration occurred. When connected up the vacuum line should be tested with the highest vacuum possible, and while the vacuum is still on the line, two applications of thick paint or hot pitch should be applied on all joints, and at least one coat of paint over the entire piping carrying vacuum, so that all minute air leaks may be properly stopped.

Intake Piping for Circulating Water

For the circulating water the intake piping will first be considered. As a general rule the pond is at some distance from the turbine site, and the intake piping has to be buried. It is not absolutely necessary that pipe be used for this waterway, for in the majority of cases the intake is of such size that it would ultimately be cheaper to use wooden casing, tile pipe or concrete, particularly if the entire conduit is below the usual water level of the pond. If this intake is longer than 200 ft., wells should be placed every 100 ft., and the height of the waterway should be such that a man can walk easily in it, even if there is a foot or two of sand at the bottom. Concrete is probably the best material to use for the intakes since the life of metal pipe when buried is short. Of all the cheaper metals cast iron has the longest life, and if this can be procured at a moderate figure it is wise to use it.

Whatever the construction of the intake may be, it is necessary to guard its mouth so that the entrance of leaves, sticks, fish, ice, logs, etc., is prevented. To do this screens of different mesh must be used, so arranged that they can easily be removed for cleaning. Provision must also be made for closing off the intake line from the pond, so that the cleaning of the intake may be properly done. The suction lines from the cold well must be installed with considerable care, fitted with foot valves and tested for leaks. These lines should also be provided with vacuum gages, so that trouble can be detected at once. The importance is readily seen for having the condenser set as near the water level as possible, so that the water is not elevated more than absolutely necessary.

For the discharge piping, it is important, in the case of a surface condenser, that the discharge connection be at the same elevation as the intake. The condenser should not be burdened with friction other than that caused by the water in the tubes, passageways, etc., which cannot be avoided. If the discharge piping is also placed under ground, the remarks that have been made concerning the intake will also apply here. In cases where oil separators are not installed to extract the grease from the steam, oil catchers should be placed at the mouth of the discharge to prevent the oil going into the pond, and afterward being drawn in with the feed water.

The air and condensate piping is subject to the same

provisions as the vacuum piping, and if leaks are present they may be located in the following manner: The line may be filled with water at a pressure of about 10 lb. per sq.in., and while the piping is full and under this pressure a thorough inspection should be made of the entire system. In cases where the vacuum piping is subject to this water pressure, extra supports should be placed under the piping to take care of the weight of water in the system, which in large piping, such as is usually used for turbines, would make an excessive weight on the permanent supports. If gas is available near the plant, the piping may be filled with it, testing for leaks with a candle. To fill the system with gas it is necessary to fill it first with steam, then close up the line, and as the steam condenses permit the piping to fill with the gas.

The condensate may be sent back to the open heater and then fed in the usual manner through the feed pumps to the boilers. In the case of a closed heater the condensate may be fed from the pump to the boilers.

All exhaust piping, live-steam lines and tanks should be covered with pipe covering. At 3 lb. back pressure per square inch, and 70 deg. F. room temperature, the steam condenses at the rate of 0.47 lb. per sq.ft. per hour. If 10-in. pipe is used and it is 100 ft. long, 135 lb. of steam will be condensed per hour if pipe is without covering. At 8000 ft. per minute velocity a 10-in. pipe will carry 9000 lbs. of steam per hour, and with the loss mentioned it means that 1½ per cent. of the steam is wasted in this length of piping alone.

In Fig. 3 is shown the main piping of a 500-kw. exhaust steam unit. Provision is made for the installation of both a surface and a jet condenser, each of sufficient size to carry the turbine itself. This arrangement was made so that at certain times in the year the mine water could be used, and at all other times the surface condenser would be operated. The surface condenser also is run at a reduced capacity at night, in order to save all of the exhaust steam, returning the condensed water to the heater. As deliveries would not be promised at an early date on regenerators, the tank, an old boiler, shown on the drawing, was used temporarily for storage purposes. The regenerator, when installed, was placed just outside of the building, and to avoid too much heat loss was covered with magnesia.

The costs for a 500-kw. unit will be approximately as follows:

	Per Kilowatt
Turbine and generator on its foundation	$25 to $30
Condenser and auxiliaries	10 to 12
Regenerator	6 to 7
Piping and fittings	6 to 7
Erection and installation of complete unit	5 to 7
Total cost of installation	$52 to $63
Operating Charges:	
Fixed charges—5 per cent. interest and 8 per cent. depreciation	$6.76 to $8.19
Oil, waste and other supplies	.60 to .90
Attendance, if necessary	2.00 to 3.00
Total annual cost	$9.36 to $12.09

As a general rule extra attendance is not necessary, as this unit is either placed in a building with other units or the old generators are dispensed with and their attendant takes care of the turbine. Assuming then that an attendant is an extra cost, and that the power factor is 80 per cent. of the full load, and that the turbine is operated for 9 hours for 250 days per annum, the cost per kilowatt-hour to the company will be from 0.52 cents to 0.672 cents per kilowatt-hour.

Disastrous Mine Fire at Villa

The mine of the Mill Creek Cannel Coal Co., at Villa, W. Va., took fire about 2 p.m. Monday, May 20, following what is believed to have been an explosion of the gasoline engine by which the mine fan was propelled. Thirteen men lost their lives, and much damage was done to the mine. Villa is a small town about 10 miles north of Charleston. Both the gasoline engine and the fan for which it generated power were located within the mine.

The chief inspector of mines at Charleston was promptly notified, but in the absence of a fan and other safety equipment for rescue work it was found impossible on the first night to make much progress in the exploration of the mine, as the cannel coal was burning fiercely. A fan from the mines of the Lebow Brothers, at Big Chimney, eight miles north of Villa, was brought to the burning mine. By Tuesday morning the fan had been placed in operation. Sometimes it was used to suck out the smoke and at other times to pump air into the mine. It was hoped that enough air might be supplied to save the 13 imprisoned miners. A line of hose was laid to the mines and a stream of water pumped into the drift in an effort to localize, as far as possible, the fire raging within.

In its efforts to extinguish the fire and to reach the men imprisoned, the State Mine Department was aided by the Federal rescue car, which reached Villa early Wednesday morning. Owing to the fire it was not till late that morning that the rescue party, headed by Chief Heatherman and State Inspectors Zach Evans, W. B. Riggleman, Eli Mason and B. S. Buckner, mine boss, and James Martin, superintendent for the Laing coal interests, were able to penetrate any distance into the mine. In a chamber about 400 ft. inside the mine they discovered the bodies of nine miners who, in an effort to brattice themselves in, had succeeded in building a wall of dirt and other material within a foot of the top of the tunnel. Conditions tended to indicate that all had died soon after the fire started.

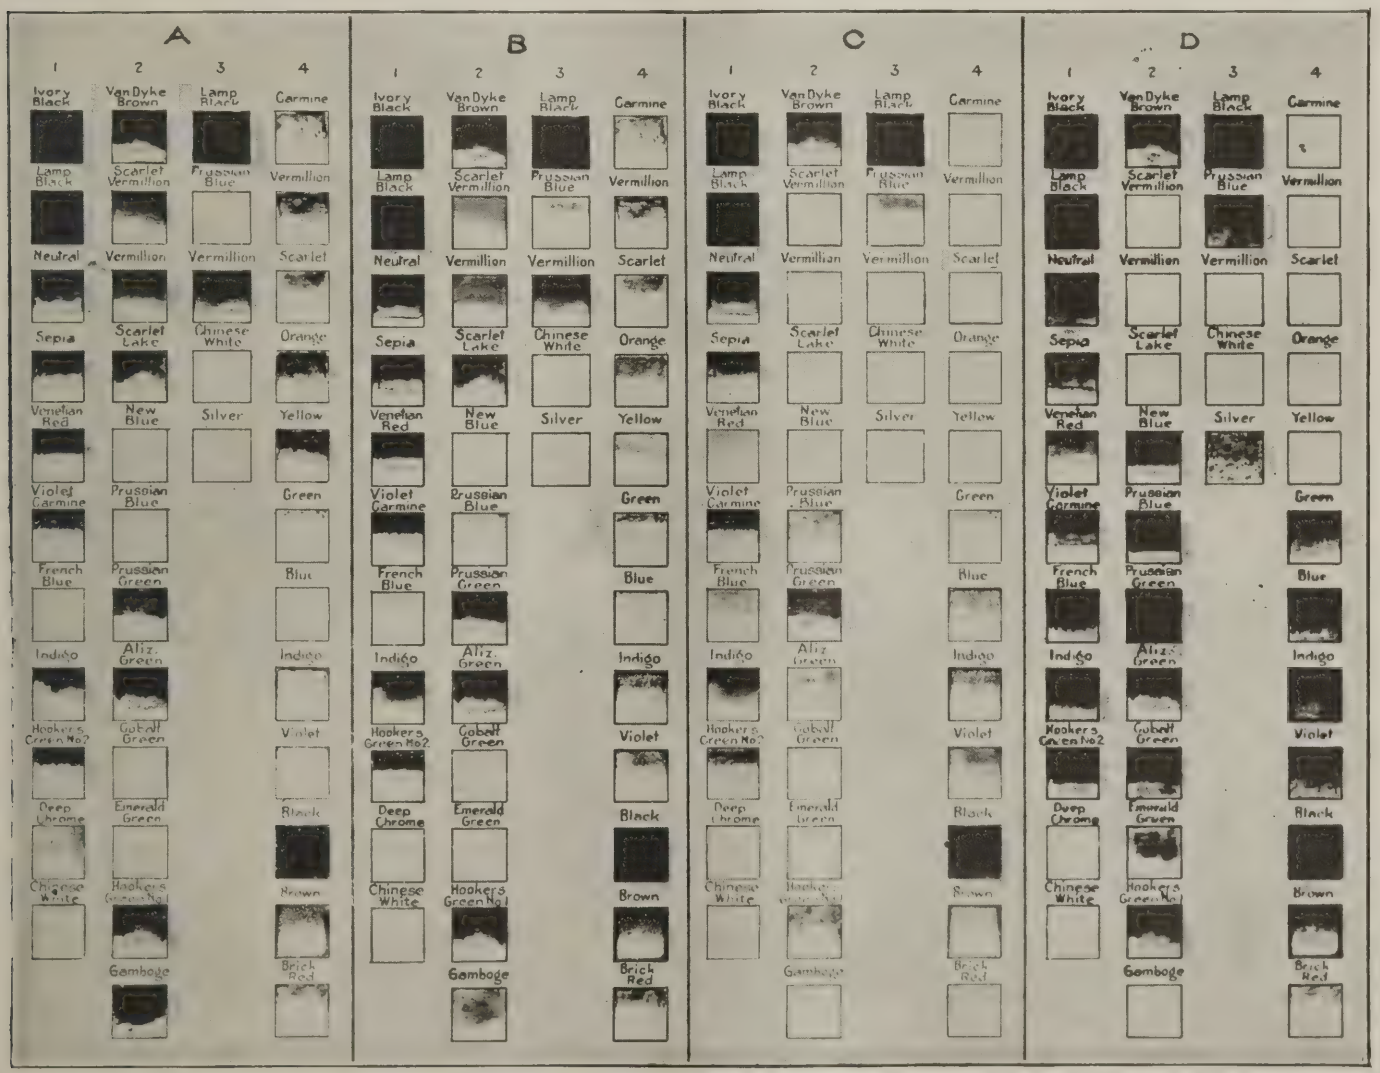
The Mill Creek Cannel Coal Co., which operates the mine at Villa, is a Cleveland, Ohio, concern, J. L. Deegans being its president and general manager; F. M. Wattles is its vice president and B. R. Taylor its secretary and treasurer. The mines at Villa have been operating in a 3-ft. seam of cannel for 19 or 20 years, and they are among the oldest of the plants in the field in which they are located. The output of this particular operation is about 700 tons a month. Having had an opportunity to inspect the mine at first hand as the leader of the rescue party, Mine Chief Heatherman has been very severe in his criticism of the way in which the mine has been operated. He declares that it has been conducted in disregard of the fundamental principles of safety.

It seems that most mechanical stokers are smokeless not because they burn the smoke, but because they burn the coal in such a way that very little soot or smoke is produced. Hand-fired furnaces are smoky because soot is produced in or near the fuel bed, and can not be burned in the limited combustion space of the furnace.—*Bureau of Mines Bulletin No. 135.*

Coal Mine Photography—II

By H. A. WILLIAMSON
Fairmont, W. Va.

SYNOPSIS—*Various shades possess various actinic powers. By proper intensification shades actinically weak may be brought into prominence, or any color or combination of colors may be brought out while other tints may be rendered neutral. Thus by the aid of the camera and suitable screens one map may be made to serve several purposes.*



IN THE production of maps, particularly those made on tracing cloth or paper, little or nothing is to be gained, except in rare instances, by the use of other than black ink. It is not usually possible for more than a few people interested to see the original map, and blue or other prints made from the original do not show the colors. Errors are frequently made in using various colors, by getting a line in the wrong shade; and in many cases colors are more confusing to the eye than the simple black.

There are times, however, when it is essential to use various tints on a map, and it is necessary for the mapmaker to know the relative photographic value of colors if the maps are to be used in connection with photographic work.

The accompanying illustrations show the result of photographing various colors commonly in use in drafting rooms. With the exception of the blacks, which are laid on solid, these colors are made heavy at the top and shaded lighter toward the bottom in order to show the variation in value between a color heavily laid on and a thin wash.

Chart *A* represents the results of the use of an ordinary contrast, or commercial, plate. Chart *B* is from a panchromatic process plate. Chart *C* is from a panchromatic process plate and a light yellow screen, or ray filter. Chart *D* is from a panchromatic process plate with a bright red screen.

On each chart, column 1 consists of standard pan water colors, which are opaque in character; that is, they obliterate anything over which they are laid. Column 2 is shaded with standard pan water colors, translucent in character, or which do not entirely obliterate other

THE RESULT OF PHOTOGRAPHING VARIOUS COLORS WITH VARIOUS PLATES AND SCREENS

colors beneath them. Column 3 consists of special liquid water colors for drafting-room use. Column 4 is colored with standard "waterproof" inks for drafting-room use.

In general it may be said that blues and greens have the least effect on a photographic plate, while reds and oranges have the greatest. Thus a yellow or brown consisting largely of blue (a cold color) will have little effect on a plate, while a yellow or brown consisting largely of red (a warm color) will have great effect.

There are commonly in use seven screens—yellow, orange, orange-red, bright red, dark red, green and blue. The four charts, however, will serve to illustrate the purpose of these screens or filters. The orange and orange-red screens are intermediates between the yellow and bright red, and the dark red goes beyond the bright red. The blue and green screens perform exactly the opposite duties to the red screens; that is, where the red screen intensifies greens and blues, the green and blue screens intensify reds and yellows and cut out the greens and blues.

From these charts the draftsman can select the colors best suited for his maps. It is immediately noted that on all the plates the drawing inks do not have anything like the value of the water colors; yet, on the other hand, water colors are much more difficult of preparation in quantity, and it is therefore necessary to use the inks except in special cases. It is also true that no matter what plate or what screen is used, black ink and black water colors have practically the same effect.

The charts show, for instance, that it is possible to make a map lettered and showing political features in black ink, showing streams with indigo or violet ink, contours with brown and other features with scarlet, orange or yellow. From this map then, by the use of a proper plate and suitable screen, a reproduction may be obtained showing all the features, or those features in black, and any particular one of the others made prominent, with the balance eliminated. Thus from the same map we may have a plate showing political features and streams only; another showing political subdivisions and contours; one showing political features and triangulation, and so on in variety to meet the needs.

In order to successfully photograph a blueprint, one has only to use a panchromatic plate and red screen. Conversely, should you have a valuable map on which a bottle of red ink had been spilled, a plate which will show no indication of the blot may be obtained by using a proper plate and red screen.

It is not possible, in an article such as this, to more than point out a few of the possibilities along the lines indicated, but the interested draftsman can obtain extremely valuable detail literature from any of the large dry-plate manufacturers on the use of panchromatic and trichromatic plates and color screens (color screens are often called ray filters). The reader is also referred to the first installment of this article and to the article on the "Camera vs. the Pantograph," which appeared in the *Colliery Engineer*, January, 1915.

(To be continued)

Care and Management of Coal Cutters

By "MACHINE MAN"
Sullivan, Ind.

THE proper care and operation of electric coal-cutting machines play an important part in deciding the cost of production at any colliery where these machines are used. Supplies are hard to get at present, and air-ship prices prevail in everything manufactured of iron, steel, brass or copper. These four materials, together with a little carbon, mica and rubber insulation, compose a coal-cutting machine. When properly cared for, however, such a machine is a great help to larger production, as a man can load about one-third to one-half more machine coal than pick coal.

It seems to me that a great deal of the efficiency of coal-cutting machines depends in a large measure on the efficiency of the machine men and electricians who look after them. I have been employed on machines for the past 10 years, both as helper and runner, and during that time I have seen men working on machines who had all the chance in the world to cut a large quantity of coal, but whose tonnage was low. If I were an employer, I would take two good machine men and a poor machine in preference to a good machine and two poor machine men.

The most important item in the economical cutting of coal is to keep the machine in good running condition. This is where the poor and inexperienced men fall down and heap up the repair cost. An inexperienced man should never be permitted to work as a runner on a machine. It is better to let the machine stand idle. Such a man will work a few days, and work hard, but he does not possess sufficient knowledge to successfully operate the machine. He becomes disgusted and quits, leaving the machine in a run-down condition, which will be a detriment to the hiring of a man capable of handling it. As a general rule a man wants to see the machine before he takes a job to run it, and it is hard to get a qualified man to take a machine that he knows is run down and not in proper shape to do the work required of it. This is even more so now than heretofore, on account of the scarcity of labor.

Much hard feeling is caused among miners because of the machines. Every man wants a trial on the machine as it pays a little better than other mine work. But every man is not mechanically inclined and many could never make successful machine men.

In some cases the electrician or machine boss is to blame for hiring incompetent men, while at other times the mine management is at fault. In some instances the machine man is to blame. I have known of cases where men who were fairly competent to operate machines would deliberately tear them up owing to some trifling difference which had arisen between them and the mine management or electrician. When the mine management is to blame it is generally a family or pet affair. As a general rule the foreman has some close friends or relatives. These naturally look to him to be favored with a good job, and in

nearly every instance influence him until they get it. If it is a machine they want, it is given them, and in a great majority of cases they fail on account of insufficient mechanical ability.

Where the electrician falls down is in hiring strangers. They come to him with a good recommendation, possibly given by some one who had never seen a machine. He hires them, as he is pressed for good machine men. In some cases they prove to be O.K., but a large percentage fail.

I believe a stranger should always be hired on condition—on probation, so to speak. Let the electrician go with him and watch him cut a few places. A poor man can be detected at once when at work. If he can't get around and keep things humming, he should be given a job at something else in the mine.

A mining machine is built to stand a great deal of abuse, but the less mistreatment you give it the better off you are both physically and financially. Before starting to work in the morning the runner should go over the machine and oil every bearing and examine all nuts, chains, etc., for loose or broken parts. If any are found, they should be repaired before starting. If only some small nut or rivet is loose, this can usually be remedied by the machine man quicker than he can get the electrician. But let me emphasize again that any difficulty of this kind should be rectified before starting the machine on an 8-hour grind.

Electrician Only Should Rectify Electrical Troubles

If some electrical part is not in working order, the electrician should be summoned in every instance, as this is the most delicate part of a coal-cutting machine. Here is where many men fail who otherwise would be good machine men. If a small nut or bolt breaks, one that is not sufficiently important to stop the operation of the machine entirely, they go ahead and run it, thinking perhaps they haven't time to make repairs just then, expecting to let the electrician know about it that night. Of course this is only a bolt, but it weakens the machine to that extent and perhaps throws double stress on another bolt, which in turn will affect the whole machine.

I have known instances where this very thing has happened—and before night the machine would be laid up for a week or two for repairs. The old saying that "a stitch in time saves nine" proves out in operating machines if in nothing else. Perhaps the fact that a little 5c. or 10c. bolt is gone will cause a piece to break that costs $100 or more and necessitate waiting until the manufacturer sends the piece.

Just figure this out for yourself. Suppose an order will reach the manufacturers and be filled in four days, which is a shorter time than they generally take. Figure the machine at 150 tons per 8-hour shift, which is a low figure if shortwall machines are used. This would be 600 tons in four days lost to the operator and machine man. It means $33.69 in Indiana for each of the machine men and that much, if not more, for the operator. It also means just that much less coal for the support of the factory or railroad to which fuel is being sold. This loss will run into many hundreds of dollars in a year's time in three or four mines.

It seems to me it would be an economical investment for a company operating three or four mines to hire an expert machine man to make the rounds of the mines in turn, spending a day at each mine and doing absolutely nothing but watch the operation of machines and stopping them when he saw that it was necessary for the welfare of a machine. This stoppage would probably also be to the advantage of the machine men and company as well. A man who has successfully operated a coal-cutting machine for five or six years would use better judgment in this position than a shop man or electrician, for such a man knows the weak points of every machine after he sees it run a short time. He might not know the first principles of repairing the defect, but here is where the electrician or shop man should be called upon.

Good sharp bits are essential to the efficient cutting of coal. A machine should never be run after the bits become so dull and rounded on the point that they drag down the speed of the motor, as this only tends to heat the resistance and possibly burn it up. Pick-point bits are better for shortwall machines. If the coal is a little woody and tough, a half dozen chisel points interspersed along the chain are advantageous, as these will knock out the core left in tough coal when using all pick points. I do not think it advisable to use all chisel-point bits in shortwall machines, as they become blunt—or rather the edge becomes rounded—and drag down the speed until the machine men get behind with their cutting and possibly tear up something.

I once worked in a mine where the electrician got it into his "noodle" to use all chisel-point bits. In about three days the machines were so far behind with their cutting that the runners had to come back and cut at night. Furthermore, two bedplates were broken which cost over $100 apiece. Sullivan longwall machines were used in this case, and every drag chain became stretched to such an extent that it was almost impossible to load the machine after a room was cut.

I believe this strengthens my argument that a good machine man knows better what is needed to successfully cut coal than a shop man or electrician. I would like to see other articles in *Coal Age* regarding the care and management of coal-cutting machines, as we all will be helped by an interchange of ideas.

POWER PLANT, ENGINE HOUSE AND TIPPLE AT CHICAGO & CARTERVILLE COAL CO., MINE B, AT HERRIN, ILL.

National Coal Jobbers Hold Convention

SYNOPSIS — *Jobbers meet to discuss the coal situation and their relation to it. Speakers urge necessity for coöperation with Fuel Administration. Excellent addresses made at the banquet which followed first day's session. Wednesday's session witnessed an active discussion of the question of cost reports.*

THE second annual convention of the National Coal Jobbers' Association, which was held in Buffalo on June 4 and 5, was a notable affair. More than 200 members came from all parts of the country to participate in the proceedings, to discuss their status in the coal industry, and to affirm their readiness to coöperate with the Federal Fuel Administration in every way. President E. M. Platt conducted the proceedings with an even hand, and in his opening address recounted the energy with which the work of organization had been carried on.

Organization Making Rapid Strides

Less than nine months ago the association was originally projected at Washington, and since the formal organization at Chicago in October, 1917, the membership has grown to 600—a membership thoroughly representative of the jobbers of the entire country. President Platt pointed out that there is no longer any question raised by the Fuel Administration as to whether the jobber is essential, the association having obtained the complete recognition of the Fuel Administration and established itself firmly as a coördinate branch of the coal industry, with a representative on Dr. Garfield's staff.

The first day's session was made especially valuable and interesting by Noah H. Swayne, 2d, who acted as the Commissioner of the association in Washington and did yeoman's work for it, to the sacrifice of his jobbing business in Philadelphia. Mr. Swayne appeared on the platform several times, first giving a chronology of the proceedings in the coal trade since the Fuel Administration was appointed, then returning to urge the jobbers to furnish reports to the authorities when asked, as these reports were made the basis of intelligent action. Abuses were creeping into the trade, said Mr. Swayne, and instanced the application for jobbers' licenses by men who had no right to them. Many of these applications, continued the speaker, came from producing interests.

In the afternoon Mr. Swayne answered questions from the floor regarding trade regulations, but usually convicted the questioner of not having read the Fuel Administration's bulletins. (At the banquet a speaker made some humorous remarks about Mr. Swayne's ability to quote from these bulletins, now about 40 in number, by page and line.)

Secretary Leo Romanski reported that the association was in good financial standing, and in a later report on the jobbing situation in Chicago asserted that the local fuel administrators in the west were usurping the place of the jobber, who is not being treated fairly. The banquet given Tuesday evening was largely attended. The toastmaster, Harry D. Williams, took a notable part in the speaking, and the addresses made were eminently fitting for the occasion. Vice president William R. Coyle, who is about to return to the marine service, uttered words of counsel and inspiration. He spoke of the interests of producer, distributor and consumer being equal, and urged that all should do their utmost to pull together.

Alfred W. Calloway had come up from Washington to reason with the jobbers, and he told them they ought to coöperate in every possible way with the Fuel Administration, to the end that the most be made of what promises to be an inadequate coal output. He condemned the dirty coal that many operators and jobbers were offering. To mine and distribute this coal was a great waste of time and resources, and it actually curtailed production. The utmost effort must be made to keep production from falling off. Another draft was near, and it would carry off many men. He believed that working hours must soon be regulated by authority. Mr. Calloway does not like the word "jobber," and suggested that the name of the body be changed to National Association of Coal Distributors. (The association next day left the decision to the executive committee.)

Francis S. Peabody in an address took up the question of compensation and illustrated his idea by quoting Ralph Waldo Emerson. Mr. Peabody believed that cooperation and loyalty were synonymous. With the other speakers he eulogized Dr. Garfield and said that the latter was loyal to the jobbers. Let us help Dr. Garfield, said Mr. Peabody, and the jobber will receive a just compensation.

Valuable information as to cost reports was imparted at Wednesday's meeting by Jean Paul Muller, of Washington, an expert accountant. He urged the freest and fullest reports. The difficulty so far was that the reports made were not on a uniform basis. The speaker promised that nothing would be made public by the Fuel Administration.

Cost Reports Came in for Much Discussion

There was much discussion of the question of cost reports. It was insisted that the association, as well as the Fuel Administration, ought to know what it cost the jobbers to do business. Mr. Platt stated that the anthracite trade knows to the fraction of a cent what its costs are, while the bituminous jobber knows nothing. Mr. Swayne said that if the bituminous jobber did not function 100 per cent. there would be disaster. The costs should be based on zones. An entering wedge had been obtained in adequate reports from the smithing trade, and the bituminous trade must drive it further. Also, concluded Mr. Swayne, the jobbers need this information for their own self-education.

Officers for the ensuing year were elected as follows: President, George M. Dexter, of New York; vice president, Charles E. Cartwright, of Toledo; secretary and treasurer, Leo Romanski, of Chicago.

A Great Disaster

By Edward Mott Woolley

A great disaster threatens the readers of trade papers. When the new zone system of postal rates goes into effect next July these papers will be affected more than some other kinds of publications, and this means that their readers will suffer heavily by being shut off more or less from this wonderful fund of information.

Trade papers carry a large proportion of advertising and therefore the burden of the postal increase, ranging from 50 to 900 per cent., will fall very heavily on them. Now anyone who uses the trade papers knows that the advertising pages, while published for profit, are read for information just as much as the editorial pages. If the publishers were to eliminate the advertising and print simply articles, what a vacuous magazine we would have! The advertisements reflect the whole industry represented by any given trade publication. In the aggregate the advertisements of all the trade papers stand as the index of American industry. Indeed, the status of each industry is presented in undeniable truthfulness every week or month. Shopkeepers, mechanics and students depend upon these journals for their broader knowledge of the particular industry in which they are engaged.

The ill-advised postal zone law will make it impossible for these trade papers to exist in any such form as they do now. Inevitably they must be curtailed so radically that the benefits we now get from them will be largely wiped out. If you don't want this disaster to fall on you, make the fact so plain to your senators and congressmen that they will repeal this destructive zone law. Write to your Congressman to repeal this destructive and disastrous postal "zone" law. And do it right away.

Illinois Mining Men Visit Pittsburgh

During the week beginning May 6, a party of about 20 mining men from Franklin County, Illinois, visited the Pittsburgh district at the invitation of the United States Bureau of Mines, observing explosion tests in the Experimental Mine of the Bureau, and also studying the mining methods of the district. The party was under the leadership of Evan D. John, Director of the Department of Mines and Minerals of the State of Illinois, and consisted of a commission appointed by the Governor of Illinois to study Franklin County conditions, and of superintendents and foremen representing a number of coal companies, and of official representatives of the miners. This trip was made possible by the enthusiastic efforts of D. W. Buchanan, president of the Old Ben Coal Corporation. The program for the week was arranged by J. W. Paul, of the Bureau of Mines.

On Monday and Tuesday, May 6 and 7, demonstration explosion tests were held at the Experimental Mine, which is located near Bruceton, about 15 miles south of Pittsburgh. For these tests coal dust was prepared from a sample of coal from Franklin County, Illinois, which was furnished by the Old Ben Coal Corporation. The coal was crushed to the same size as the road dust samples which had previously been taken in the same mine from which the coal sample was obtained. Care was taken in the handling and preparation of this dust so that the natural moisture of the coal was practically all retained. On Monday, the coal dust was mixed with enough incombustible rock dust so that the explosion died out within the test zone. On Tuesday, the conditions of the test were changed so that a strong explosion was obtained. The explosion was stopped, however, by a special form of rock dust barrier (the Rice concentrated rock dust barrier, described in Technical Paper 84) developed under the bureau's auspices. Although pure pulverized Pittsburgh coal dust was loaded on the outby side of this barrier, a guncotton tuft nearly 6 ft. away remained unburned after the test, showing that the flame of the explosion was effectually stopped by the rock dust. On Wednesday, the party visited the Filbert mine of the H. C. Frick Coke Co., which is near Brownsville, Penn., and also the Continental No. 1 mine of the same company, near Uniontown. On Thursday, they went to the Keystone shaft mine of the Keystone Coal and Coke Co. On Friday, some of the men returned to the Experimental Mine to see a third explosion test, in which a small percentage of gas was used, while others visited the Montour No. 4 mine of the Pittsburgh Coal Company.

Most of the men returned to Illinois Friday night, feeling very well repaid for the trip. It is hoped that mining men from other districts will follow the example of these progressive Illinois men and make trips into fields other than their own in order to study modern methods which may have been developed in such other fields.

Conservation of Technical Engineers

Technical engineers of every branch of the profession who are taking part in the war activities of the Army and Navy are alarmed at the unfortunate waste of technical training caused by the drafting and enlisting of engineers for regular service with little or no regard for their technical attainments. These technically educated and experienced men are essential to the successful conduct of the war and cannot be replaced. There is continuing evidence that America is repeating in some measure England's mistake of sending technical men into the ranks when they should be carefully conserved for special duties in the fighting forces or on the technical staffs of the Army, the Navy and the essential war industries.

The Engineering Council, founded by the American Society of Civil Engineers, the American Institute of Mining Engineers and the American Institute of Electrical Engineers and other engineering societies, and representing some 50,000 engineers has addressed an appeal to the Secretaries of the Army and Navy that these men be placed in such places as will enable them to do work for which they are best fitted.

For this purpose it recommends that all engineers suited for technical service be enrolled and conserved for technical duties. Already from 10 to 15 per cent. of the members of the societies mentioned are in the uniformed service of the country, and it is safe to say that the majority of their remaining members are in the Government civilian service or are otherwise directly or indirectly engaged in the war.

Lubrication as an Aid in Stimulating Coal Production

By REGINALD TRAUTSCHOLD
New York City

SYNOPSIS — *The labor supply at coal mines is diminishing, and the car supply shows no signs of continuous adequacy. All possible mechanical aids to mining should be adopted, but first present equipment should be brought to capacity. In transportation equipment poor or inadequate lubrication means unnecessary and expensive frictional losses as well as an output not at a maximum. Oil as a pitcar lubricant has many shortcomings, most of which a semi-grease obviates.*

THE war, the weather, labor scarcity and curtailed transportation facilities all combined last winter in a drive upon the industrial activity of the country, a drive which failed in its objective only through the moderation in effectiveness of some of the forces mobilized. The cost of averting a serious coal famine was colossal. The most stringent measures had to be resorted to, much privation and no little suffering had to be endured. Yet in spite of the price paid, the drive was not entirely arrested, but simply retarded, with the prospect of a resumption next winter with added force, for the labor situation then will probably be even more acute than during the past cold season.

The war, the direct cause of the unprecedented demand for fuel, will tax our coal resources to the utmost. The weather may not be as severe as last year, it is true, but the car shortage cannot show any substantial improvement in view of the fact that no reserve car capacity can be built up while there is such a crying demand for every foot of carrier space that can be constructed, in spite of any degree of efficiency which may be realized by the Government in handling the available number of freight cars.

Mining Methods Must Be Bettered

The claim has been made by certain coal-mine interests that more coal could have been mined last winter with the labor then available had the railroads been able to transport it. Even if this be true, conditions will doubtless be much more critical next winter, for men and mules will then be much more scarce. It may be almost impossible to maintain even the coal output of last December and January with the present-day average efficiency in coal mining. Coal-mining efficiencies and methods must be bettered, if a catastrophe is to be averted.

Every mechanical aid for the miner must be adopted. Mining machines must be more extensively used to cut the coal, greater care must be taken in laying out trackage and proper attention to rolling stock will be mandatory. All this, and more, must be done with the least possible interference with the present rate of coal production. No curtailment of output can be tolerated, nothing but increased production countenanced.

The very first requirement, then, is to bring present equipment up to the highest possible standard of efficiency and maintain such improvement. This will materially lighten the labor of the underground workers, facilitate the handling of the coal on the tipple, etc. It is a necessity, if output is to be stimulated with a decreased number of men. With a limited working force, fatigue will be an unusually vital factor in the efficiency with which the underground workers and the mine mule can labor.

The work of the miner can be lightened and output maintained (in spite of fewer available skilled workers) by supplying him with every mechanical aid, by the more general use of mining machines, and the loading of mine cars with mechanical loaders; simultaneously the transportation of the mined material, between the face and the tipple or shaft bottom, can be made much easier, if the mine-car journals are kept properly lubricated.

Efficient Lubrication Means Economy

The lubrication of mine cars offers one of the most profitable of fields for betterment in mine operation. Any improvement attained therein represents a net monetary saving without a cent of initial investment. At any time, proper lubrication of mine cars pays a handsome profit, but in periods of stress the gain is increased several fold. Thousands of mine-car journals are not properly lubricated today, and, compared with those which are, they entail not only a serious waste in power, whether this be man, mule or mechanical, but a lubrication cost of from 10 to 20 per cent. more than in the case of properly lubricated cars—frequently, even a larger percentage. In this waste, for it is nothing else, no account is taken of increased deterioration, breakage and replacement charges for poorly lubricated mine cars. The figures given cover only the waste resulting from decreased lubrication efficiency.

The variety of running gear on mine cars naturally has a decided effect upon the ease with which the cars can be handled, and consideration should be given the question of substituting improved bearings for those of less efficient type. But the first step taken should be to secure the most efficient lubricant for the existing journals and see that such lubricant is properly employed.

The lubrication problem in a coal mine is a serious one, for the service to which the mine cars are put is severe. More or less dust and dirt is present in the air; the bearings are subjected to marked variations in load, on account of the unavoidable heaving of the cars as they pass over inequalities in the roadbed; the tracks are apt to become slippery through dripping lubricant, thus reducing the effective tractive power of

the haulage motor. Also, in certain sections of the mine, at least, illumination is insufficient to permit satisfactory inspection of bearings.

The requirements for an efficient car lubricant are: "Body," or viscosity, sufficient to prevent contact of surfaces; freedom from corrosive acids; as much fluidity as is consistent with body; effectiveness in reducing friction; high flash and burning points; freedom from substances likely to cause gumming or oxidation.

A lubricant to possess these six essential properties can only be produced from non-gumming, paraffin base, petroleum oils. It should have the "tenacity" of grease and reasonable durability if it is also to possess the necessary quality of being economical in use. In addition, it should be nonvolatile and not liable to change under the variations in temperatures encountered in mine service. Such temperatures are fairly constant throughout the year within the mines, but out in the open are subject to variations from zero in winter to around the hundred mark in summer.

The requirements of an efficient mine-car lubricant have thus been emphasized before considering the shortcomings of "black strap," or "black oil," the usual lubricant for mine-car journals since almost the days of the first coal mine, in order to show the lubrication problem confronting every coal-mine operator.

Without going into a scientific analysis of black oil, the composition of which is found to vary considerably in different localities, some of its admittedly common failings will clearly demonstrate that it cannot successfully discharge the functions of an efficient mine-car lubricant. In the first place, its body is readily affected by heat, as are also its lubricating qualities. At some definite temperature it is doubtless of the desirable density, but when subjected to heat, frictional or otherwise, it becomes so fluid that from 50 to 90 per cent. escapes from the bearings. These leakage figures have been repeatedly confirmed by carefully conducted tests under actual working conditions. Consequently, from two to ten times as much black strap has to be employed as is effective in reducing journal friction.

Serious as is the monetary loss from this direct waste of lubricant—cheap, though the oil may be—the after results are nearly sure to be even more expensive. The dripping oil is liable to fall on the track, resulting in a decreased grip of driving wheels on the greased rails and unprofitably taxing the haulage locomotive. The footing for haulage animals is in some cases made insecure and the galleries and passages become more or less saturated with an inflammable oil. The flash and fire points of black strap are relatively low, so that the already high fire risk of a coal mine is increased—particularly should there be any wooden trestles for the cars to pass over such as overcasts, and the like. Furthermore, an oil that so readily increases its fluidity in ordinary service as black oil, will as readily gum.

A lubricant of insufficient body—whether its excessive fluidity is characteristic at ordinary temperatures or developed under slight heat—cannot prevent contact of bearing surfaces under load, so that the coefficient of journal friction remains high. In mine-car service this is particularly disastrous, for the heaving of the car as it travels over any inequality on the track first squeezes the thin lubricant from the bearings and then sucks it back again charged with whatever dust and grit has been gathered from the air. The abrasive material thus carried into the bearings proceeds to "gouge" the wheel bores and axles.

A summation of even the few disadvantages attendant upon the use of black strap as a mine-car lubricant here enumerated would total to a considerable amount if valued in dollars and cents.

The essential properties of an efficient mine-car lubricant—requirements which will not only stimulate production but are demanded by economic considerations for minimizing coal-mine risks—are not all to be found in any one natural oil or grease. For a lubricant to possess the six functional properties combined so as to discharge effectively the exacting duties demanded in mine-car operation, it must be a blend of mineral oils scientifically, accurately and intimately compounded.

No coal mine has the facilities or the experts with the necessary experience to produce such a lubricant, even if the various ingredients were available. This is a task for the highest skilled specialist, with the facilities afforded only at the works of an oil refiner actively engaged in the production of lubricants.

The Swan & Finch Co., of New York, produces the mine-car lubricants marketed under the trade name Slo-Flo. These lubricants are the result of much experience and testing in the light of an intimate knowledge of the requirements to be met. The use of these semi-greases has been so satisfactory that a number of mine-car manufacturers now recommend the particular grade of this lubricant best suited to their particular running-gear construction.

Successful Mine-Car Lubrication

Such lubricants must obviously be procurable in more than one grade, for the lubricant best suited for one type of bearing is not necessarily the most desirable for one of a different class of construction, even though the service for the coal cars which the bearings are to serve may be identical. For instance, the lubrication of a plain cast-iron bearing does not present the same problem as does that of one of hollow flexible roller construction, such as the Hyatt. A comprehensive study has been made of mine car lubrication and lubricant suitable for each specific construction developed. Though this may multiply the number of lubricants for the coal mine to stock, it has the decided advantage of furnishing the mine owner with the concrete results of years of experimenting and testing on the part of lubrication experts.

Furthermore, the quality of these lubricants is invariably backed by comprehensive guarantees for satisfactory results, so that the mine owner who will use the product of a lubricant producer of standing, assumes no risk. No reputable oil refiner dares to make claims for his products, today, which cannot be substantiated in competitive tests. The efficient compounding of lubricants has become a science, the importance of which is daily becoming more generally recognized, and sales are now more often closed on the strength of economic and efficient results than, as frequently in the past, on the basis of initial cost.

Proper lubrication of mine-car journals lessens the arduous task of handling the cars and permits the transportation of maximum loads. It is an invaluable aid in stimulating coal production.

Book Reviews

Shows Where Coal of Given Quality Is Obtainable

THE COAL CATALOG COMBINED WITH THE COAL FIELD DIRECTORY. Pp. 671; 9 x 12⅝ in.; 96 ill. Keystone Consolidated Publishing Co., Inc., 302 Penn Ave., Pittsburgh, Penn.; price $25, Cloth boards.

The "Coal Catalog" is the first attempt we have seen to supply the coal purchaser with such facts regarding the coal industry as he has long needed. Judging by the many letters which come to *Coal Age* regarding the places where coal can be purchased of a certain specific kind, it is evident that a book of the nature of the "Coal Catalog" is in great demand, and it is therefore not at all surprising that the number of copies disposed of is already large, especially in view of the disorganization in distribution resulting from the coal shortage and the zoning regulations. The reader of this notice will probably judge from the title that the book is a catalog of mining machinery with a minimum of directory. He will be surprised, therefore, to learn that the book has no advertisements whatever and makes no mention of mining equipment except in listing the outfits owned by the various mines. Even in this case the names of the concerns by which the equipment was manufactured are not given.

The volume opens with twenty pages on the geology of coal, followed by four pages on geological and mining terms. These are doubtless included as a concession to completeness. The real interest to the coal buyer starts with page 33, where a description of the coal areas of the United States is given followed by a map of the United States with all the fields plainly delineated.

Listed by Mineralization, Use and Structure

Then follows a classification of coal, and this the coal purchaser will find most interesting. The matter is generally none too well understood, and Mr. Zern has done well to quote from Marius R. Campbell's "The Coal Fields of the United States" for the first classification, which is "according to rank," that is, "according to the degree of mineralization," which, by the way, would probably be a better way to describe the method of division. The second classification, "according to use," is probably the most interesting of all classifications. The purchaser is apprised in this section regarding the type of coal that will suit his particular purpose whether he needs it for beehive coking, bunkering, byproduct coking, cement burning, domestic use, export, the manufacture of illuminating gas, use on locomotives, metallurgical use, use as powdered fuel, the manufacture of producer gas, the raising of steam, smithing, tile and pottery burning, or the making of water gas.

The third division is according to physical structure. In this division block coals, splint coals and smokeless coals are described. It may be noted that the author does not say what the structure of smokeless coals is, and it may be doubted whether a smokeless coal must necessarily have any given structure. The smokeless coals of Pennsylvania are different from those of Maryland.

Three pages on preparation of coal and seven on coal storage follow those on classification, and three pages are given to coal analysis, in which the bearing of the presence of moisture, volatile matter, fixed carbon, ash, sulphur and phosphorus in coal are discussed.

A tabulation is made in Part II of all the types of coal and the fields and seams of their occurrence, and in these tables the places in the book in which such types are described are correlated. Thus the reader can readily find where the coal in which he is interested is described, where its analyses are given, where the operators of the seam or field are listed and where the directory of the mines operating in the seam or in the field is to be found, and this for the whole United States.

The coals are divided up not only according to mineralogical rank but also according to their use. Thus if you desire anthracite coal you will find it is produced in the Gunnison County field of Colorado, and the details just noted can be found on certain specified pages. If a search is being made for a coal suited to brick and tile burning, the reader will find that the Hartshorne lower seam in Oklahoma is adapted to that purpose, and that references to the seam and its characteristics can be found in four pages specified.

Pennsylvania Has 57 Per Cent. of All Wasteful Ovens

A long list of coke ovens follows. Pennsylvania is credited with 48,708 beehive and rectangular ovens, West Virginia is said to have 16,511 such ovens and Alabama has 6111. It is interesting to note that Illinois has only 104 such ovens, Ohio 178 and Oklahoma 200. A list of byproduct ovens is given with the consuming capacity of the ovens, and the estimated coke production.

In Part III we come to the separate states, Alabama leading. It is fair to take it as a sample, seeing that it is a state where the editor of the "Coal Catalog" has, if we mistake not, never been domiciled. Columnar sections of the coal measures are followed by a map of the state with the basins clearly outlined. Each basin is described at length in the sections that follow. Almost a page of typical analyses are also given. The mines are then listed by basins and seams, and some account of the customary modes of preparation are given. Then follows the regular directory material with which our readers are already familiar.

About each mine new information has been added regarding the character of the product—whether it be steam, coking or smithing coal, for instance; the trade name—Blue Creek, for example; the mining district—Warrior, let us say; the size shipped—run of mine, slack, pea, nut, egg and what not; the preparation equipment—shaking and revolving screens, washery or some like description. Thus the reader knows that the particular type of coal for which he is looking can or cannot be provided for by the firm listed.

How the Coal Fields Are Delimited

In some states the fields are so naturally distinct that it has been possible to map them. In others the device is to use a circle round the natural center of the field described. Thus in Arkansas circles mark out the Bates-Coaldale, the Greenwood-Huntingdon, the Bonanza-Jenny Lind, the Denning-Coal Hill, the Spadra and the Paris fields. But in Colorado there is a different plan, the fields being clearly separated, though here the coals of any one field are not of uniform character. In Maryland, of course, it is quite easy to name and chart the fields and consequently it has been done.

The anthracite region of Pennsylvania is admirably treated in this volume. A number of cross-sections are given, the character of the coal in each region is noted and a valuable map of the different districts has been added. No attention is paid to the seams mined. Most concerns mine and mix the coals from many seams, and the many different names used to designate a single seam and the many splits of the same seam make identification almost impossible.

The editor, E. N. Zern, has done the best he could with the Pennsylvania bituminous region. Some day something better will be done, but at present the trade names being used are quite vague and misleading. Owing to the

difficulty of securing a more perfect nomenclature these trade names have been used by the author and no definite limits to the areas designated have been drawn.

For instance, DuBois is allowed by the editor to choose its own district. It can make its selection between the Reynoldsville, the Shawmut and the Clearfield districts. Though DuBois is in Clearfield County, the coal more closely resembles that from the Reynoldsville field adjacent. Probably it will ultimately be classified in that field. The Clearfield coal might be better called Moshannon or First Basin coal. But in that event something will have to be done for the naming of the two intermediate basins.

Mr. Zern has merely attempted the possible. Had he boldly broken with trade names, the trade would doubtless have only been confused and he would have involved himself in endless discussion. Still, some day the work must be done, and surely the tidewater pooling arrangements might be held to serve as a guide wherever they are in effect. It would do no harm in future editions to give the groupings in which these pools are divided.

There is in this book much of great value to every one who produces, trades in or uses coal. It is a wonderful compilation, made by one who is probably more capable of performing the work than any other man except some of the officials of the United States Geological Survey. The work has been done conscientiously. It is a model production in every way and one the industry may be proud of. The 671 pages are full of material that it took much labor to assemble and much scholarship to compile. We have no hesitation in giving it unqualified approval.

Must Make Drastic Coal Saving

After a detailed survey of the fuel situation, Dr. Garfield, on Monday, June 10, called the newspaper men into his office and told them that the matter of fuel supply for the coming year "is one of the most difficult and threatening problems the war has presented." Requirements aggregate 80,000,000 tons more than was produced last year. It was pointed out, however, that unexpected additions to estimated fuel requirements are taking place all the time, and it was admitted that 100,000,000 tons is an estimate which provides only a nominal margin of safety.

It is estimated that the 360 non-war industries will require about 100,000,000 tons of coal. It is believed that production of coal this year will exceed by 50,000,000 tons that of last year. To prevent serious curtailment of industry, fully 60,000,000 tons of coal must be saved by various means of conservation. At the conference, the correspondents were furnished with a written statement of the situation. This extract from that statement shows the seriousness with which Fuel Administration officials regard the outlook:

A saving of sixty million tons of coal is the one possible avenue of escape from national disaster. Necessities of war must be supplied. The coal deficit must inevitably come out of the necessary fuel for non-war industries. These industries employ millions of our population and furnish the backbone of our national wealth. Factories will shut down and men be out of work in proportion to the coal deficit. Every ton of coal saved will keep fifty workmen from idleness and permit an additional creation of several hundred dollars worth of national wealth. The Fuel Administration has frankly given to the public statistics of an alarming fuel situation. It desires to state just as frankly and with all the emphasis possible that it is in the power of the American people through fuel economy to save the country from the effects of the fuel famine.

Since fuel and steel are the two factors which are limiting the non-war industries, Dr. Garfield explained that the reduction of supplies in these two commodities will be equal. Steel plants might find it possible, for instance, to furnish 50 per cent. of a plant's requirement of some specific kind of steel, but the Fuel Administration, in its allotment, might find that that plant is entitled to only 25 per cent. of its normal fuel supply. In such a case, only 25 per cent. of steel would be allotted. Arrangements have been made whereby the maximum reduction is to apply both to coal and steel.

Dr. Garfield told of his efforts to find the country's non-essential industries. He admitted that he has been unable to find any such industry. The Fuel Administration, however, has compiled a list of the non-war industries from which it will be necessary to take such fuel as may be required to meet the demands of the war industries. P. B. Noyes, the head of the conservation division of the Fuel Administration, told of efforts being made to build up war industries in communities supported largely by non-war industries, so that there would be no unemployment or disruption of established conditions of the community.

The velocity of combustion of hydrocarbons is faster than velocity of decomposition; therefore, combustion will take precedence over decomposition. For this reason air supplied over the fuel bed should be admitted as near to the surface of the bed as possible and mixed with the hydrocarbons, so that they will be burned before they are decomposed by heat and form smoke, which is difficult to burn in the rarefied oxygen of the furnace.—*Bureau of Mines Bulletin No. 135.*

Ideas and Suggestions

LARGE numbers of men have left the mines for employment in more lucrative industries. Thousands have been called to the colors, thousands more will be called in the future. Meanwhile the country is confronted with the likelihood of a fuel shortage that promises to curtail seriously the output of supplies essential to the welfare of our army in France and to interfere grievously with our war plans. In bituminous coal alone the mines of the United States must furnish over 630,000,000 net tons to satisfy the voracious appetite of our war machine and to keep the country warm the coming winter. It readily can be appreciated, therefore, that all ideas or plans which enable a mine to function to maximum capacity should be the common property of the entire coal-mining industry. If you know of a device that saves in time, labor or money; of a makeshift that was employed to prevent a shutdown while waiting for parts from the factory; of a system of mining that resulted in greater coal production; of a plan that filled the men with patriotic enthusiasm so that they labored more steadily and more efficiently—in short, if you have a suggestion that will help to win the war by the mining of more coal, it is your duty to write it up for publication in *Coal Age* for the benefit of its many readers. Sketches, diagrams or photographs should accompany the text in all instances where these are necessary to convey the message clearly. Aside from enabling you to do your part is the fact that if your contribution is accepted it will be paid for liberally.

To Increase Coal Production

It is necessary to add 1,000,000 tons to the weekly coal production if a serious shortage is to be avoided this winter. Having established the certainty of this fact, the Fuel Administrator has placed the difficult task of securing this production in the hands of James B. Neale. Mr. Neale has been placed at the head of a new section of the Fuel Administration, which is to be known as the Production Bureau.

While the weekly average production is now running over eleven and one-half million tons a week, it is now clearly apparent that a weekly average of a million tons more must be maintained from now until the end of next winter if the greatly increased demand for coal is met in its entirety.

The Shipping Board estimates that 30 per cent. more coal will be required for bunkering purposes than in 1917. Expansion of war industries will call for 18 per cent. more coal in 1918 than in 1917. Public utilities will call for 15 per cent. more coal. Thirteen per cent. more coal will go to domestic consumers, while the railroads must have at least 7 per cent. more coal than they had last year. The details of the Fuel Administration's estimate of the requirements are shown by the following:

	1917 Amount	1918–19 Amount	Per Cent. Increase 1918–19 Over 1917
Industrial	204,907,000	242,024,000	18
Domestic	66,915,000	75,678,000	13
Gas and electric utilities	33,038,000	37,941,000	15
Railroads	155,000,000	166,000,000	7
Exports	24,000,000	24,000,000	0
Beehive coke	52,450,000	52,450,000	0
Bunker—Foreign	7,700,000	10,000,000	30
Bunker — Domestic, including Great Lakes	5,000,000	5,000,000	0
Used at coal mines for steam and heat	11,000,000	12,500,000	14
Total	560,010,000	625,594,000	12
Used from storage	4,375,000	.....	....
Exports	907,000	.....	....
Estimated production	554,728,000	.....	....
Substitution of coal for oil, mainly in west	.....	2,000,000	....
To increase stocks of industrial plants and public utilities outside of New England by ten days' supply	.....	7,000,000	....
Total requirements for 1918 without allowance for estimated conservation	.....	634,594,000	....
Production 1917	554,728,000	.....	....
Production 1918 required for needs	634,594,000	.....	....
Increase required	79,866,000	.....	....
Percentage	.....	.....	14.4

The Fuel Administration has moved into its new building at New York Ave. and 20th St., Washington, D. C. The entire Fuel Administration now is housed under one roof.

Weekly Production Statistics

Despite a generous car supply coal miners at many properties insisted on observing Memorial Day. This resulted in a slump of more than a million tons in production during the week ended June 1. Total bituminous production during that week was 10,774,000 tons. Anthracite forwardings, largely for the same reason, decreased 22 per cent. Total shipments were 31,762 cars.

Beehive coke production fell off 7.7 per cent. during the week ended June 1. Total production was 612,000 tons. Byproduct coke production for the week ended June 1 was 479,776 tons, a decrease of 4626 tons as compared with the week preceding.

The figures used above are based on estimates made by C. E. Lesher, the geologist in charge of coal statistics for the United States Geological Survey.

M vement of West-Bound Coal Further Restricted

Further restrictions are to be placed on west-bound movement of eastern coal. An order effective June 20 has been issued prohibiting west-bound movement from all mines located on the Chesapeake & Ohio in the Kanawha district from St. Albans, W. Va., eastward. The movement to Indiana of any high-volatile coal from the Kanawha and Kenova-Thacker districts of West Virginia and the Big Sandy district of Kentucky will be prohibited.

Warns Against Unnecessary Use of Electricity

United States Fuel Administrator H. A. Garfield has warned the public against prodigal and unnecessary use of electricity for outdoor advertising purposes and other display illumination.

The Fuel Administrator said this waste must be stopped. Unless official reports show that display illuminations are kept within reasonable bounds, and are limited to the hours of darkness, the suspension of the so-called "lightless night" order will be revoked and even more stringent restrictions will be ordered against all forms of outdoor lighting and display illumination. The consumption figures recently compiled reveal the necessity of the utmost economy in fuel during the summer as well as the winter, and require the early enforcement of the strictest economy of all fuel-generated electricity.

Coal Exports During April, 1918

Exports of bituminous coal, during April, show an ıcrease over the corresponding month of last year. In .pril of 1918 exports were 1,554,579 tons. This com- ıres with 1,389,899 tons in April of 1917. Anthracite ‹ports show a decrease. In April of this year 340,783 ›ns were exported, whereas in April of 1917 exports ere 586,367 tons.

Increased exports were shown to the following coun- ·ies:

	April 1917 Tons	April 1918 Tons
Canada	912,653	1,127,705
Cuba	112,802	212,355
Panama	48,094	70,870
Uruguay	4,329	6,107

Decreased exports were shown to the following coun- ·ies:

	April 1917 Tons	April 1918 Tons
Italy	72,771	2,016
Mexico	16,161	12,675
West Indies	35,941	28,063
Argentina	31,612	9,869
Brazil	51,807	25,097
Other countries	103,729	59,822

Coke exports in April of 1918 were 141,003 tons. In ıe corresponding month of last year they were 79,759 ›ns.

Reduction in Carload Prices from Lake Docks

Reductions have been ordered by the Fuel Adminis- ·ator in prices charged for bituminous coal shipped in ırload lots from Lake docks. The new prices are: oal from Youghiogheny, Fairmont, Greensburg, West- ıoreland, No. 8 seam Ohio, Hocking and Pomeroy elds, lump $5.80; run-of-pile, $5.55; screenings, $5.30; :arlan, Thacker, Kenova, Kanawha fields, lump, $6.30; ın-of-pile, $6.05; screenings, $5.80; Pocahontas, New iver and Tug River fields, lump, $6.30; run-of-pile, 6.05; screenings, $6.05.

The order provides that any increase in freight rate ıay be added to the prices. Licensed jobbers are al- ›wed a margin of 20c. a ton for handling coal from ıe docks

L. A. Snead Resigns

L. A. Snead, who has been associated with the Fuel .dministration since its foundation, has resigned. ·or some time, Mr. Snead was in direct charge of the nportant work of apportionment and distribution for ıe Fuel Administration. He served the Fuel Adminis- ·ation as a volunteer.

Freight Rate Order to Be Modified

Important modifications are to be made in general rder No. 28 issued by the Railroad Administration. : was this order which made the recent drastic increase ı freight rates. Paragraph C of section 1 of that order eads: "All intrastate class rates shall be cancelled ·here there are interstate class rates published be- ween the same points and the interstate rates, as in- reased, shall apply." This paragraph, it is under- tood, is to be modified so as to permit the application f intrastate rates to which an increase of 25 per cent. has been added. Regional directors have been instructed by the Railroad Administration to preserve all existing parities and differentials affecting imports and exports. The regulation providing a minimum charge of $15 for carload shipments is likely to be stricken out.

Rates to "Short-Haul" Territory Found Unjust

The coal rate adjustment from mines in Pennsylvania to "short-haul territory" has been found by the Interstate Commerce Commission to be unduly preferential to Alicia, Bridgeport, Pike and Braznell, Penn. It was also shown to be prejudicial to Diamond. The Commission holds that the rates from Diamond should not be higher than those contemporaneously maintained from mines in the vicinity of other places mentioned. What is known as the short-haul territory is the region including Buffalo, Rochester and Pittsburgh on the east and is bounded on the west by a line running through Lorain, Ohio, and Orville.

Furloughs for Really Indispensable Men

In response to appeals from all over the country the War Department has decided upon a policy that will permit conscripted men who are highly skilled in necessary industries to return to their former employments. The system of furlough will be automatic, and will not in the future, as in the past, leave to the discretion of company and other subordinate commanders the question whether such furloughs should be granted.

An application blank has been prepared by the War Department known as the "Application for return of enlisted man in highly skilled class of labor to necessary industry." The application when filled must state the direct Government contracts held by the applicant or the names of the persons having such Government contract with whom contracts have been made by the applicant. The applicant must add a statement that the status of his business as a "necessary" industry has been filed with the district board. The application must be duly sworn and a Government inspector conversant with the facts must sign the papers.

The signed application then goes to the Adjutant-General's office with a request from the interested Government department stating that it desires that the man be granted an indefinite furlough without pay. The employer makes a promise that after the need for the man's service has passed he will be returned to the Army and the Government notified.

While on furlough he will not be allowed to wear the uniform. Every month the company employing such men must furnish the Government a report that such men are still in employment and state the class of work they are engaged in. In case such men leave their employment the employer must immediately notify the Government.

John W. Poe, of Roswell, N. M., has been appointed fuel administrator for his state. He succeeds W. C. McDonald, recently deceased. Mr. Poe is president of the First National Bank of Roswell and is a member of the state tax commission.

THE LABOR SITUATION

General Labor Review

While the patriotic purposes of the bulk of the miners and other mine workers have made strikes infrequent and short, other causes for tonnages below capacity still remain. There is an important minimum of mine workers everywhere who are not patriotic enough to work day after day. They satisfy themselves by working just enough to make a living, and when that is achieved, or appears likely to be achieved, they absent themselves from the mines or work short hours.

This absenteeism is quite a serious matter and the method to prevent it taken by the Lehigh Valley Coal Co., illustrated and described elsewhere in this issue, is certainly worth imitating. There are enough patriotic men in every colliery to put this plan in circulation and surely it ought to be done. It is a sign that a man has not bought as many Liberty Bonds as he can carry if he is "lazing" away his time when the mine is working.

Unions Should Squelch Mine Absenteeism

In places where the union is strong, the unions themselves should take up this matter. One hundred per cent. working and 100 per cent. production by those who are working is what the country needs and has a right to expect so long as the war lasts. Steady work made an aim in itself, duly recorded and posted at the mine, will correct many of the evils that now need correction. Many of the men who refuse to work more than half time can prove to the satisfaction of everybody that at the existing rate of pay they cannot buy bonds and support their families. Once they work with 100 per cent. regularity and with 100 per cent. of energy they will find they are capable of helping their country in much larger measure.

The United States Fuel Administration is very wisely endeavoring to stir up that enthusiasm which alone can meet the difficulties and sweep away in its powerful current, strikes, absenteeism, holiday making, inefficiency of day men and underproduction of miners. Coal production is one of the most worthy occupations of all those pursued by civilians behind the fighting lines, and, duly presented, this fact will not fail to do its work.

The administration's speakers at a recent meeting at Jamison No. 2, near Greensburg, Penn., were Sergeant Major J. Armstrong Young, of Virginia, a member of the Canadian Heavy Artillery; Alfred Korzybski, of Warsaw, who was a staff officer in the Second Russian Army under the Grand Duke Nicholas of Russia, and Lieutenant Klymnecky, who also served with the Russian Army. The first of these, the Virginian, served in France for 21 months. He was wounded twice and gassed at Vimy Ridge.

Funeral Layoffs Still Slow Down Business

An unfortunate idleness at the Stanton Colliery of the Lehigh & Wilkes-Barre Coal Co., June 8, illustrates the fact that some men are not any too anxious to work. This company announced some years ago that it would pay $100 to the family of any mine worker killed if the men at the colliery would work on the day of the funeral. It had been the custom to lay the mine idle on the day of the ceremony though only a few attended the funeral. Of course, the pall bearers and the kin of the deceased were allowed to keep the day in the appropriate manner, but still attendance was in the main restricted to these men.

However, when the legislature recognized the fact that it was well that every employer should indemnify the families of those killed in his service by a larger indemnity than $100, the Lehigh & Wilkes-Barre Coal Co. paid the larger amount and that only. The men do not recognize their obligation now to keep at work and think that by celebrating the funeral by an abstention from labor and by shutting down the mines they can force the coal company to pay $100 extra to the families of mine workers killed at duty.

As against the action of these Lehigh & Wilkes-Barre Coal Co. men may be set that of the men of the Lehigh Valley Coal Co. By the way the Lehigh Valley men are always loyal to the nation and leaders in loyalty, wherever you find them. Strange to say, the men who show the characteristic most markedly in the week's news are the men at the Broadwell Colliery, at Moosic. The public never speaks without displeasure of Moosic and its neighboring towns in the south. It is the home of the Industrial Workers of the World. Its neighbors are Avoca, Dupont and Old Forge and other towns which are peopled by strange men of Bolshevic tendencies, men with eruptive follies of every kind. But the Broadwell Colliery is the first oasis beyond a land of trouble. The broad-gauged policy of the Lehigh Valley Coal Co. may have something to do with this.

Want to Work Sunday for American Red Cross

This colliery has worked every day except Sundays, Christmas and New Year. It has also asked to be allowed to work some one Sunday, celebrating it as a "Red Cross Day," the proceeds of its earnings to be turned over to the American Red Cross. The men have unitedly gone on record against any and all miners who feel inclined to stop work on any pretense, and they indignantly repudiate any "slacker" charges made against the mine workers in the anthracite region. And now they have taken the further step of opposing the drafting of men from the anthracite mines until the present scarcity of men comes to an end, and that end unfortunately is nowhere in sight.

They are absolutely right in this stand. If it is justifiable for the United States Government to take 6000 lumber men out of the New National Army to cut spruce for airplanes, as has been done—and justifiable indeed it is—surely it is right to keep enough men in the anthracite industry to supply at least the minimum of coal needed for the conduct of our national life and war industry. A maximum output cannot be secured if the 145,000 men now trying to get out the coal needed is to be further reduced by the draft. Already 32,000 men have been taken from the anthracite mines since the war began.

Supreme Importance of Anthracite Production

It is essential that the coal production be maintained in that field of coal which is nearest to the great national gateways and the leading national industries. The East has altogether too many war factories. The railroads cannot supply them with the needed transportation and consequently the extension of these factories will not be permitted. Their operation, however, is needed at full strength, and that operation will be found impossible if the anthracite field near by them has a reduced output and as a result the domestic coal used by the industrial workers and the steam coal used by the factories has in larger measure to be brought even longer distances than heretofore over the overburdened national roadways.

The miners in general have not, so far, sought exemption because it appeared on its face unpatriotic and cowardly, and there is nothing that the miner more bitterly resents than an aspersion of his patriotism and his bravery. The coal-company officials, fully realizing the national needs, were willing to sign exemption papers, but the mine workers did not present them for signature to their employing companies even when the former were prepared to ask, and did ask, exemption. They frequently had the request for exemption signed by a "buddy" or a neighbor.

And, furthermore, the officials of the draft boards, realizing that it would be impossible to obtain a quota in the anthracite region without taking mine workers, were but little disposed to exempt anyone or place anyone in the deferred classification, no official recommendation to that effect being in existence to justify such an action. Captain W. A. May, president of the Pennsylvania Coal Co., states that his company lost 265 men to the draft last month and that the situation is quite serious. The shortage of men in the mining industry of Lackawanna County is 7932, out of the 35,744 men employed in the coal industry of that county. It is easy to see how the work is hampered.

Action though deferred is coming at last. Acting under the instructions given at a conference at the state draft headquarters which occurred June 6, most of the coal companies have filed exemption claims for those men who are scheduled to leave either June 24 or in future drafts. The local draft boards have been informed that they have authority to commend deferred classification for miners and to reopen cases of such workers on the same basis as railroad men and farmers. The conference was attended by Major W. G. Murdock, chief draft officer; Seward E. Button, chief of the Pennsylvania State Department of Mines; George F. Buss, sheriff of Luzerne County; James M. Donnelly, former mayor of Pittston; George P. Gallagher, district superintendent of the Lehigh Valley Coal Co., at Pittston, and H. R. Johnson, superintendent, Lehigh Valley Railroad Co.

The strike at Honey Brook No. 5, of the Lehigh and Wilkes-Barre Coal Co., mentioned in the issue of last week, ended June 6, the 12 men who would not pay their union dues being discharged. Whether they were really Industrial Workers of the World or not has been a matter for argument. But this much is certain, the I. W. W. did try to establish itself at McAdoo and Tresckow, nearby towns to Audenried, where the Honey Brook operation is located. They could not obtain meeting quarters and they had to meet in the woods near McAdoo. This marks the failure of the first and, let us hope, the last attempt to build up the "I Won't Works" in the Lehigh field.

Ohio Men Want No Foreigners in Union

The miners in parts of Ohio are determined to make the mines 100 per cent. American. The largest local union in Ohio, that comprising the miners at Webb mine, Bellaire, has resolved that every miner have at least his first naturalization paper or forfeit membership in the union.

Its action will probably not lay off any men, for few foreigners have arrived in America since the war started and so all have had a chance to declare their intention. But, as has been stated, the spirit of Americanism is not conferred by naturalization, and lacking it the naturalized foreigner is like the unconverted reprobate at the mourners' bench. If he is disloyal he is likely to create a scandal sooner or later. It is not well to try to convert anyone to anything by offering the "loaves and fishes" of a job.

Unionization is progressing in the Fairmont region of West Virginia under the sanctioning provisions of the recent contract. The mine workers of the large "New England" mine of the Consolidation Coal Co., at Watson, W. Va., were recently organized by the United Mine Workers, between 200 and 300 joining the union. The organizers were C. H. Bradley, an international representative, and C. F. Keeney, the president of District No. 17, with James Diama, whose work it was to round up the Italians.

The new plan is not working as smoothly as hoped. It had always been feared by those who opposed the union that the Colorado system might prove to be a plan under which the union would be recognized, instead of one in which the union is allowed to exist, but is not permitted to make a contract. In West Virginia it appears that the mine workers of some places chose the same men for union leaders as they had selected for their representatives under the contract. The company is therefore dealing with an organized opposition backed by the funds of mine workers throughout the country. That fact was to be expected.

The Consolidation Coal Co. has graciously submitted to the inevitable. Frank Keeney, the president of District No. 17, declares that he has 3500 members in the vicinity of Fairmont and that at two mines the men would not organize although urged to belong to the union by the superintendent. Mr. Keeney says that the operators have been extremely courteous to himself and to "Mother Jones."

After all, the union starts its existence with friendly feelings where bitterness might well have been expected. The Consolidation Coal Co. wisely realizes that the union should either be a friend or an enemy. The company has elected to be friendly to the union, and it is quite probable that it will find the union will reciprocate. Most companies sign up with the union and then refuse to bury the hatchet. They do all they can to maintain the hostility. The better plan is to try to get along with your partner if you know or believe that he is to be your partner for life.

Operators in the Illinois fields are complaining of the increasing difficulty of getting men to work in the mines and in keeping them at work when they get them. The trouble is not so much desertion of the industry for other lines of work, although there is some of that too. Principally it is the disinclination of the miners to work regularly when they can make a living by working only part of the time.

Patriotic Workers Round Up Rest

Anti-slacker committees made up of anthracite miners bent on singling out their fellows who are taking days off without legitimate excuse, are at work at the mines of the Lehigh Valley Coal Co. They are an answer to a patriotic

TO KEEP TRACK OF THE MINE SLACKER

appeal that the officials of the company have made to the employees urging them to eliminate unnecessary absence from work during the present grave labor shortage in the anthracite fields.

"The results are already better than we had dreamed," said President E. E. Loomis. "Following the 'Four Minute Man' idea, we are having good speakers talk to our people, pointing out existing conditions and appealing to them, from patriotic motives, to coöperate with us to their fullest extent that a maximum coal output may be attained. At every colliery we have erected giant thermometers which show the tonnage produced by that colliery each day as compared with its best record, and alongside are the names of absentees with an estimate of what the tonnage would have been if all had been on the job. The effect is electrical. Practically every man has been put on his mettle, and there is a general demand by the men to be put on these 'slacker' committees."

EDITORIALS

HEAVY and unequal taxation has been so oppressive in Turkey that it has always served to prevent that country's development. Such taxation is proposed for the United States by persons of undoubted patriotism. But no matter how patriotic they may be, the reasons for objecting to extremely high taxes on essential industries are by no means unpatriotic. Without dogmatically assuming any unusual certainty on these matters, it may be well to state the arguments of those who are opposed to extremely large taxes. Washington may well have facts permitting of a different point of view to that here taken. So far it has not presented them.

If every man had his money and time invested in a single enterprise, and the Government took 90 per cent. of his profit, he would be left with 10 per cent. and might be well content. He would say it was the war, and admit the justice of the tax. But men are not engaged in only one line of endeavor. Most wealthy men have a large number of industrial investments. Some are losing ventures and some are prosperous. The investor balances one against the other and in normal times shows a satisfactory balance.

* * *

NOW heavy taxation upsets that balance. The prosperous businesses make a tenth, let us say, of what they did before the taxes were raised and considerably less than before the war because of price regulation, while losing ventures—and there are not a few of these—are in more desperate straits than ever. Clearly, then, the investor does not merely give 90 per cent. of his income to the Government. The Government gets 90 per cent. of the earnings of his successful investments, while the investor gets his 10 per cent. and loses steadily in the conduct of all his other business.

The investor is on the way to penury. It is clear that he will run no risks whatever in the future. He will buy Liberty Bonds and keep out of danger. But who will make the munitions under such circumstances? There is but one reply—the Government. It is inevitable that when the Government gives the manufacturer a minimum of profits and lets him shoulder the losses unassisted, no one will want to undertake the risk. In Great Britain the outcome of high taxes on necessary industry has been Government factories.

* * *

IF, HOWEVER, any industries should be marked out for destructive taxation, clearly those chosen should be the luxury industries. Obviously the manufacturer of unnecessary articles should pay the higher tax, and not those war industries which are performing an essential service.

There is a large degree of Bolshevism abroad in this and other lands. It existed long before the word Bolshevism was coined, and long before the war commenced in Europe. Great Britain has been affected by it from the start. The belief was that commercialism started the war and that the gun factories and steel industries desired the struggle in the hope of enriching themselves. What more natural decision, then, than that which was made—the decision to prevent these industries from profiting by the war they were alleged to have started?

Even though the Allied governments knew that the industries were not guilty, yet it seemed necessary to appease those who believed with the fervor of fanaticism that the guilt was proved to the hilt. The politicians, especially in Great Britain, well argued that they could not save their faces if the war industries in the warring countries profited generously from the struggle.

* * *

SO THE burden of taxation was put on them, though these much abused industries were the nation's real defenders. In fact nothing was more necessary than that they should increase in numbers and activity. To this end it was needful that they be enabled to secure capital. Strange to say, a fair profit does not insure the rapid growth of an industry, for an industry grows almost wholly from the inside outward.

A man whose business it is to sell ribbons will not enter the steel industry no matter how prosperous it may be. He may invest a little money there, but industry chiefly grows from the reinvested earnings of its own capitalists. They have the knowledge needed and they desire to invest their money in their own industry. Tax that industry higher than other industries and you not only remove the means for expansion from the industry in question, but you make the capitalist leave the essential industry for one less essential and thus your Bolshevism proves to be your undoing.

* * *

AS FOR the taxes on luxuries that have been proposed, they are, perhaps, desirable; but more important are taxes on the profits of those industries that manufacture luxuries. So long as luxuries are advertised they will be sold. It will be represented that the spirits of people must be stimulated, that the home fires must be kept burning, that good cheer is as important as military service, and every possible excuse will be made for the unnecessary expenditure of money.

Over-tax the luxury industry, and the luxuries will cease to be flaunted in the eyes of would-be buyers, and the public will give them up without a qualm. The home fires will burn just as vigorously and on less expensive and less labor-wasteful fuel. The luxury advertising of the luxury producers is the cause of half our heartburnings, and it acts as a diabolic reproach to every one who has loaded up on Liberty Bonds and paid generously to the Red Cross. "The sacrifice," it seems to say, "was not necessary. Only a happy, well-fed, prosperous family at home will be able to hearten the warrior for the fray, and here you have been skimping till your heart is dead within you. Cease saving for Liberty Bonds. Buy a piano-player on time."

THE luxury trade shouts from every car advertisement and shop window that the army needs your spirit as much as your money. Fine clothes tone up the spirits; a bracing trip in an automobile elevates the flagging heart; a trip to Palm Beach renovates a run-down system, and so on.

Tax the luxury industry and you will remove such temptations and allay a large amount of discontent. What reason is there that in a world war unessential industries should be the only ones free from price regulation? What logic is there in permitting them to be exempted from special taxation? Their prosperity is certainly as conspicuous as that of the war industries; in fact it seems far more conspicuous and less justifiable.

Reasons for the defense of these industries from taxation and control are not so much reasons as excuses. Patriotic people are trying to avoid investment in luxury trades. When investors improperly succumb to the temptation that the large dividends paid by these stocks afford are they to be further enriched by the action of the Government itself, which apparently favors by exemption the luxury industry whenever a decision has to be made as to where the burden of taxation shall lie?

Lantern-Slide Talks for Mine Workers

MANY things to which an operator is entitled he does not get. The workman does not deny that the operator is entitled to them, but because the workman is not trained the operator does not get them. One of these things is a reasonable protection against the fire hazard. The workman knows he should not burn down his employer's property. Incendiarism is usually farthest from his thoughts. Yet because the employee has not been trained to avoid fire hazards the property of the operator is subject to many unnecessary risks. Would it not pay to give the workman and his family training that would make this hazard less menacing?

A little book on "Safeguarding the Home Against Fire," prepared for the United States Bureau of Education and written by the National Board of Underwriters, has just come to the editor's desk. It has 91 pages of excellent type matter, with cartoons which would make appropriate lantern slides and serve as cues to a good lecturer, such as every large mining town should have.

Freedom from accident is another right of the employer. He is, or should be, trying to secure safety. Why should the employee in many cases be creating and not removing hazards? No invidious criticism is intended or even justified. Neither employer nor employee is any too clear about his whole duty to safety. But in the work of securing it lantern slides and a lecturer is the appropriate medium.

Unfortunately lecturing skill is rare, but that is largely due to the lack of opportunity. So few of us have any chance to practice oratory unless we are labor leaders, politicians or lawyers. These people soon develop into real orators, and there is no reason whatever why an engineer cannot be brought to do the work successfully. Unless he is constitutionally ill fitted, he is a good man for the job. Not being in administrative control of the men he is usually in better accord with them than the manager can well be.

Some One Should Make a Start

THE anthracite operators and the Fuel Administration seem to be drifting onto the sunken rocks of the army draft for lack of a firm hand on the rudder. It would be better by far to stop the miners of the hard-coal region from joining the army than to bring them back, as Great Britain did, from the trenches in France.

No one seems to want to draw odium on himself by opposing the draft of these much needed men. Everyone acknowledges that they do a larger work in the coal mine than they can ever hope to do in France, for without coal we might as well give up the struggle. It is also well understood that the culm banks are shrinking and will soon cease to make up for the shortage in the coal mined from the face. But everyone is waiting for someone to rise who will take the burden on himself of making the unpopular proposal that anthracite mine workers be exempted.

Another bold spirit is needed—someone who will ask for the repeal of the Gallagher bill so that men with a few days of intensive training can be placed in charge of a mine breast, as is customary in bituminous mines. No American wants to work two years under a foreigner as a common laborer, especially an uneducated foreigner, and the law is keeping Americans and the better type of foreigner out of the mines.

The act was planned from the first to limit the introduction of labor into the anthracite fields, especially during a strike. It has done that work admirably, but we doubt if at the present any patriotic American, miner or other, feels any admiration for a law which keeps our mines short-handed in the face of the enemy.

The trouble arises from the fact that the Gallagher bill was passed after a long fight. It is a labor trophy, but like the cups and medals won in past contests it must now be cast into the melting pot. There are lots of men around the mine workings and elsewhere who could readily be transformed into miners if the law were modified. We are not at all convinced that there would not be fewer accidents, because in general a greater sobriety and carefulness mark the day worker.

It would seem that the matter of excluding miners from the draft and modifying the Gallagher act should be tackled by the Fuel Administrator himself, with the assistance of John P. White. There are no strikes to break up, and if there were the Gallagher act could be restored to meet such an emergency. Why not pass an act permitting the Governor to suspend the Gallagher act at his pleasure during the continuance of the war? The legislature would take such action if requested by Doctor Garfield.

Furthermore, the draft boards would refuse to accept miners if the Fuel Administration made it clear that acceptance jeopardized the fuel situation and that the prosecution of the war would be seriously hampered if the hard-coal supply failed. But so long as the highest authority is silent as to the necessities of the case, no wonder the legislators and draft officials are in doubt. Some one must take a place at the wheel before it is too late, and the man of all men seems to be head of the Fuel Administration. It is gratifying to read that Doctor Garfield has already taken some steps and that operators, draft officers, mine workers and the public are being gradually aroused to the great necessity.

Uncle Sam is Commandeering Steel

UNCLE SAM TO THE STEEL PRODUCTS CIVILIANS:
"Some of you will have to fall in behind the boys at the camp, so get busy!"

If we don't want to use wood rails and wood ties, we must take good care of the steel rails, steel ties and steel spikes now around the mine. Keep them out of sulphur water and lift them before the roof falls on them.

DISCUSSION BY READERS

Waste in Lubrication

Letter No. 1—In frequent visits to the different coal fields I have been struck with what, to my mind, is a serious detriment to the successful operation of any coal mine, to say nothing of the great waste of material and machinery that results from a practice that is inexcusable from the standpoint of efficiency.

In this letter I will confine my remarks to one subject only, regarding which all practical mining men will admit there is an unwarranted waste; namely, the lubrication of mine machinery and equipment. In the large majority of mines this work is done in the most slovenly manner. Not only is there a great waste of the lubricant, but efficient operation is impeded and loss inevitably results.

Before proceeding further, let me say that there appears to be a most woeful lack of information and, I may add, also, of intelligence on the part of many men in charge of mine operation and equipment requiring lubrication. I am at a loss to say whether the operating officials are more to blame in this matter than are the manufacturers of lubricants, for their failure to disseminate needed information in regard to the proper use of their products.

Recently, I observed a plant in West Virginia where the general superintendent, who is supposed to be a thoroughly high-grade man, compelled his employees to use a low-grade oil commonly known as "black strap" to lubricate, or I might better say, to *smear* the bearings of their mine fans, trolley locomotives, hoisting and winding engines, and mine cars. The use of such a lubricant takes one back several years in mining practice, when it was practically the only oil used about a coal mine, but which is today largely supplanted by higher-grade lubricants.

THE BEST EQUIPMENT CHEAPEST IN THE END

In my wanderings I have observed instances where air compressors have frozen stiff, because of the use of a wrong kind of lubricant. Hundreds of thousands of mine-car wheels have been gouged out in the hub, because of improper or insufficient lubrication. The purchase of any kind of cheaper lubricant other than that adapted to the purpose intended is the most expensive in the end. The best motor one can buy, the best type of mine-car wheel and bearings, will certainly fail when a proper lubricant is not employed, and the loss to the operator will often amount to thousands of dollars in a year's time.

The saving of lubricant at this time is a most vital question, inasmuch as the supply barely exceeds the demand. Yet when one goes about the coal mines it is a common thing to find the floor of the tipple, or the shaft or slope bottom, coated with the drippings from wheel hubs. At times the timbers will be covered almost an inch thick with a cake of the lubricant, which has become mixed with the dirt and dust of the mine and hardened. Likewise, the cars, wheels and axles are caked with the same deposit, which means not only a waste of lubricant but a loss of power in hauling trips.

While such conditions prevail at a large number of mines, the same is not true at mines where the management has given more attention to the selection and use of a proper lubricant. In the majority of such cases I have found that the mine cars in use are equipped with roller bearings, which permit of the use of a higher grade of lubricant. The use of grease to lubricate this type of bearing avoids waste both of material and labor in its application. At such mines it is rare to hear of a bearing giving trouble.

Believing that this is a vital question in mine management, I hope that it will receive the attention it merits and be discussed by practical men who can throw much light on the subject by giving their experience in the lubrication of mine equipment. OBSERVER.

Pittsburgh, Penn.

Gathering Motors

Letter No. 5—Perhaps *Coal Age* can find space, in its interesting columns, for another letter on the subject of gathering motors, from a man who has tried all three of the types of locomotives mentioned in previous letters.

Before coming East in the employment of the Fuel Administration Board, I had charge of a small mine in Pennsylvania, where, a few years ago, a trolley locomotive was installed to take the place of mule haulage on the main roads. We still used mules for gathering coal at the face, but found that the new machine greatly accelerated the work of hauling the coal out of the mine, and I felt that we had made a step forward.

It was with much pride that we watched the trolley locomotive, the first day, as it rolled into the mine, only to emerge a little later with a loaded trip of cars. Every man in the mine was glad to be rid of the troublesome mules, on the haulage roads, and the advent of the locomotive in the mine was hailed gladly and quickly proved to be an efficient part of the equipment.

Two years went by, and I began to consider a further improvement of the haulage system, by the adoption of complete motor haulage, from the face of the coal to the tipple. After a little investigation, naturally, the storage-battery locomotive appealed to me as the best type of machine for this work, because of the ease with which it could enter the low workings.

Someone now told me, however, that battery locomotives were not economical on long hauls with heavy loads; and, regarding it as impracticable to extend the trolley system to the working faces, I compromised and bought a combined trolley-battery locomotive, being fortunate enough, as I then thought, to sell my trolley locomotive at a good figure.

As time went on, however, results convinced me that I had made a mistake in the choice of this machine, which was fast proving a disappointment. As has been explained clearly by the writer of Letter No. 3—the man with a distinguished name—while the battery locomotive is theoretically ideal, in mine haulage, certain electrical considerations and requirements make its use unpractical. I learned by experience that these two types of locomotives cannot be combined without a serious sacrifice of the good qualities of both types.

A year passed, and I became convinced that it was necessary to take further steps to improve the haulage system in our mine. I removed the batteries from the machine and replaced them with pig iron to give the necessary weight to enable the locomotive to haul its load. I then used the machine as a trolley locomotive, on the main road only, and bought two small storage-battery locomotives for the gathering haul. These machines proved very efficient as they could go wherever track was laid, without the expense and labor required to install a trolley system.

The trolley locomotive operating on the main road handled heavy trips that would have drained the batteries had they been employed to supply the power. My story may seem long drawn out, but I believe that there are many other operating men in charge of small mines who must find by experience, as I have done, what equipment is best suited to the conditions in their mines. There was one further development that was important as it has proved by several years of successful operation to have effectively solved the haulage problem in that mine.

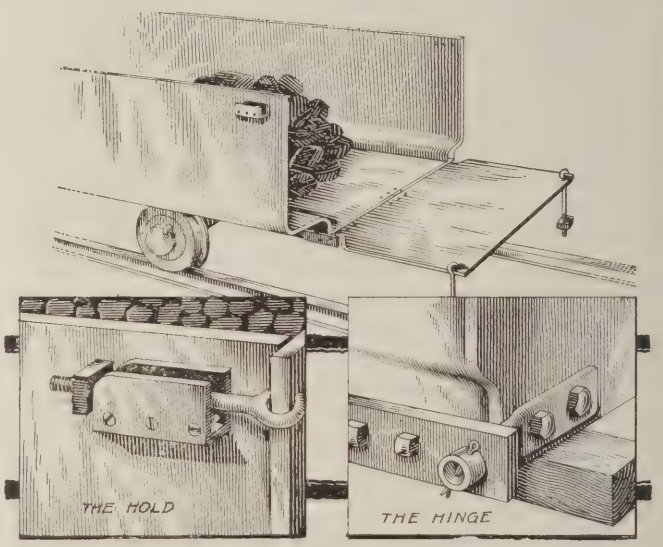
Advantage in Roller-Bearing Equipment

Having heard that a neighboring mine was using storage-battery locomotives, not only for gathering cars at the face, but for the complete haul, from the face to the tipple, I went to the mine to see what type of locomotive they were using that would stand up to that work an entire shift without midday charging. Much to my surprise, I found that they were using the same make of storage-battery locomotive that I had installed at our mine.

Further investigation showed, however, that their mine cars were equipped with roller-bearing wheels, which enabled the locomotive to make the long haul without a serious drain on the batteries. The superintendent told me that he had never found it necessary to charge the machine except at night.

Impressed with these results, I returned home and began at once to make the change from plain bearings to roller bearings, on a few cars at a time. The result is that my two storage-battery locomotives, today, are performing successfully the entire work of hauling the coal from the face to the tipple.

The experience I have narrated convinced me that where the mine cars are equipped with roller bearings, a storage-battery locomotive can be used to haul the coal from the face to the tipple more economically and conveniently than any other type of equipment. Let me say, in closing, that practical mining men should be encouraged to give their experiences in these columns which cannot fail to be of interest and profit.



Bayshore, L. I. Steven D. Otis.

Mine-Car Door

Letter No. 1—Replying to the inquiry of V. C. Robbins, *Coal Age*, June 1, p, 1031, kindly allow me to present the accompanying sketch showing the door end of a mine car that may possibly answer Mr. Robbins' purpose and solve the problem he has put up to *Coal Age* readers.

No definite measurements are given in the figure, since the plan submitted is a general one and can be applied to most any low-seam car, with slight change if that is necessary.

As shown in the figure, the door is hinged at the bottom, swinging on an iron bar or steel piping. The details of this are clearly shown in the figure. The two ends of the bar or pipe on which the door swings pass through holes drilled in stout pieces of strap iron and a

DETAIL OF CAR DOOR IN LOW SEAM

cotter holds it in place. The door is further strengthened by an iron strap passing around the bar and bolted to the door at the center.

When the door is raised, it is held in position by a latch on each side of the car. This is an eye-bolt and nut, the eye being bent through a hole in the door, as shown in the figure. By adjusting the nut on the bolt the door can be brought snugly against the end of the car. This arrangement may seem to be crude, but it has proved satisfactory in our case and costs very little to install. H. J. Tracy.

Lakewood, N. J.

[The arrangement proposed by this correspondent is a simple device, but does not provide for the automatic releasing of the door when the self-dumping cage reaches the top of the shaft, as specified by Mr. Robbins in his inquiry. Some of our readers can possibly improve, in other ways, on this arrangement and we hope to hear from them.—Editor.]

Letter No. 2—The inquiry of V. C. Robbins, in regard to a mine-car door that will permit a car to be loaded through the end gate, in working a low seam of coal where a self-dumping cage is used in the shaft, reminds me of a similar instance in my own experience, at a shaft mine of which I had charge.

In that case, we experienced a good deal of trouble from the coal falling back down the shaft when the car was tilted to dump the coal into the screen chute. I may say that, in one day's average run, from 3 to 4 tons of coal had to be cleaned out of the shaft bottom every night.

The miners, of course, loaded mixed coal, large and small sizes together. The style of the cage, which was self-dumping, was the "drop-bottom" type and, as I said, much coal fell into the shaft. We tried various schemes to overcome the difficulty; but still a considerable quantity of the fine coal and slack would find its way into the shaft when the cage was dumped; and it had to be cleaned out once a week.

Double Doors for an End Gate

Finally, I concluded to try a new kind of end gate that I believed would be more suited to a self-dumping cage. Instead of a single door or end gate, I proposed to use two half-doors, each swung on hinges from the side of the car. When closed, the doors would be locked with a catch that could be knocked loose by an automatic arrangement similar to that in use at the present time.

As the cage was tilted, the catch was loosened automatically and the doors swung open each way from the center and prevented the coal from dropping into the shaft, as it was prone to do when the old style of end gate was used.

It may be suggested that the two half doors swinging outward would strike the bottom of the chute when the cage was tilted to its full position. This was obviated, however, by cutting short narrow slots in the floor of the chute into which the ends of the doors sank. The slots were sufficiently wide to allow the doors to fall into them readily and an apron below caught what fine coal went through the slots. The scheme worked fairly well.

Since Mr. Robbins states he is loading only hand-picked coal in the cars, there may be little trouble experienced with coal falling back down the shaft in the manner I have described. Still, I thought the scheme of dividing the end gate in this manner was worthy of mention.

R. W. Lightburn.

Perryopolis, Penn.

Gas Encountered Reopening Mine

Letter No. 1.—In reading the inquiry of J. M. Kemp, who describes his experience in reopening an abandoned mine that had filled with water, *Coal Age*, May 11, p. 894, I was both interested and surprised. Mr. Kemp states that, after pumping out the water he encountered gas that gave a 4-in. cap on a Wolf lamp, but would not explode though the flame was much disturbed in the lamp. He states that he even attempted to explode the gas by black powder, but failed.

To my mind, it is fortunate for him and his companions that the attempt did fail and, to this fact, they probably owe their lives. The first advice I want to give our friend is: Never again attempt to explore an old mine under the same conditions; but, first use some means to obtain a current of fresh air and conduct it into the mine by erecting a brattice in the slope. Permit no one to advance ahead of the fresh air. It would seem that in the former working of this mine, some means must have been employed for its ventilation, although it is stated that there was but one opening, which made it necessary to start a second slope.

Assuming, however, that no available means of ventilation was found, and that it was necessary to ascertain if the mine would warrant being worked, before going to the expense of installing ventilating apparatus, some inexpensive method should have been adopted. For example, it would have been a simple matter to have erected a wooden chimney, say 15 or 20 ft. in height, on one side of the slope mouth and connect this with the brattice forming a return air space in the slope. The cost of doing this would have been small and it would have provided an air current sufficient for the exploration of the mine.

Strange Adventure in a Gas-Filled Mine

What appeals to me as strange is that one could proceed into a mine "a half mile," after having observed a 4-in. cap in his lamp when passing down the slope. In my opinion, there were grave chances of the men being trapped and unable to get back. This may seem harsh criticism, to Mr. Kemp, but it appears to me that he undertook a very foolish task and one that ought not to be repeated.

The explanation given in the reply made to this inquiry is enlightening as to the character of the gas and the reason why it did not explode. However, I understand that a 4-in. gas cap, on a Wolf lamp, indicates approximately 12 per cent. of marsh gas. Then, taking the explosive range of this gas as varying from 7 to 16 per cent. when the oxygen content is normal, it would seem to indicate that the mine air in the slope where the lamp showed a 4-in. cap was highly explosive.

Effect of Lack of Oxygen in Mine Air

It appears to me that the fact that it was not explosive can only be attributed to an insufficient supply of oxygen, owing to the presence of an excess of nitrogen or carbon dioxide in the air. It may be assumed, from Mr. Kemp's description, that there was an excess of both of these gases, which would reduce the oxygen content.

But, when the oxygen in the air is reduced to 15 per cent., lights will not burn; and as Mr. Kemp's light was not extinguished, there must have been at least 15 per cent. of oxygen present together with the 12 per cent. of marsh gas indicated by the 4-in. cap, which would leave 73 per cent. of nitrogen and carbon dioxide in the air. This would be a very dangerous atmosphere to breathe.

It has been explained, in the editor's reply, that flashdamp produces a gas cap that disappears quickly and the lamp flame, is dimmed or may be entirely extinguished depending on the purity of the flashdamp mixture. Mr. Kemp says, however, that the flame cap decreased in height the further he went into the mine until he was forced to turn back.

It seems to me that the cause of the gas cap diminishing the further the lamp was carried into the mine,

and the reason the lamp did not explode, were chiefly due to the lack of oxygen in the mine air, whether this was caused by an increase of nitrogen or of carbon dioxide. JAMES TOUHEY.

Cumberland, B. C., Canada.

[Our correspondent is wrongly informed in regard to the percentage of marsh gas indicated by a 4-in. cap on a Wolf lamp. When testing with a reduced flame, with the Wolf lamp burning naphtha, a 4-in cap would indicate about 4½ per cent. of marsh gas present in the air, assuming a normal oxygen content. With a normal flame, 6 per cent. of gas will cause the flame to reach a height of 3 or 4 in. and be greatly disturbed, twisting about in a weird manner when the oxygen content is normal.

The presence of more or less carbon dioxide in the mine air, as in the case mentioned by Mr. Kemp, has the effect to dim the flame and shorten the duration of the gas cap produced. The amount of the dimming of the flame and the duration of the cap will depend on the purity of the flashdamp mixture, as we have stated on page 894, in reply to this inquiry.

Both nitrogen and carbon dioxide are extinctive gases and their presense in the air causes the depletion of the oxygen. It makes little difference, therefore, whether the effect be ascribed to a low oxygen content or an increased percentage of either of these gases.

While nitrogen is a neutral gas, having no toxic effect, carbon dioxide has a distinctly toxic effect; but both of these gases have practically the same extinctive effect on a flame. The characteristics of flashdamp will vary with the constitution of the mixture or the percentage of noxious gases present.—Editor.]

What Caused the Explosion?

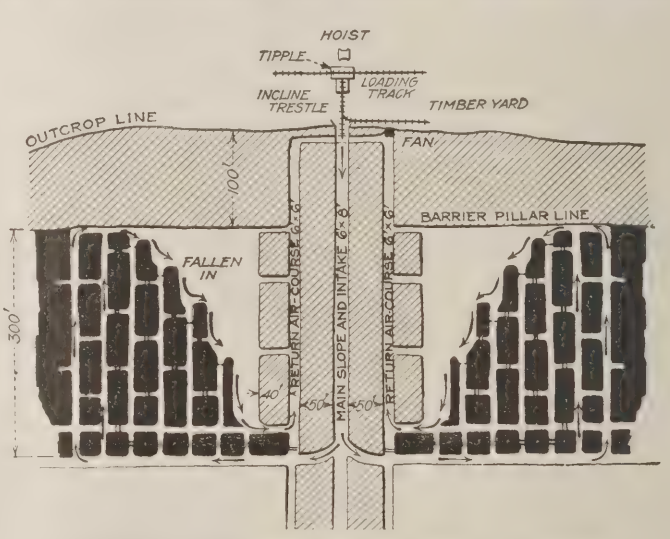
Letter No. 3—In seeking for the cause of the explosion mentioned in the inquiry of "fireboss," *Coal Age*, Apr. 6, p. 645, I favor the suggestion made by Oscar Jones, Apr. 20, p. 755; namely, that there probably existed gob fire in some portion of this mine and that this was directly responsible for the ignition of the gas, which it is very natural to suppose accumulated during the period of idleness.

The existence of a gob fire, in this mine, seems all the more reasonable to suppose, because the place where the explosion started is described as the old workings that were wet. Now, since it is stated that "the mine was ventilated wholly by natural means, there being no fan or furnace," it strikes me that these conditions were very favorable to the production of a gob fire.

Especially would this be the case if there was some fine coal and slack mixed with the slate, in the gob. The heating of the gob, under the slack ventilation in the mine, would generate carbon monoxide, which would greatly assist the starting of a gob fire.

From the question of "fireboss," as to whether this was a gas or dust explosion, it is natural to assume that the mine was somewhat dusty; and that, in addition to the gas which evidently accumulated in the old workings while the mine was idle, made the conditions very favorable for the explosion of the gas and dust that I assume and believe was ignited by the fire burning in the gob.

In my opinion, the dust factor is not a slight one, since a small percentage of dust thrown into the air by the first explosion of the gas would generate a dangerous condition for the propagation of the explosion, which might otherwise have been local in its extent. It is my belief that this was both a gas and a dust explosion combined. GASTON LIBIEZ.



Peru, Ill.

Working 10-Ft. Inclined Seam

Letter No. 5.—A large recovery of coal at a low mining cost, in the 10-ft. seam inclined between 15 and 20 deg., described in the inquiry of "Superintendent," *Coal Age*, Mar. 23, p. 561, will prove a rather difficult problem. The cost of the operation will naturally be the deciding factor in determining the completeness of the extraction or, in other words, the amount of coal that must be left in the ground.

Because of the disturbed conditions in this seam it will not be possible to follow a rigidly uniform system of mining. The success of the undertaking will depend, to a large extent, on the roof coal that must be left up in the first working for the support of the frail stratum overlying the seam.

In considering such a proposition, I would be inclined to estimate on a 400-ton output and assume the worst conditions existing underground. The seam being badly faulted, it will be useless to open wide places. In the accompanying figure is shown the general plan

WORKING THE COAL ON THE PANEL SYSTEM

that should be followed. This consists in driving a single slope on the full dip of the seam. The slope should be 6 x 8 ft. in the clear, after being timbered with 14-in. timber sets spaced 5 ft. centers and lagged with 6-ft. lagging, which will permit of a 6-in. overlap above each timber set. In order to secure a uniform grade when driving the main slope, the line of the slope should be previously prospected by drilling, so as to permit of the construction of a profile for determining the grade of the incline.

When the slope has reached a sufficient depth to provide for a 300-ft. lift below the crop-coal barrier, gangways should be started to the right and left of the slope. As shown in the figure, these should be turned off on an easy curve so that the loads will have

a straight pull as they reach the heavy grade of the slope.

As appears in the figure, a 6 x 6-ft. air-course is now driven up on each side of the main slope, starting from the gangway and leaving a 50-ft. pillar of solid coal, or whatever the state law may require, between the slope and each airway. There should be no cross-cuts driven in these pillars; but ventilation should be secured by the use of flexoid tubing while driving the main slope and the air-courses. When near the surface the air-courses must be connected by driving a crosscut under or over the slope and leading to an exhaust fan.

The gangways should be driven 8 ft. wide and 7 ft. high, taking up enough of the footwall, on the rise side, to bring the floor of the seam just above the top of the car. A low car should be used, having a capacity of 3000 lb. of coal. Chutes are then driven to the rise of the gangways, on 30-ft. centers, 8 ft. wide and from 4 to 6 ft. high. About 7 yd. up from the gangway the first croscut or counter is driven between the chutes and made 6 x 6 ft. in section.

Construction of the Chutes

Three rows of props are carried up each chute, the timbers being spaced 4 ft. apart center to center. The middle row should be placed 30 in. from the inside rib row. On two of the rows, nail 2 x 6-in. strips 8 ft. long, to which can be spiked No. 18 sheet iron, 30 x 96 in., so as to form a trough in which the coal will slide to the gangway. Boards 1 x 12 in. can be used for the sides of the chutes. This system requires "bucking the coal," which, if dry, will slide freely on this pitch.

When the chutes have reached the top, bring back the full width of the pillar, or 11 ft. on each side of the chute. When drawing back the pillars only sufficient timber should be used to properly control the roof weight, which will serve to break the coal as quickly as it can be mined and removed. With proper care, the caving of the roof should not be dangerous on this pitch.

A single-drum hoist should be employed capable of hauling two- or three-car trips up the main slope to the tipple. Each trip should be pulled into a rotary dump and the coal dumped into the loading chutes, without uncoupling the rope from the cars. A back switch at the foot of the trestle will enable the handling of supplies from the ground level. Provision should also be made to handle cars loaded with rock, as there will be considerable refuse of this kind to be hauled to the surface. The mine should be equipped with an air compressor having a capacity of 500 cu.ft. of air per minute for operating drills and jackhammers.

Delmar, Ore. SUPERINTENDENT.

Miners and the War

Letter No. 11—The great organized body of the United Mine Workers of America, enlisted so largely in the service army of Uncle Sam, should know and realize their responsibility in the great struggle for democracy in which they form an element as important as the soldiers in France who are working night and day and fighting with magnificent courage. The duty of the one section of this great army of workers is to supply the material that the other needs and must use. The army at home must supply the fuel that gives power to the army in the field.

This is a war of the people and concerns every individual citizen. Upon its issue hangs not only the future of this country but that of the world. The battle is on and must be fought with every energy at our command. Success on the firing line depends on the earnest and effective work at home. Life is the last full measure of devotion that our brave boys in France are offering for their country, and all they ask is the needed support and backing at home that they have the right to expect. United action at home means decisive results on the field of battle.

Responsibility of Home Workers

The great army of mine workers are being put to the test to prove whether or not they possess that spirit of loyal devotion that shall enable them to stick close to their work and produce the coal that is sorely needed in abundance to help us win the war. America has lifted high the ideals for which it is fighting and now looks to its army of industrial workers to strengthen the sinews of war and make it possible to banish forever the autocratic power that has come to be known as "Kaiserism."

The responsibility rests upon every individual, as well as upon every organization of men, to advocate the necessity of an increased production of the munitions of war. We must maintain a deaf ear to the German propaganda with which the Kaiser has assumed to attempt to tie up our industries, and thereby to paralyze the efforts he has been so loath to believe that America could or would put forth in the great struggle in Europe. He has hoped to block our railroads and prevent the sailing of our ships by sapping the work in our coal mines and cutting down the production of coal.

An Appeal to the Loyalty of Miners

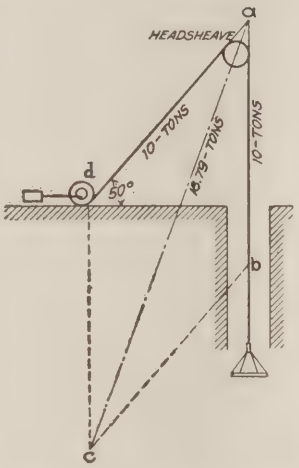
To the miner, let me say, Stop, look and listen! Think of the vital importance that an increased coal production is to our country and future life. Upon the miners of America devolves the sacred duty of keeping alight the torch of liberty, which alone can insure justice and peace throughout the world. In the struggle for democracy, let us not falter or count the cost, but work and strive for the preservation of American liberty.

The best news that we can send to our boys in France is that we are behind them to the last minute of the last hour, in thought, word and deed. Knowing this will inspire them with new courage, strength and confidence, and victory is certain.

It is my hope and belief that the great army of mine workers, 400,000 strong, will stand by their guns and keep the coal moving. It is only in this way that we can avoid the future necessity of maintaining an armed force for defense against the incursion of the enemy. Prussianism must be forever put down. Let us live up to our behest that "all men are created free and equal" and continue to live and let live; but, to do this, we must do our part in the struggle in which we are engaged, and our work at home, as miners, is to increase the production of coal.

Plymouth, Penn. JOSEPH R. THOMAS.

INQUIRIES OF GENERAL INTEREST



Load on Headsheave

Kindly show me how to calculate the load that is exerted to break the axle of a headsheave when the load on the hoisting rope is 10 tons, including friction, and the rope leading from the winding drum to the headsheave makes an angle of 50 deg., with the horizontal.

MINER.

Cumberland, B. C., Canada.

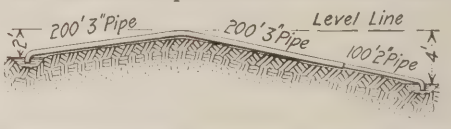
Referring to the accompanying figure, which shows a load of 10 tons supported by a hoisting rope in a vertical shaft, it is evident that, since the rope passes over the headsheave, the load on each branch of the rope is equal and a force of 10 tons is likewise exerted at the circumference of the winding drum.

LOAD ON HEADSHEAVE

In order to calculate the resulting load on the headsheave, extend the lines of each branch of the hoisting rope, until they meet at *a* above the sheave. Then, from that point lay off, to any convenient scale, the distances *ab* and *ad* to represent 10 tons each. Now, complete the parallelogram of forces *abcd* and draw the diagonal *ac*. The length of this diagonal, measured by the same scale as previously employed, will give the load on the headsheave or the load tending to break the axle of the sheave. This load is calculated as follows:

Since the rope leading from the drum to the headsheave makes an angle of 50 deg. with the horizontal and the other branch of the rope is vertical, the angle between the two branches of the rope is the complement of 50 deg. or 90 — 50 = 40 deg. Again, since the load on each branch of the rope is the same, the resultant *ac* divides this angle equally, making the angles *bac* and *dac* each 20 deg.

From the principle of a parallelogram, $ac = 2ad \cos 20$ deg. Then, since *ad* is 10 tons and the angle *dac* is 20 deg., the load on the sheave is



$ac = 2 \times 10 \cos 20° = 2 \times 10 \times 0.939 = 18.78$ tons.

Blasting a Ditch in a Mine

Kindly advise the best method of dealing with the following proposition: We have a slope mine that was driven in about 200 ft. to a point where we encountered some water and made a small local sump. From this point the seam rises about 1 in. in 4 ft. It has been decided to drain this local sump into the main sump by digging a ditch, which will be 2 ft. or more deep, at the deepest place, and 120 ft. long. The bottom is hard and will have to be blasted. Our difficulty arises from the fact that the timber frames, made of 10 x 10-in. timber, are all set on mudsills 4 x 10 in., 9 ft. 4 in. long, and spaced 4 ft., center to center. The ditch must be dug under the mudsills. Can this be done without damaging the timber sets?

Burnside, Penn. GEORGE SMITH.

We do not think that it is possible to blast this ditch out of a hard bottom without disturbing the timbering, and would advise draining the local sump in some other way. It may be possible to siphon the water, which would be far easier to perform and cost less.

In the accompanying figure is shown a successful siphon line having a rise of 2 ft. and a fall of 4 ft., which is suggestive.

Will Carbon Monoxide Support Combustion?

I have just noticed two contradictory statements regarding carbon monoxide as a supporter of combustion. In the "Coal and Metal Miners' Pocket Book," ninth edition, page 350, this gas is described as a "colorless, odorless and tasteless gas." The statement continues: "It is combustible, burning with a light blue flame. . . . Also, a supporter of combustion, being the only mine gas that burns and also supports combustion."

On page 852 of the "Coal Miners' Pocket Book," eleventh edition, I find the folowing statement: "Carbon monoxide, formerly known as carbonic oxide . . . is odorless, colorless and tasteless, and supports neither life nor combustion. It burns with a bright bluish flame and is explosive when mixed with air in the proper proportions." Kindly say which statement is correct.

Cucumber, W. Va. A. G. JOHNSON.

Carbon monoxide (CO) contains no available oxygen and the gas cannot therefore be said to support combustion. A lamp flame introduced into an atmosphere of this gas unmixed with air, if this were possible, would be promptly extinguished. In this respect, the gas behaves the same as methane (CH_4). Both of these gases being explosive when mixed with air in proper proportion, and both being combustible burning in air with a pale blue flame, it would be difficult or practically impossible to introduce a lamp flame into an atmosphere of the pure gas, in either case.

The statement that carbon monoxide is an "odorless gas" is questionable, because the extremely poisonous character of the smallest percentage of the gas in air would make it difficult to judge of its odor or taste.

EXAMINATION QUESTIONS

Tennessee Mine Foremen's Examination, 1918

(Selected Questions)

Ques.—What are the esential elements to efficient mine ventilation?

Ans.—The velocity of the air, the quantity in circulation and the manner in which it is distributed and conducted throughout the mine are the essential elements of efficient ventilation. The quantity of air in circulation must be at least equal to the amount required by the mining law of the state. In addition to this, the quantity of air in circulation must be sufficient to dilute, render harmless and carry away any accumulations of gas and make the mine safe for work. The air current must be conducted so as to sweep the coal face in every working place, besides all void and abandoned places, falls and cavities where gas might accumulate. The main air current must be so divided as to distribute the air to each district of the mine according to its needs and reduce the velocity in each working place so that it will not inconvenience the men or render the place unsafe for work.

Ques.—What instruments are used to determine the condition, volume and temperature of the air current in a mine?

Ans.—The anemometer and a tape measure and watch are required to measure the volume of air passing in an airway. The water gage is used to determine the unit of ventilating pressure or the pressure in pounds per square foot causing the circulation. The hygrometer, or wet- and dry-bulb thermometer is used to determine the amount of moisture in the air and the temperature.

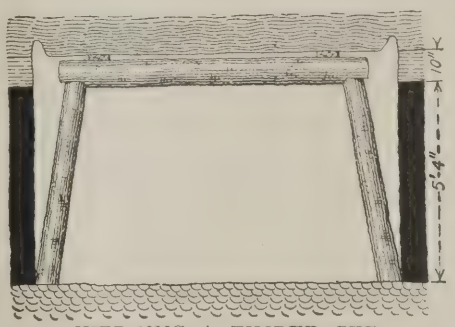
Ques.—Describe how the volume of air in a mine is correctly measured by the use of the anemometer.

Ans.—The instrument is held at arm's length by the observer and in such a manner that its vane will revolve in a plane at right angles to the air current A place is first chosen in the airway where the current will have a straight course and not be deflected unequally to either side, and where the sectional area of the passage can be accurately measured. An effort must be made to obtain as close an average reading as possible, according to the best judgment of the observer, after taking a few preliminary readings at different points in the cross-section. With watch in hand, the instrument is exposed for one or more minutes, and the reading of the dial taken before and after the exposure. From these readings is found the velocity of the air, in feet per minute. The sectional area of the airway, in square feet, multiplied by the velocity of the current, in feet per minute, gives the volume of air passing, in cubic feet per minute.

Ques.—In a mine where 275 men are employed, how many splits in the air current will be required according to law.

Ans.—The Tennessee mining law (Sec. 32) specifies that it shall be unlawful to work more than fifty men and eight mules in any single split or district, except where the judgment of the chief mine inspector decides it is practicable to do this. To work 275 men will therefore require $275 \div 50 =$ say 6 splits of air.

Ques.—At what points in a mine should air measurements be taken regularly, and how often?



Ans.—Sec. 24 of the law requires the mine foreman to measure the ventilating current each week, at places throughout the mine as designated by the chief mine inspector or the district inspector, and keep a record of the measurements in a book kept for that purpose.

Ques.—An airway 12.9 ft. wide and 8.9 ft. high is passing 50,000 cu.ft. of air per min.; what is the velocity of the air current?

Ans.—The sectional area of this airway is $12.9 \times 8.9 = 114.8$ sq.ft. The velocity of the air current, therefore, is $50{,}000 \div 114.8 = 435.5$ ft. per min.

Ques.—What is double timbering? Show by sketch how you would put up a set of double timbers, and how you would wedge them and why.

Ans.—By "double timbering" is understood a frame of timbers consisting of a collar and two legs supporting it. The manner of setting such a timber frame and wedging the same against the roof is shown in the accompanying figure. The wedges should be driven over the collar a short distance inside of the top of each leg so as to arch the pressure of the roof over onto the legs. No center wedge should be driven, the pressure would then break the beam.

WEDGING A TIMBER SET

Ques.—If you were taking air measurements at a mine and found 25,000 cu.ft. per min. at the intake, and only 4000 cu.ft. at the face, how would you account for this loss, and how can it be prevented?

Ans.—Assuming that the mine is ventilated by a single current of air, and the temperature of the mine air, at the face, is the same as that at the intake where the first measurement was taken, and assuming also there is no gas generated in the mine and no leakage of air through stoppings and doors, the quantity of air passing at the face should be equal to that on the intake. In this case, if there is but a single current, the loss of $25{,}000 - 4000 = 21{,}000$ cu.ft. must be attributed to a large number of leaky stoppings or a door partially set open. The mine temperature is usually somewhat higher than that of the outside air, and the rise in temperature, and the generation of mine gases in the workings, would increase the air volume.

COAL AND COKE NEWS

What Happened in May

[The bracketed figures in the text refer to pages in the present volume, reference to which will give fuller information regarding the matters discussed in that item to which the bracketed figures are attached.]

May 1—The 45c. allowance is conceded to the coal operators of Alabama, but will only be in effect from May 15, when the wage increase granted Apr. 21 becomes operative—The Department of Mines of Pennsylvania declares its intention to enforce the law prohibiting women from doing anything but clerical labor about the mines [841, 859, 886]—New prices go into effect in Brazil district of Indiana; in Montana; in Macon County, Illinois, at the mines of the Williamsburgh Slope Coal Co., Florence, Fremont County, Colorado; in Knox and Whittier Counties, Kentucky; and Campbell County, Tennessee [883]—A cave-in at the White Coal Co., Pittston, Penn., destroys 20 houses and kills one man and injures another [889]—Parrish Colliery breaker, now belonging to the Lehigh and Wilkes-Barre Coal Co., falls, but without casualties [889]—New concrete breaker is started by Delaware, Lackawanna & Western R.R., Coal Department, near Storr's breaker, Dickson City, Pennsylvania [946].

May 2—Railroad Administration announces that it has let contracts for the construction of 100,000 freight cars—Special convention of mine workers is held at Birmingham, Ala., to consider the recent wage increase tentatively accepted by the union officials for the mine workers in that state.

May 3—Special orders providing for the diversion of coal to New England, issued during the critical period of last winter, are revoked by the Fuel Administration [882].

May 4—First issue of "Saward's Journal," a coal trade weekly edited by Frederick W. Saward, former editor of the "Coal Trade Journal"—End of subscription period for Third Liberty Loan—Collision of cages in Loomis shaft of Delaware, Lackawanna & Western R.R., Coal Department [898].

May 6—Attorney-General Gregory condemns Prager lynching at American Bar Association Meeting.

May 7—Screened and sized crushed beehive coke in Colorado is set at $9.80 per ton by Fuel Administration—Order announced penalizing the New York and Philadelphia Coal and Coke Co. for providing low-grade quality of coal for the bunkering of a Belgium relief steamship—Albert H. Wiggin resigns as Fuel Administrator for New York State [883].

May 8—The shipment of coke produced in the New England States to points outside is forbidden except to Albany, Cohoes, Green Island and Troy, N. Y. No coke other than petroleum coke and crushed coke for domestic purposes may be shipped into the New England States from Maryland, New Jersey, New York, Pennsylvania and West Virginia [933]—Fuel Administration makes preliminary steps in fuel conservation by appointing Thomas R. Brown, of Pittsburgh, Penn., and C. P. Billing, a special staff assistant, to classify and rate plants as to their fuel efficiency [932]—C. P. White is appointed manager of Lake and Canadian coal distribution [932].

May 9—Representatives of the United States Steel Corporation and the independents meet with Samuel Gompers, president of the Federation of Labor, and other representatives of organized labor and the members of the United States War Labor Board, to discuss the principle of collective bargaining whereby the Government will be guaranteed against any interruption in the iron and steel industries during the war—The Fuel Administrator authorizes the employment of fuel inspectors for anthracite coal—George T. Watson announces that the Consolidation Coal Co. will put in force an equivalent of the Colorado Industrial Plan [934, 935, 976, 977]—All the mines of the Broad Top-Huntingdon field of central Pennsylvania but one are on this date found to be on strike [934, 976, 1022].

May 11—Prices changed for Wise and Lee County coal in Virginia and a price set for coke from the Howe plant of the Howe-McCurtain Co. in Oklahoma [933].

May 13—Shipment by way of the Great Lakes of smokeless coal from New River and Pocahontas districts in Virginia and West Virginia to Wisconsin, Minnesota, North Dakota, South Dakota and Iowa is forbidden where the fuel is to be used for domestic purposes. The sale, distribution and use of bituminous coal from Pennsylvania, Ohio, Maryland, West Virginia, eastern Kentucky and Tennessee, shipped by way of the Great Lakes, is prohibited in Illinois for domestic purposes [933].

May 14—Manager and a mine blacksmith are killed and three men injured by the explosion of a powder magazine at the Oliphant-Munson Collieries, Coal Spur, Alberta [987].

May 15—Meeting of operators of the Central West Virginia Operators' Association with a representative of the Fuel Administration. The Association agrees on behalf of its members to put the Colorado Industrial Plan into operation [976, 977]—New scale of wages goes into operation in Alabama [797].

May 16—Grievance strike at the Maxwell No. 20 colliery of the Lehigh & Wilkes-Barre Coal Co., at Ashley, Penn. [976].

May 17—Button strike at No. 5 colliery of the Delaware & Hudson Co., Larksville, Penn. [976].

May 18—Decision of Judge Henry in Dauphin County court in favor of three miners who had been docked for dirty coal. Susquehanna Coal Co. directed to pay them $350 [978]—Fire breaks through into the workings of the Peabody No. 2 North mine [1034, 1083].

May 20—Announcement is made that the railroads will spend about a billion dollars this year for additions, betterments and equipment, said to be approximately three times as much as in any of the last three years [1024, 1025]—Fire at gasoline fan in the mine of the Mill Creek Cannel Coal Co., at Villa, near Charleston, W. Va., smothers 13 men and does much damage [987, 1033, 1106].

May 21—National Retail Coal Merchants' Association holds its first annual convention at Atlantic City, N. J. [986, 987].

May 22—James Brothers colliery near Pottsville, Penn., closed down for shipment of dirty coal [1033].

May 23—The Fuel Administration requires that permission be obtained before opening a new mine and announces that it will require proof that the new mines will not secure laborers for opening and development from other mines and will not add to the difficulties of the Railroad Administration [1021].

May 25—Price of all bituminous coal reduced 10c. per ton, it being announced that the President has ordered the railroads to pay the Government price for coal [571, 779, 839, 885, 975, 839, 1020, 1025].

May 27—Freight rates on coal and other shipments raised roughly 25 per cent. by order of Director of Railroads, McAdoo and the Interstate Commerce Commission. Passenger rates are also increased to 3c. a mile. Railroad gross income should be increased $900,000,000 a year by the new schedules [932, 1020, 1021].

May 28—National Coal Association meets for its two-day session, and before it adjourns votes for incorporation [933]—John P. White is appointed a representative of the Fuel Administration on the Labor Policy Board [1025].

May 29—Fuel Administration prohibits use of coal or oil fuel after June 11 for private yachts except for the purpose of returning the yacht to its home port.

May 31—James M. Orr, president of the Orr Coal Mining Co., of Charleston, Va., charged with having secured an excessive price for coal from the Edison Portland Cement Co. and others, is fined $5,000.

Harrisburg, Penn.

The state compensation board has affirmed the disallowance in the case of Paolis vs. Tower Hill Connellsville Coke Co., in which the question arose whether payment of a hospital bill can be construed as payment in compensation when no agreement was entered into and the claims not made until a year after the accident. The decision was based on the time limit having expired. New hearings were awarded in the claims of Simurda vs. Lackawanna Ry. and Thomas vs. Aetna Explosive Co. In a dozen cases appeals were dismissed.

As a result of an investigation made by a special committee of the Scranton Board of Trade it has been learned that the mines in Lackawanna County are now working with 35,744 employees, almost 8000 less than the number needed to have the mines worked to their fullest capacity.

The investigation shows a big scarcity of laborers. When operated to capacity at least 8800 laborers are needed, but today finds only 4400 such men employed. The percentage of shortage in three branches is: Miners, 14 per cent.; company men, 7 per cent., and miners' laborers, 47 per cent.

Six Pennsylvania coal companies on June 7 asked the Interstate Commerce Commission for $250,000 damages from the Pittsburgh & West Virginia Railroad Co. They charge that the railroad unfairly gave mines, in the ownership of which it was interested, preference over the complainant in the distribution of cars from September, 1917, to March of this year, when they allege the discrimination was removed by the railroad administration.

William Potter, State Fuel Administrator, on June 1 cut the word "anthracite" out of the vocabulary of residents in 29 counties in Pennsylvania. In one of the shortest orders yet issued by the fuel administrator anthracite supplies were denied the following counties during the coal year of 1918-1919: Crawford, Warren, McKean, Potter, Tioga, Cameron, Elk, Forest, Venango, Mercer, Lawrence, Butler, Armstrong, Clarion, Jefferson, Indiana, Clearfield, Huntingdon, Blair, Cambria, Fulton, Bedford, Somerset, Allegheny, Beaver, Washington, Green, Fayette and Westmoreland.

These counties will be denied anthracite of domestic sizes, which embraces pea, nut, stove and egg grades. The principal reason given for the action was that these sections are in the soft-coal mining districts, where bituminous is the chief fuel burned.

Charleston, W. Va.

There was a material slump in coal shipped from the Kanawha district last week, the production being 141,272 net tons, representing a decrease compared with the previous week of about 13,000 tons, the decrease being due principally to an insufficient number of cars, the supply last week being only about 45 per cent. In other words, while the hours lost because of car shortage for the week ended May 25 was something over 800, the hours lost for the week ended June 1 amounted to 1605. Hours lost because of an inadequate labor supply totaled 357 and mine disability, or rather lack of power, was responsible for the loss of 274 hours. During the month of May the total loading for the Kanawha district was 37,620 as against 34,627 empties received, the car shortage for the month almost reaching 3000. Last Saturday, while the supply was almost equivalent to requirements, on Sunday 1227 cars were loaded out and only 868 received. On Monday 1427 cars were loaded out and only 893 received. On June 5 1360 cars were loaded out as against only 902 received.

Complaint is being made by many of the operators that while some of the larger mines are not receiving cars, yet the "snow bird" mines are receiving an ample number. Some of the operators are also at

a loss to understand why one mine in this territory supplying railroad fuel was able to load 4800 tons on Monday, 1630 on Tuesday, 1200 on Wednesday, 2200 on Thursday, 2240 tons on Friday and on Saturday last 1000 tons, when no one else on that day had any cars, it being regarded as a remnant of the old assigned-car system.

Conditions are even worse in the New River field, where the failure of the Virginian power company to supply the district with power is not only proving a blow to the industry but is materially interfering with war plans, since much coal from the New River section is bunker coal. Furthermore, it is defeating the effort to increase the total production for the year at a time when every coal operator is bending every energy to produce enough coal now to prevent a fuel famine next winter. Government agents have been investigating the power situation, but no action has been taken so far as is known here.

A slump is shown in the production of coal and coke in the Pocahontas and Tug River districts for the week ended June 1 due in large part to a shortage of labor, although cars are not as plentiful as they might be. A loss for the week ended June 1 of 26,137 tons is reported. The total tons produced amounted to 428,972. Car shortage was responsible for a loss of 158 hours, but labor shortage was responsible for a loss of 1013 hours.

Fairmont, W. Va.

The car supply in the Fairmont district, which is the Monongah division of the Baltimore & Ohio and the northern end of the Monongahela R.R., which is jointly operated by the Pennsylvania and the New York Central, had a good car supply all last week, with the exception of one day on the Monongahela, when a wreck tied things up. The Baltimore & Ohio car supply has been a full run for the mines, which are short of labor at this time.

Shipping facilities on the Kanawha & Michigan seem to be ample, though that road is much congested at this point owing to heavy Government traffic, affecting to some extent the ability of the Coal & Coke to accept empty coal cars for the mines on its line, since the capacity of the yard at this interchange point is limited. Under the rating of mines on the Coal & Coke between Charleston and Elkins the total number of cars to which all mines on the line are entitled is 259½. The development of mines on the Coal & Coke during the last year has been little short of phenomenal.

Plans to increase the efficiency of the mines are being discussed by the operating committee of the Central West Virginia Coal Operators' Association, and a program is being worked out by which meetings will be held at Fairmont, Clarksburg, Elkins and Morgantown, with the idea of having foremen and bosses gather together for talks which are inclined to cultivate efficiency and increase patriotism.

Terre Haute, Ind.

The car supply to Indiana coal mines for the week ended May 25 showed a further falling off, with a result of a loss of 107,005 tons. The per cent. of car shortage was 14.14 and the per cent. of time the mines actually worked was 75.52. There was hoisted during that week a total of 591,078 tons, according to reports to the district representative of the Federal Fuel Administration. The market for domestic coal continues to be large, but slowness of public utilities corporations to stock screenings is interfering with the marketing of domestic coal. As the market for mine-run continues strong, less screening is being done than could be done at this time of the year. The increase in freight rates, which amounts to 30c. a ton from the Terre Haute market to Chicago, is expected to stimulate the market for screenings during the coming weeks. If the public utility corporations do not start storage soon there will be a marked shortage of lump coal.

PENNSYLVANIA

Anthracite

Treskow—The slate banks, which consist largely of the smaller sizes of coal discarded for 50 years, will be loaded into cars by steam shovels and run through the Lehigh & Wilkes-Barre Coal Co.'s breaker at Audenried No. 4 colliery. Officials expect to retrieve thousands of tons of good anthracite coal out of this bank.

Pottsville—The Anthracite Consumers' League, through Frank C. Reese, on June 7 asked the Government experts, who started to check up accounts of coal operators, to pay special attention to the large profits on washery coal. This product is simply scooped up from culm banks and with little preparation is put on the market at the full price for freshly mined coal. They also ask the Government to reduce the price of coal from washeries.

Scranton—Charges that the Delaware, Lackawanna & Western R.R., Coal Department, is removing pillars on an extensive scale in its mine workings under West Scranton have been made in a special report filed with Council by City Engineer Long, who recently conducted a survey of the mine workings. He directly accused the company of bringing about recent costly caves through such action. Engineer Long stated that practically all of the pillars have been removed in the 5-ft. seam of the Hyde Park mine of the company under Grant Ave., and that the miners are removing others.

Bituminous

Phillipsburg—James Stratton & Sons, of Cuba, are now shipping coal from their new Pauline mine, near Osceola.

Connellsville—George W. Deeds, county commissioner of Westmoreland County, is opening a coal mine near Champion, in the Indian Creek Valley. Mr. Deeds purchased 50 acres of the Snyder farm.

Indiana—Mine Inspector Thomas S. Lowther, of this city, has announced the successful applicants at the recent mine foreman and fireboss examinations. The list includes five first-grade mine foremen, three second-grade mine foremen, eight first grade assistant foremen and eight firebosses.

Dixonville—The new mines of the Milbar Coal Mining Co. here have been sold to the Estep Brothers, of Lovejoy, who are operating a large mine here. The new management has increased the force of workmen on the new operation and expects to be shipping coal next month. The mine is located on the Clymer branch of the Pennsylvania and New York Central railroads.

Fayette City—"Black Row," a well-known section of miners' houses here, was destroyed by fire recently. The origin of the fire is unknown, but police are searching for one of the miners, in whose house the blaze started, as he is blamed by the other families with starting the fire. The houses were occupied by five families and were owned by the Pittsburgh Coal Co. Little or no household goods were saved by the occupants.

Indiana—The tipple of the Armerford Coal Mining Co., at Armerford, near here, was destroyed by fire on Monday morning about three o'clock. Ex-Sheriff D. E. Thompson, of Blairsville, president of the Armerford company, preferred charges aginst Martin Maloney, until recently the mine foreman at the Armerford mine, and Andy Smelke, formerly the assistant foreman, for arson. The trial will be heard at an early term of Indiana County court.

WEST VIRGINIA

Lillybrook—A new conveyor line is being installed by the Prince Wick Coal Co.

Rock Bottom—Another mine will be opened by the Rock Bottom Coal Co. as soon as a new power plant is installed.

Millstone—The Elkhorn Junior Coal Co. whose plant is near here, plans to begin the shipment from its mine within the next 30 days.

Point Pleasant—Half a hundred miners' houses will be built in the near future by the Mason Coal and Chemical Co. at Hartford, W. Va.

Amherstdale—A new mine in the No. 2 gas seam is being developed by the American Rolling Mill Co. of this place, under the direction of H. A. Jepson, general manager.

Lumberport—The New Superior Coal Co. is opening a mine to develop 66 acres between Shinnston and Lumberport. A tipple is being erected. The plan is to mine coal by July 15.

Dingess—New openings and haulways are embraced in improvements being made by Andrew Dingess, it being estimated that the capacity of the plant will be increased by 4500 tons when improvements are completed, giving the plant a total capacity of 20,000 tons per year.

Charleston—The Bengal Coal Co., with W. C. Robinson as superintendent in charge, has nearly completed improvements to its drift mine at a cost of $200,000 which will increase the company's output by 25,000 tons a year, giving the company an estimated capacity of 100,000 tons a year. Ten new miners' houses are under construction.

Logan—The McBeth Coal Co., of which John Laing is president, has awarded to the Dravo Construction Co., of Pittsburgh the contract for its new plant on Rum Creek, Logan County. The plant is to be most complete. There will be a slope of 400 ft. and a shaft of 100 ft. of a 5 ft. 4 in. seam of Eagle coal, the company holdings amounting to 1400 acres. In addition to the plant proper 30 four- and six-room houses for miners are to be built as well as a Y. M. C. A. clubhouse and a modern store and office building.

Kingwood—The Preston County Power Co. is an organization which will eventually have a plant near Trowbridge on the Morgantown & Kingwood R. R. for the purpose of maintaining a large central electric power station. The war interfered with putting the existing plans into effect, but the company is going ahead with its mining operations. I. B. Bowermaster, for many years superintendent of Elkins Mine No. 4 in that vicinity, now has the management of the plant. The men can work at the mines and live in Kingwood with present train service.

Fairmont—The South Fairmont Coal Co. which has a capital stock of $150,000, owning in fee 617 acres of coal land in Barbour County, near Century, plans early development. Application for sidetracks have already been passed upon favorably by the Baltimore & Ohio R. R. There are three veins of coal—the Mahoning, Upper Freeport and Kittaning. The Upper Freeport is the tipple-height vein, which will be developed first. The vein is 6 ft. deep at a wagon mine adjoining the tract. John W. Poling is president of the company, M. C. Lough is vice president, C. F. Crane is secretary.

Morgantown—Everything is in readiness for the opening on Monday, June 17, of the sixth annual short course in coal mining which is to be given at West Virginia University. Prof. A. C. Callen, head of the mining department, will be assisted by the mining extension instructors, D. H. Perdue, of Bluefield, and R. Z. Virgin, of Elkins. Mr. Perdue is well known to mining men, having been in the extension work for some time. Mr. Virgin, who came to the University in January, was formerly superintendent of mines for the Wheeling Steel and Iron Co. and is known all over West Virginia and Pennsylvania. An enrollment of about 40 students is expected, and the probability is that this number will be increased by late arrivals.

KENTUCKY

Middlesboro—The United States Coal and Coke Co., operating the Lynch mines at Middlesboro, has the distinction of leading the mines in that concern in the amount donated to the Red Cross, this mine having donated $11,650.

Richmond—Lee, Conley and Claude Congleton, of Richmond, who have been operating a coal mine at Chavies, Perry County, have sold the property to the Bewley, Darsh Coal Co., of Knoxville. The Congletons expect to start new developments on other property shortly.

Barbourville—The Manchester Coal Co. has begun operations on Horse Creek, Clay County, and expects to start running coal about Nov. 1. The company is incorporated with a capital of $40,000. The stockholders are: F. M. Maxey, of Barbourville; M. Miller, Lebanon Junction; W. C. White, Louisville; and L. R. Lam, of Greenville.

Frankfort—The Court of Appeals on June 4 held that circuit courts acting for miners and guardians cannot lease the mineral rights of infants' land beyond the time when such infants reach their majority, and held void the act of 1916 in so far as it granted the power and reversed the Pike Circuit Court in the case of the Tierney Coal Co. against Jake Smith's guardian.

Louisville—About 130 miners, representing almost as many coal companies, were recently in Lexington, where they took examinations in order to receive mine foremen certificates. During the time that the men were in Lexington they adopted resolutions, addressed to President Wilson, in which they pledged themselves to do all in their power to keep production of coal up to the maximum, and endorsing the war program.

INDIANA

Gary—The American Coal and Supply Co., with headquarters at Chicago, has been prohibited from selling coal in Gary, Hammond, Whiting, East Chicago, Indiana Harbor and other northern Indiana points by order of W. S. Fuer, federal fuel administrator of Lake County, Indiana. He alleges violation of Government orders.

Evansville—Matthew Duncan and son David, of Evansville, are engaged in sink-

ing several coal shafts in western and northern Kentucky. Many of the coal mines in the Green River country, in western Kentucky, are being reopened this summer and the coal is being hauled to Evansville on barges. Evansville capital is interested in the development of some of the Green River mines.

Petersburg—The Globe Coal Co., of Terre Haute, Ind., has purchased 450 acres of coal land along Sugar Creek in Pike County, Indiana, and will begin stripping the land to begin operations for coal. The coal tests showed a 5-ft. vein of coal at depths varying from 7 to 40 ft. The price paid was $100 an acre. Contracts have been let for ten new houses on Sugar Creek for employees to live in. The contract for the building of a railroad bridge across Patoka River, three miles west of Winslow, has been let, and also the contract for three miles of track.

Bicknell—The Vandalia Railroad Co. has begun, after the lapse of nearly a year, the double-tracking of its road between this city and Bushrod, a distance of 15 miles. With the extension of the five miles of track laid a year ago to the terminal at Bushrod, the railroad company can handle coal shipped from this city in a shorter time and without interference with passenger traffic. The new track will be ready for use, it is planned, by the time the busy season arrives again this fall. Day and night shifts are being used. The company has experienced great difficulty in securing men to do the work.

ILLINOIS

Clinton—The Illinois Central Railroad Co. has completed a new coal chute at its shops in this city. This chute is modern in every respect and will do several times as much work as the old chute.

Belleville—The first constitutional convention of the newly organized subdistrict No. 7, United Mine Workers of Illinois, will be held here June 17. Forty-five delegates will each represent 100 miners. Belleville will make a fight for the permanent headquarters of the subdistrict.

Carlinville—Test holes drilled on the farm of Mrs. Frank W. Burton, south of here, struck a vein of good quality coal 6 ft. 4 in. thick at a depth of 240 ft., with a satisfactory rock top. A local company has been organized by C. G. McIntosh to sink a shaft at once on the Teal farm just at the south edge of town to supply the local needs. A large acreage has been secured. The mine of the Carlinville Coal Co., which formerly supplied local needs, was sold last winter to the Standard Oil Co., which requires the output and that of three additional mines which are being sunk for its refineries. The local trade is being supplied temporarily, however, by the Standard people.

OHIO

Redfield—The Kehota Coal Co., organized about a year ago by Pennsylvania and Illinois capitalists, will soon start a stripping operation in the thin-vein Hocking district near Redfield. It is planned to have an output of about 1200 tons daily. All the machinery has been ordered and much of it is on the ground.

Crooksville—The C. M. Wilson Coal Co., of which C. M. Wilson is the head, will soon open a mine on the Toledo & Ohio Central near Crooksville. The company holds 106 acres of No. 6 seam at that place. The switch has now been completed and loading will start soon. The output will be sold through the H. W. Jenkins Coal Co., of Columbus.

MONTANA

Roundup—The contract for the construction of 25 four-room houses, a boarding house and other buildings at Mine No. 4 of the Roundup Coal Co., has been let and as soon as completed the company will put a large force of men at work on increasing the production of the mine. By early fall it is planned to turn out 500 tons per day with a probable production of 1000 tons. The present temporary tipple will be replaced by a permanent plant and additional mine cars and other equipment will be purchased at once. An additional electric hoist will be constructed also, and a second power line built.

WASHINGTON

Sedro Wooley—Development work on the coal mine at Cokedale near here has been completed by Superintendent Capt. F. A. Hill, who states that the property will be ready to ship out 300 tons per day as soon as the spur track being built by the Great Northern Railway Co. is completed. The mine will employ 300 men at the start. The property is leased by the Cokedale Coal Co.

Seattle—Fifty tons of the first Alaska coal sent to the outside from the Matanuska coal fields is being returned to the Northland to supply consumers in the Nenana Valley. The coal when it finally reaches its destination will have traveled something over 8000 miles, and yet as the crow flies those who will consume this coal are only 200 miles from where the coal was mined. So much for transportation facilities in Alaska. Owing to the long, hard winters and impassable trails between the Matanuska coal fields and Nenana, it was found necessary to ship the coal out of Alaska to Anchorage and from there to Seattle and thence by steamer to far-off St. Michael, there to be transshipped on Yukon River steamers to the Nenana.

Foreign News

Sault Ste. Marie, Ontario—The Algoma Steel Corporation has decided to further enlarge its byproduct coke-oven plant, and a contract for an additional battery of 25 Wilputte ovens has just been let to the Wilputte Coke Oven Corporation, of New York City, making 50 new ovens now in process of construction. It is expected that the two new batteries will be ready for operation late this year.

Granby, B. C.—Important progress has been made in the construction of a large coking plant, docks, sea-going vessels, a railway and other equipment on which much of $1,000,000 is to be expended by the Granby Consolidated Smelting and Power Co. At Graves Point the company has completed excavation for the coal bunkers and will start work on the superstructure at once. The bunkers will be 52 ft. wide and 300 ft. long and will have a capacity of 12,000 tons of coal. The coal will be transported by vessel from the mines on Vancouver Island, 400 miles distant, now being opened up by the Granby company. Besides coke to be used in its smelting operations the plant will produce gas, also valuable in smelting, and coal-tar products. It is estimated that the company will save 50c. a ton by the use of its own coke.

Obituary

Fred W. Nay, a successful coal operator of Shinnston, W. Va., part owner of the Hardesty & Nay Coal Co., succumbed last Tuesday in a Clarksburg hospital to injuries received in an explosion of a can of gasoline at the company's plant at Shinnston.

Coming Meetings

American Concrete Institute will hold its annual meeting June 24-26, at Atlantic City, N. J.

American Institute of Chemical Engineers will hold its summer meeting June 19-22 at Berlin, N. H.

American Institute of Electrical Engineers' annual convention June 26-28 at Atlantic City, N. J. Secretary F. L. Hutchinson, 29 W. 39th St., New York City.

Illinois and Wisconsin Retail Coal Dealers Association will hold its annual convention June 26 and 27, at Hotel Wisconsin, Milwaukee, Wis.

Illinois and Wisconsin Retail Coal Dealers Association will hold its annual convention June 26 and 27, at Milwaukee, Wis., with headquarters at Hotel Wisconsin. Secretary, Isaac L. Runyon, Chicago, Ill.

American Institute of Mining Engineers will hold its Colorado meeting Sept. 2-7. The tentative plan calls for one day at Denver, one day at Colorado Springs, one at Cripple Creek, an automobile trip to the top of Pike's Peak, one day at Pueblo and one day at Leadville. Secretary, Bradley Stoughton, 29 West 39th St., New York City.

Publications Received

Annual Report of the Mines. Department of Public Works and Mines, Province of Nova Scotia. Unillustrated, 79 pp., 6½ x 9½ inches.

The Storage of Bituminous Coal. By H. H. Stoek. University of Illinois Bulletin. Circular No. 6. Illustrated, 187 pp., 6 x 9 inches.

Bibliography of Petroleum and Allied Substances, 1915. By E. H. Burroughs. Department of the Interior, Bureau of Mines. Bulletin 149. Unillustrated, 123 pp., 6 x 9 inches.

Monthly Statement of Coal-Mine Fatalities in the United States, January, 1918. Compiled by Albert H. Fay. Department of the Interior, Bureau of Mines. Unillustrated, 21 pp., 6 x 9 in.

Monthly Statement of Coal Mine Fatalities in the United States, February, 1918. Compiled by Albert H. Fay. Department of the Interior, Bureau of Mines. Unillustrated, 19 pp., 6 x 9 inches.

Use of Permissible Explosives in the Coal Mines of Illinois. By James R. Fleming and John W. Koster. Bulletin 137. Department of the Interior, Bureau of Mines. Illustrated, 103 pp., 6 x 9 in.

Use of the Interferometer in Gas Analysis. By Frank M. Seibert and Walter C. Harpster. Department of the Interior, Bureau of Mines. Technical Paper 185. Illustrated, 16 pp., 6 x 9 inches.

Effects of Moisture on the Spontaneous Heating of Stored Coal. By S. H. Katz and H. C. Porter. Department of the Interior, Bureau of Mines. Technical Paper 172. Illustrated, 23 pp., 6 x 9 inches.

Manufacturing Opportunities in the State of Washington. By Harry F. Giles, Deputy Commissioner. State of Washington, Department of State, Bureau of Statistics and Immigration. Illustrated, 240 pp., 6 x 9 inches.

Safeguarding the Home Against Fire. Prepared for the United States Bureau of Education by the National Board of Fire Underwriters. Illustrated, 91 pp., 5 x 8 in. A fire-prevention manual for the school children of America.

Percentage of Extraction of Bituminous Coal with Special Reference to Illinois Conditions. By C. M. Young. University of Illinois, Bulletin No. 42. Engineering Experiment Station, University of Illinois, Urbana, Ill. Illustrated, 173 pp., 6 x 9 inches.

Oil-Storage Tanks and Reservoirs. With a brief discussion of losses of oil in storage and methods of prevention. By C. P. Bowie. Department of the Interior, Bureau of Mines. Bulletin 155, Petroleum Technology 41. Illustrated, 70 pp., 6 x 9 inches.

Trade Catalogs

Unless otherwise stated, a copy of the publications listed below may be obtained free by addressing the manufacturer.

Coxe Stokers. Combustion Engineering Corporation, New York. Bulletin Cl. Pp. 21; 6 x 9 in.; illustrated. Views and diagrams of typical Coxe stoker installations.

Class "FP" Steam Engines. Ingersoll-Rand Co., Easton, Penn. Form 883A. Single-page flyer on this engine, which is of the horizontal center crank type with piston valves.

"Little David" Evaporator Tube Cleaner. Ingersoll-Rand Co., Easton, Penn. Form 888. Pp. 4; 8½ x 11 in.; illustrated. Describes "Little David" evaporator tube cleaning and other labor-saving pneumatic tools.

Sullivan Duplex Air Compressors. Sullivan Machinery Co., Chicago, Ill. Circular 58-B (second edition). Pp. 24; 6 x 9 in.; illustrated. Instructions for installing and operating classes "WI" and "WJ" belt-driven air compressors.

"Ideal" Tilting Crucible Furnace. Ideal Furnace Co., Chester, Penn. Booklet. Pp. 16; 5 x 8 in.; illustrated. Gives description, test data and features of coal and coke furnaces for melting copper, brass, aluminum, bronze and other metals.

Centrifugal Boiler-Feed Pumps. De Laval Steam Turbine Co., Trenton, N. J. Bulletin N. Pp. 4; 8½ x 11 in.; illustrated. Describes the De Laval combined steam turbine and centrifugal boiler-feed pump. Electric motor-driven units are also described.

Safety First Motor Switch Condulets. Crouse-Hinds Co., Syracuse, N. Y. Bulletin No. 1000 H. Pp. 16; 8 x 10½ in.; illustrated. Describes what the company calls the "last word in small motor switches." The ZY condulets afford protection against shock, withstand rough usage, and cannot be operated by accident.

Lakewood Trackless Haulage Systems. Lakewood Engineering Co., Cleveland, Ohio. Bulletin No. 25. Pp. 24; 8½ x 11 in.; illustrated. Describes the trucks, trailers and tractors developed by the Lakewood company to meet the need for the economical handling of freight and machinery parts in large plants.

CR 3105 Drum-Type Controllers. General Electric Co., Schenectady, N. Y. Folder. Pp. 6; 8 x 10½ in.; illustrated. These controllers are recommended for use with direct-current adjustable speed motors driving machine tools. They are provided with armature and field control points and are supplied for reversing or non-reversing service.

Medart Steel Lockers. Fred Medart Manufacturing Co., St. Louis, Mo. Catalog A-5. Pp. 16; 7 x 10 in.; illustrated. Quite a pleasing example of the printer's art is this little catalog describing the steel lockers and locker-room equipment manufactured by the Medart company. The excellent halftone illustrations convey better than text the quality of the Medart products, though construction details and a price list for the standard sizes of lockers are given. Mine officials contemplating the purchase of locker room equipment should by all means procure a copy of this catalog.

Industrial News

Charleston, W. Va.—The Sunset Mining Co., whose plant is in the New River field, has changed hands, V. P. Veazy, of Mt. Hope, having disposed of his interests to Charles Ash, of Glen Jean, W. Va.

New York, N. Y.—There was shipped from the Port of New York during April 7107 tons of anthracite, valued at $49,785; 3081 tons of bituminous, valued at $21,304, and 633 tons of coke, valued at $16,757.

Morgantown, W. Va.—The National Fuel Co., of this place, has contracted with the Willis E. Holloway Co., Cleveland, Ohio, for a complete tipple for its new mine at Flaggy Meadow, W. Va. The operation will produce 2000 tons daily.

Barbourville, Ky.—The Trace Branch Coal Co., which recently filed notice of an increase in its capital to $15,000, is now developing about 40 acres of property having a capacity of about 20 tons daily. R. Bassett Minton is president.

Cleveland, Ohio—The Willis E. Holloway Co., consulting and contracting engineers, have been awarded contract for complete steel tipple for the No. 3 mine of the Elm Grove Mining Co. at Triadelphia, W. Va. The tipple is to have a capacity of 2500 tons a day.

Whitesburg, Ky.—The coal operators of Letcher County, Kentucky, met at the Whitesburg Hotel on June 4 and organized themselves into the Letcher County Coal Operators' Association. J. Henry Hall, of the Whitesburg Coal Co., was chosen president and John F. Maurice, of the Ulvah Coal Co., secretary and treasurer.

Charleston, W. Va.—One thousand nine hundred and forty-nine injuries were reported and 1772 applications for compensation were received in the month of May by the State Workmen's Compensation Department. Sixty-one of the injuries proved fatal. Of the injuries reported 876 nonfatal and 50 fatal occurred in coal mines. One thousand five hundred and five claims were awarded.

Sussex, N. J.—The Lehigh & New England Railroad Co. has awarded a contract to Fairbanks, Morse & Co., 30 Church St., New York, for the construction of a large concrete coaling station in the lower section of its local yards. The new plant is estimated to cost in the neighborhood of $40,000, and coaling machinery of the latest type will be installed immediately upon completion of the construction work.

Birmingham, Ala.—At a recent meeting of the Alabama Coal Operators' Association the following officials were reëlected for the ensuing year: President, George B. McCormick, Pratt Consolidated Coal Co.; vice president, Charles F. DeBardeleben, Alabama Fuel and Iron Co.; secretary and treasurer, James L. Davidson. Executive committee: George G. Crawford, J. B. McClary, Walter Moore, A. H. Woodward and George F. Peters.

Birmingham, Ala.—The Railway Fuel Co. has increased its capital stock from $10,000 to $200,000. This company, which is officered by officials of the Southern Ry., is developing coal properties in Walker County, where work has been under way for several months, the mine being opened up to be equipped with modern tipple and washery facilities. The output from this operation will be used exclusively in the operations of the Southern Ry. system.

Louisville, Ky.—With approval of Wiley B. Bryan, Kentucky fuel administrator, the Jefferson County fuel administration has issued a new regulation under which a charge of 30c. a mile from yard to destination will be made for coal delivered by local retailers to consumers outside of the city limits. It was held that the 75c.-a-ton delivery allowance was unfair on long hauls and had resulted in city dealers, in many cases, refusing to accept orders.

Grafton, W. Va.—At the second annual meeting of the Grafton Coal Operators' Association, held here on Thursday, June 6, the following officers were elected: President, George S. Brackett, of Flemington, general superintendent of the Pitts-Vein Coal Co.; vice president, Thomas Murphy, of Austen, general superintendent of the Gorman Coal and Coke Co.; secretary and treasurer, W. J. Carnahan, general superintendent of the Deaker-Hill Coal Company.

St. Louis, Mo.—August A. Busch, president of the Anheuser-Busch Brewing Association, who is the principal owner of Nigger Hollow Mines No. 1 and 2 near French Village, Ill., operated by the St. Louis & O'Fallon Coal Co., in a statement given to newspapers asserting the loyalty of the Busch interests to the Government, says that the output of the mines, the capacity of which is more than a million tons a year, has always been sold at a price considerably below that fixed by the Government.

Toledo, Ohio—Activity in the lake trade still prevails at the Toledo docks of the various coal-carrying roads. During the week ended June 7 the Toledo & Ohio Central docks handled 71,000 tons as compared with 68,000 tons the previous week. The total handled since the opening of the season is 405,000 tons. The Hocking Valley docks during the week ended June 8 loaded 11,744 tons as compared with 126,841 tons the previous week, making a total of 731,580 tons since the opening of the season.

Buffalo, N. Y.—Members of the grain trade here have organized the Cadiz Coal and Lumber Co., with $300,000 capital stock. They have 700 acres of coal land near Cadiz, Ohio, which will produce an estimated 3,000,000 tons of No. 8 coal and which is covered with 3,000,000 feet of hardwood timber. The Government has given them an order for the lumber. The incorporators are H. A. Smith, C. J. Meyers and M. C. Burns, of Buffalo. Operations will begin soon. The coal is tributary to the Cleveland market naturally.

Columbus, Ohio—H. S. Riddle, of the Ohio Board of Administration, is again figuring on the proposition for the State of Ohio to own its own coal mines. The Ohio Board of Administration has charge of 22 state institutions and uses about a half million tons of coal yearly. Mr. Riddle reports that several attractive propositions have been made to the board recently by owners of coal lands in the Hocking Valley. Pending decision in the matter the board has taken no action toward buying its coal supply for next winter.

Indianapolis, Ind.—The new Indianapolis board of health expects to build at the city hospital a large concrete coal bin for the storage of coal for the winter. The bin will have a capacity of 1000 tons and the coal will be maintained under water so as to prevent combustion. This amount of coal will run the hospital only 60 days, but it is the expectation to use this supply only as a reserve to tide over a possible fuel shortage next winter. Last winter, on two or three occasions, it was feared that the hospital would have to close on account of being entirely out of coal.

New York, N. Y.—Preparations are under way whereby shipments of coal from Rochester (and possibly another point) to New York will soon be made on the New York Barge Canal. G. A. Tomlinson, general manager of the New York Canal Section of the Railroad Administration, made an inspection of the canal last week and has his plans under way. It is pointed out that by shipping coal to Rochester from the mines and dumping it into barges for shipment through the canal, a car can make four trips between the mines and the canal docks while it is making one trip from the mines to tidewater.

Moundsville, W. Va.—By utilizing 15 big trucks to haul coal from its Marshall County mines to the Riverside and La Belle mills, and from its Belmont County mines to the La Belle mills, L. L. Salomon, local manager of the Philadelphia & Cleveland Coal Co., estimates that one truck in a single day releases 20 coal-car days, or in other words, does the work of one coal car that it would take 20 days to do and that, therefore, 15 trucks means the release of 200 coal-car days every day they work. It is also estimated by Mr. Salomon that a week's haul by the company's trucks represents 4860 tons of coal hauled.

Columbus, Ohio—Rate increases in Ohio on coal shipments after June 25 will be increased in accordance with the announcement of Director General of Railroads McAdoo. The present rate from the Hocking Valley to Columbus is 80c. and the new rate will be $1. From the Hocking Valley to Toledo, Lima, Dayton and western and northern Ohio points the old rate was $1.15 and the new rate will be $1.45. From the Hocking Valley to Marion the old rate was $1 and the new rate will be $1.30. The rates from the Jackson field to all points, except Lima, will be the same as from the Hocking Valley. From the Pomeroy field the same rates prevail.

Columbus, Ohio—While in Washington last week to secure from the Railroad Administration some relief in the matter of car supply for Ohio wagon mines, James B. Dugan, of the Ohio Public Utilities Commission, was informed that so far from any more open-top cars being given to these small mines, the supply may be curtailed, as an order is contemplated by the Administration, postponing the requirements of such mines to those of mines with tipples. If this is done, Mr. Dugan declares that the wagon mines, whose production forms an important item to consumers in a considerable territory in central Ohio, will be put out of business completely, as the car supply is recognized as being inadequate to give all tipple mines a full supply.

Pittsburgh, Penn.—The Dravo Contracting Co. has announced it will operate its Neville Island plant as a separate department, to be known as The Dravo Contracting Co., Engineering Works Department. It has been manufacturing whirlers, steel towboats and barges for some time, and due to increased business has found it advisable to make this change. The concern has contracts for 33 towboats and barges, the majority of which are for use by the United States Government. In addition to this, it has a large number of orders for tower whirlers for handling material at shipyards. An entirely separate purchasing, accounting and engineering organization has been installed. J. D. Berg has been made vice president of the Dravo Contracting Co., in charge of the Engineering Works Department.

Springfield, Ill.—W. C. Hurst, vice-president and general manager of the Chicago, Peoria & St. Louis Railroad Co., has written to the mayor and commercial organization of every town on the line offering storage space for coal along the right-of-way to all who may need it. His motive, he says, is not only to help the Fuel Administration but to make business for his road at a time when coal can be hauled to the best advantage. His engines, he explains, can haul full loads of coal now, whereas in cold weather they can pull only one-half to three-quarters of a load. Besides, freight traffic is not so heavy now as it will be later, and his road has a maximum equipment available for coal transportation. He insists that the deterioration will be slight. The company has already, he says, begun to store coal for its own needs next winter. Responses are being received from the towns and he thinks that his campaign will have substantial results.

St. Louis, Mo.—J. D. A. Morrow, in charge of distribution for the Federal Fuel Administration, was the guest of the Fifth and Ninth Districts Operators' Association and the Missouri Retail Coal Dealers' Association at the Jefferson Hotel Tuesday evening, June 4, during a stopover on his way to Kansas City, and delivered an address in which he told them why St. Louis cannot have any anthracite this year and forecasted a coal shortage next winter. He explained that this was practically inevitable because even if the mines produced sufficient coal and the railroads were able to transport it, the movement would have to be consistent with the movement of other materials needed for the production of war essentials. In answer to a question he cleared up the uncertainty that has surrounded the railroad coal situation. The order that the railroads were to pay the same as other consumers meant, he said, that producers could ask the maximum Government price but could also sell at less than the maximum if they chose. He said the railroads would be required to distribute cars equally to all mines and that contracts for coal made by railroads since Dec. 29 were automatically abrogated. He explained that St. Louis could not have any anthracite because the difficulties of transportation necessitated giving it to the munitions-manufacturing districts of the East. In answer to a question of E. D. Nims, Chairman of the St. Louis Fuel Committee, he said that the railroads would be required to store for next winter to their full capacity and said that but for the dispute about what the railroads were to pay, which had caused the loss of three months time, millions of tons would now be in storage.

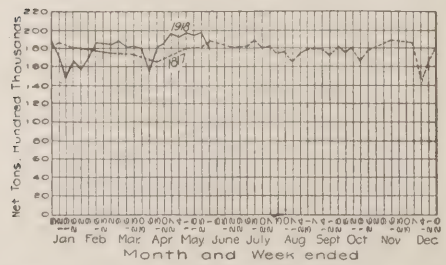
Weekly Review

Slump in Both Anthracite and Bituminous—Question of Adequate Labor Supply Disturbs Hard-Coal Operators—Production Bureau to Stimulate Coal Output—Need of Conservation—Automobile Industry Receives Drastic Cut in Fuel Allotment

THE decrease in production of bituminous coal during the week ended June 1, owing to the observance of Memorial Day in the mines of the northern states, seems to accentuate the fact that only by full-time operation will the mines be enabled to furnish the minimum of 634,000,000 net tons of soft coal necessary to keep war industries going and warm the homes during the coming year. To secure this output it would be necessary to maintain an average weekly production of more than 12,000,000 net tons. This tonnage has not been produced in any single week during the history of the bituminous coal mining industry. In the week ended June 1 the output fell considerably more than one million tons below this average, only 10,774,000 net tons being mined.



Anthracite production, too, suffered a decrease during the week ended June 1. Both the laying-off for the holiday and an inadequate labor supply contributed to keep hard-coal shipments down to 31,762 cars, a decrease of 8832 cars when compared to the anthracite shipments the preceding week. The labor question seems to be the main disturbing factor to maximum hard-coal production at the present time, and it is one that should receive the immediate attention of interested officials. Not only has the anthracite industry lost more than 32,000 men since we entered the war, but the draft is continually making further inroads. It is hard to see how the necessary quantity of anthracite can be produced with the labor force that is now available. By eliminating skilled miners from the draft, and suspending for the duration of the war the Gallagher bill (which prohibits the employment of miners underground unless they have had two years' experience in the mines of Pennsylvania), the situation would be helped materially.

It is evident, therefore, that two things are essential to a solution of the coal problem—intensive production and the strictest kind of conservation. The former has already received the recognition of the Federal Fuel Administration by the formation of a "production bureau," headed by James B. Neale, who has been acting as advisor to Mr. Garfield. It will be the duty of this bureau to do everything possible toward increasing the volume of anthracite and bituminous coal mined. The matter of conservation rests in large measure with the consumer, who must at all times exercise the greatest watchfulness in the manner in which he burns his coal. Industries not engaged in war work will have the utmost difficulty in obtaining coal in the future, the automobile manufacturers being the latest to have their fuel supply curtailed. By an order of the Fuel Administration the allotment of coal to this industry has been cut down to 25 per cent. of its 1917-1918 requirements.

So far as trade conditions are concerned, dealers are making deliveries as fast as they can and generally are bare of stocks. Demand for all grades of coal is greater than the supply. Lake shipments so far have been below expectations, though carrying capacity is plentiful.

COAL PRODUCTION

The observance of Memorial Day at the mines in the northern states caused production of bituminous coal during the week of June 1 to decrease 1,025,000 net tons, or 8.7 per cent. The output of soft coal (including lignite and coal made into coke) is estimated at 10,774,000 net tons as compared with 11,779,000 net tons during the week of May 25. The average per working day for the week ended June 1 is estimated at 1,796,000 net tons as against 1,966,000 during the preceding week and an average daily production during May, 1918, of 1,918,519 net tons. Although Memorial Day

was not universally observed, the curve showing production per working day has been based on 6 days in the week.

Preliminary estimates place production of beehive coke during the week ended June 1 at 612,000 net tons, a decrease of 51,000 net tons, or 7.7 per cent. compared with the week of May 25. The average daily production amounted to 102,000 net tons as against 111,000 net tons during the week preceding.

Beehive Coke—Beehive coke production in the Connellsville and adjacent regions declined slightly during the week ended June 1. The principal operators located in the Connellsville, Greensburg and Latrobe districts report production of 308,735 net tons, or 76.2 per cent. of their present rated capacity as against 77 per cent. during the week preceding. Out of total losses of 23.8 per cent., 19.4 per cent. was attributed to insufficient yard labor against 15.4 per cent. during the week of May 25 and 4.4 per cent. to all other causes as compared with 7.2 per cent. The same operators produced 140,100 net tons of coal operating at 44.6 per cent. of their present rated capacity.

Byproduct Coke—The production of byproduct coke during week ended June 1 again declined slightly and is reported at 87.7 per cent. of maximum capacity as compared with 88.5 per cent. during the week preceding.

Of the factors limiting production shortage of coal losses increased during the week from 2.6 per cent. to 2.8 per cent., labor shortage losses from 2.6 per cent. to 3 per cent., repairs to plants caused losses of 5.4 per cent. as against 4.9 per cent. and "no market" losses rose from 0.2 per cent. to 0.3 per cent. Losses attributed to all other causes declined from 1.2 per cent. to 0.8 per cent.

Material decreases in production for the week of June 1 are reported by Alabama, Minnesota, Pennsylvania, Tennessee and West Virginia. In Alabama and West Virginia the decrease in production is attributed to repairs to plants, in Minnesota to "no market" and other causes, in Pennsylvania to insufficient labor and in Tennessee to lack of byproduct coke.

Kentucky and Maryland are the only states reporting material increases, the former state attributing the improvement to repaired plants and the latter state to better labor conditions.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended May 11	May 18	May 25	June 1
Bituminous shipments, 123 roads.	207,145	205,026	207,036*	188,864†
Anthracite shipments, 9 roads...	38,767	41,011	40,594*	31,762†

* Revised from last report. † Subject to revision.

Anthracite shipments during the week ended June 1 decreased 8832 cars, or 22 per cent.

BUSINESS OPINIONS

Marshall Field & Co.—The wholesale distribution of dry goods for the current week is very much ahead of that of the corresponding week in 1917. Road sales for both immediate and future delivery show a slight increase over those of the same period a year ago. Customers have been in the market in greater numbers than during the corresponding week last year. Collections are very good, being even larger than they were for the same week a year ago. The prices of domestic cottons are firm.

American Wool and Cotton Reporter—There is no definite prospect of any shortage of wool now, but on the other hand there is no bright outlook for civilian fabrics which require certain wools. The stand which the War Industries Board has taken should be enough to indicate that the supply of woolen cloth will not be overlarge for some time to come, and that conservation is much more necessary than it has been previously. The consumer will not feel any effect of the shortage for a long time, if anything like a reasonable policy be adopted.

Bradstreet's—Government domination of a myriad of lines of industry and trade and almost unanimously favorable crop reports are the two great outstanding features of the situation. Government commandeering of the iron and steel, wool and heavy leather outputs are accomplished facts, and further extension of its control of manufactured textiles and of food supplies and prices of same seem inevitable.

Great basic changes are therefore proceeding under the new and fast-moving monopolization of human activities, directly or indirectly, in the war. Man power is being taken up steadily and rapidly by the second draft, and the attraction of female labor into lines formerly monopolized by men is growing apace.

Dry Goods Economist—The most important development of the week is the prospect of relief to the raw-cotton price situation afforded by the Government report as to the condition of the growing plants. This is placed at 82.3 per cent., against 69.5 on May 25, 1917, and an average of 79 for the last ten years. The Government has not yet published its estimate of acreage, but there is every reason to believe that it will be unusually great. The only offset to this is the large number of negroes—nearly 30,000—who have been summoned to the colors from the cotton states and must respond during June, many of whom doubtless would otherwise be available for work in connection with the raising and gathering of cotton.

The Iron Age—In an order dated June 6, which no one in the steel trade fully understands, the War Industries Board has put in the hands of J. L. Replogle, Director of Steel Supply, the distribution of the entire iron and steel output of the country. Starting with the sweeping provision that no pig iron or steel products shall be shipped except under priority certificates, the order provides that after all priority requisitions have been filled producers may supply their customers if the latter are on a preferred list, which, as revised, is to be sent out later. Steel ingot production in May, unlike that of pig iron, shows a slight falling off from the April rate. In 27 working days, May 30 not being a steel works holiday, the output of companies which made 88 per cent. of the country's total in 1916 was 3,256,965 gross tons, or 120,628 tons a day, against 3,163,410 tons in April, or 121,670 tons a day. The May rate, estimating companies not reporting, would mean about 42,300,000 tons a year.

Atlantic Seaboard

BOSTON

New distribution plan announced. Elaborate system of checks devised. Receipts continue short. Trade much interested in probable effect on shipments. Losses during May due to various causes. Not enough emphasis upon "balanced production." Difficulty of policing any plan for distribution. Railroad fuel difficulties not yet solved. New England railroads feel the pinch on supply. Hampton Roads dumpings sag. Submarine menace causes slow movement. "Zoning" of smokeless coals a misnomer. Fuel authorities prepare the most rigid supervision yet of cargo disposition. Only coal to preferred requirements moving all-rail via Shippensburg. Continued alarm on the part of New England buyers. Renewed buying of anthracite steam sizes. Directions issued to favor New England destinations all-rail on domestic sizes. Water coal slows up materially. Continued comment on "allotment," but actual shipments decrease.

Bituminous—The news most interesting to the trade this week concerned the program for distribution recently given out by the Fuel Administration. The burden of deciding upon the disposition of what coal comes forward to any state is now shifted from district representatives to state administrators, following out the theory that those on the ground are better qualified to exercise this function. The order of preference designated by the War Industries Board is to be followed strictly. Railroad requirements and those of the Army and Navy and other departments of the Federal Government are to be cared for from Washington, at least in theory; all other needs, except in certain special cases, are to be met by state administrators. Jobbers are to be allowed to have coal running in their names, subject, however, to supervision by the state administrator who has jurisdiction over the port of discharge.

Meanwhile, bituminous receipts continue to show a marked falling off. The number of cars passing the gateways the first six days of June showed a total of commercial coal amounting only to 446 cars daily, a drop of 24 cars from the May average, which was the lowest for the year thus far. Railroad fuel, however, showed a slight gain, 121 cars daily having been received against the May average of 98.

There are many reasons advanced for the serious shortage in the volume of bituminous all-rail. It has been represented to be largely due to the large demand for bunker fuel at New York and at Philadelphia, but this alone would not have been sufficient. Neither is there any ground for talk of railroad congestion when much of the coal was diverted to the most congested area in the country, about Philadelphia, and the New England roads were not only clamoring for coal to haul but complained bitterly over their small receipts for supply purposes. The great obstacle from a New England standpoint was the Preference No. 1 list and the drastic way in which the Washington instructions were interpreted by the district representatives. This territory has a large number of preferred requirements, although in volume of coal used the needs are relatively small. Enormous industries in Pennsylvania were obviously entitled to preference, and it took no great effort on the part of anybody to get them on the list. Many important New England plants, however, are among the 10,000 or more who are represented in applications to the War Industries Board which have not yet been acted upon. It should be said that at the present rate of progress it will be several years before they are acted upon, and should this plan have been followed implicitly there would have been real disaster to many important industries and untold delays caused to the war program.

On other accounts the previous program had to be abandoned. Steel and rolling mills would have been favored with coal when the small plant in New England would have had to go without, although its output was just as necessary for war purposes, in many cases furnishing a part that was indispensable. Not enough emphasis has been placed upon "balanced production," and merely because coal requirements are relatively small is no reason for passing them over. In tons of material the output of Pennsylvania, for instance, is much larger, but in the number of men employed per ton of coal New England doubtless makes a better showing. This territory is working from 65 to 75 per cent. on war orders, and it is a keen realization of the necessity that work be kept going that so many officials high in the Government are trying to see to it that New England gets its share.

The submarine threatenings have a marked effect upon the movement of coal coastwise. For days at a time the ports have been closed, and there is talk of systematic convoy for all coal carriers. Such a practice would slow up deliveries and the efficiency of units now in use would be much impaired. The effect upon the volume of coal dumped at Hampton Roads, and indeed upon coal sent to the piers, is already considerable. No sooner did a few bottoms appear at the terminals than the tonnage of coal in transit at once fell off and opportunity was taken to supply Virginia hospitals and other local necessities on the line of the principal railroads and on connecting roads as well. Thereby a further possible increment to New England's budget was lost.

It develops that byproduct plants must now have certain arrears in tonnage made up, and by direction of the Fuel Administration several shippers are obliged to make allotments from tonnage that would ordinarily be sent to the piers for export and for New England. It further appears that while great efforts were made to "zone" Pocahontas coal east, away from the Western market, the 35c. price differential made the Western trade peculiarly susceptible, and through "permits" the actual tonnage of Pocahontas moving west is on a basis fully as large as last year. In that respect, therefore, the zoning plan was a misnomer.

While there is no operating embargo against shipments in open-top cars all-rail to New England via Shippensburg from the Baltimore & Ohio and the Western Maryland, there is in effect an order of the Fuel Administration that effectually prevents any but deliveries in box-cars and to preferred requirements. This only adds to the alarm of most buyers, who see little chance of relief in any direction. Manifestly, stocks were greater than supposed, or several large plants would have been shut down by June 10. The new distribution plan will give some encouragement, for it will be felt that a local fuel administrator will be much more competent to deal with real emergencies than an official 500 miles or more away. Renewed buying of anthracite steam sizes is also notable, a decided impetus having been given this trade within a few days. There is more discrimination between grades than was the case last winter, and many coals of demonstrated value suffer somewhat in finding a market through the wholesale abuses last winter of the term "screenings."

The trade is certainly relieved to find that the drastic method of distribution through district representatives is being supplanted by a better considered program. The idea that preferred consumers were to be "taken care of" before deliveries were to be allowed to come forward to any others was hopeless for the community at large.

Anthracite—For the first six days of June the average daily movement of domestic sizes all-rail was only 420 cars, a loss of 34 cars each day from the May average. Of this movement 26.6 per cent. was steam sizes, or a daily average of 152 cars This also was below the May average.

Due to the submarine activity the anthracite shippers had instructions a week ago to increase deliveries all-rail to such New England points as ordinarily are served by water. It will be interesting to see to what extent the movement can thereby be increased.

There are few developments in the anthracite trade as a whole. Receipts by water have sagged to a remarkable degree, and there is increasing confusion over instructions from Washington as to distribution. Retail distributors are now disturbed over a new regulation requiring apartment houses to be furnished with bituminous rather than anthracite, although hitherto preferences for anthracite were regarded.

NEW YORK

Dumpings of anthracite at the local tidewater docks show slight decrease from previous week, while bituminous dumpings show large increase. Dealers and consumers anxious for coal. Producers look for action regarding mine workers going to war. Bituminous situation little changed. Demand continues strong.

Anthracite—The effect of the order of the Anthracite Committee of the Fuel Administration that, on account of the interruption to water shipments to points east of Boston, as large a tonnage as possible be shipped to points in New England west of and including Boston, and also that liberal shipments be made into the various New England States all-rail, has not, so far, been felt to any extent here. Dumpings at the various local docks for the week ended June 10 totalled 6522 cars, or 20 cars less than were dumped the previous week.

Dealers and consumers here are anxious as to receiving sufficient supplies to meet their needs. Receipts locally do not appear to have increased to any extent, and consumers are strong in their demands for coal. These demands are strongest in Brooklyn, where a majority of the consumers live in individual houses. A telegram received by the Brooklyn "Daily Eagle" from Dr. Garfield said that the Fuel Administrator expected coal production and distribution sufficient to prevent any domestic suffering or curtailment of essential industries, provided only that the public coöperate with the Administration in stopping thoughtless waste and using coal efficiently in summer as well as in winter.

However, there is much uneasiness among the trade and public because of the lack of deliveries, and this urgency is becoming more apparent as the time draws near for many persons to close up their homes for the summer.

Similar conditions exist throughout Long Island, most of which is supplied with coal from the New York tidewater. Fuel Administrator Hawkins, of Suffolk County, has announced that he has asked for and needs 200,040 tons of coal this year, an increase over the consumption of 1916 and 1917.

Early this week there were reports that a state fuel administrator was to be appointed shortly to succeed Albert H. Wiggin, who resigned several weeks ago. The appointment of Mr. Wiggin's successor has been urged by the trade, who believe that the position should be filled now.

Producers here believe that the time has now come when the authorities should take some action to prevent a further depletion of the working forces in the mines, if it is desired to keep production up to the present mark. It is intended to ask that all mine workers be placed in Class 5 of the draft call, otherwise it is pointed out it will be impossible to get out the coal necessary to meet the country's needs.

The order of William Potter, state fuel administrator of Pennsylvania, discontinuing shipments of anthracite to 29 counties of that commonwealth, is not expected to add anything to the tonnage allotted to this state.

Announcement has been made that plans have been nearly perfected whereby the city authorities will be able to obtain a reserve stock of coal with which to take care of the fuel needs of the poor next winter. All of the domestic coals, including pea, are scarce both for tidewater and line delivery. The trade is willing to take

whatever it can get in the way of tonnage. There is a good demand for the buckwheat coals. The larger of these is short. Rice is easier while barley moves freely. Prices on all are held firm.

Current quotations, per gross ton, f.o.b., tidewater, at the lower ports are as follows:

	Circular	Individual
Broken	$6.55	$7.30
Egg	6.05	6.80
Stove	6.30	7.05
Chestnut	6.40	7.15
Pea	4.90	5.65
Buck	4.45@5.15	4.80@5.50
Rice	3.90@4.10	3.80@4.50
Barley	3.40@3.65	3.00@4.00
Boiler	3.65@3.90	.....

Bituminous—The local situation shows no big improvement, either in supplies or in lessening of demand. While the dumpings at the local tidewater docks for the week ended June 10 show a total of 7569 cars as compared with 6393 cars for the previous week, an increase of 1176 cars, it does not indicate that the local trade received any more coal, as the demand from New England and nearby water points have increased considerably because of the interruption in shipments from the Southern ports.

Locally, commercial coals are scarce. Efforts of shippers to pick up a stray cargo or two have been failures. Bunker fuel is easy and shipping has not been delayed to any extent.

PHILADELPHIA

Anthracite retailers' receipts continue light. Resume agitation against basic year plan. New England preferential continued. Planning division of increased allotment. City wants 25 per cent. increase. Local zoning plan again considered. New ruling on consumers' orders. Buckwheat exemptions being felt. Bituminous supply continues in fair volume. Car supply good. Submarine activity discounted in tide shipments.

Anthracite—It has been another discouraging week from the retailers' standpoint which has made them more pessimistic than ever. Those who have suffered the most and received the least coal are those who in March, 1916, prudently filled their yards to capacity in order to care for their trade that spring, in the event of expected troubles in the mining region. As their receipts for the months of April and May that year were necessarily light, it is becoming more apparent that these buyers are now paying a penalty for their forethought. This year no dealer was furnished with more coal in April and May, more particularly by the big companies, than was purchased during the same period of 1916.

For June the sales agents are advising their customers quite frankly that owing to the heavy consignments to New England it is possible their quota will not be filled. In fact we have complaints from some, including the largest firms in the city, that their May proportion did not reach them. This is in strong contrast to what was expected, for in April a number received a little surplus and it was felt that this would be the case right through the season. However, the New England preferential instructions have been continued in force and it now looks as if this would be the case right into fall. It is known that at this very time the shipments to the Port Richmond piers are particularly heavy, and at times it looked as if a congestion might result, which is the only chance of the local dealer getting a little extra coal.

Until late in the week no definite policy had been announced as to the distribution of the excess tonnage of 18.25 per cent. over the 1916-17 tonnage as allotted to this state. It would appear that the state and city fuel authorities are not in entire accord with the Federal Distribution Committee as to its distribution.

Some of the largest retail buyers are disappointed because as yet no official announcement has been made that this city will receive 25 per cent. of the additional tonnage. There seem to be assurances emanating from the local distributors' offices that such a statement would be given out ere this.

The distribution committee is doing its utmost to meet the increased demand from this city, as is witnessed by their latest order in cutting off anthracite from 29 counties in the state, which are located in the heart of the bituminous district. The community most affected by this move is Pittsburgh in Allegheny County, as local operators have shipped quite a tonnage of anthracite to that city for years.

The German submarine activities for a while had a considerable effect on tide shipments here, to the extent that an increased shipment via all-rail had been ordered, which means more cars with the subsequent delays in returning the empties to the mines. It is not thought this will continue for any length of time, as it is felt that the present warlike activities off the coast will soon subside.

This week Chairman Lewis, of the city fuel administration, issued an order that is causing considerable comment. He calls the dealers' attention to the fact that as their allotment for the present coal year is based on their requirements he refuses to allow any further shifting of the orders of the consumers. In other words, where an order has been placed with one dealer it must not be cancelled and filled with another.

The state fuel administrator has made a cheering announcement to the retailers. Mr. Potter stated that the supply of anthracite domestic sizes of coal needed by essential industrial plants would be held back as long as possible to give householders the opportunity to lay in a reasonable stock. The only exception will be to plants working on war materials, and these must obtain the indorsement of the department of the Government for which they are working. In the same connection Mr. Potter again calls attention of all citizens to the need of the strictest economy in the burning of coal. It is understood that churches are to be allowed but two-thirds of their normal supply, and that other steps are about to be taken to insure more coal for domestic use.

The buckwheat exemption which the steam plants were required to procure from Washington is making its impress heavily felt in the steam trade. On applying for this exemption certain plants have been advised that it cannot be allowed and they must adapt their boilers to smaller sizes of coal. The great difficulty in this latter case is that the consumers do not know where to get the smaller sizes of fuel, as practically every company is sold up on these sizes

The prices per gross ton f.o.b., cars for line shipments and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4 90	$6.05	Buckwheat	$3.15	$3.75
Egg	4.50	5 70	Rice	2 65	3.65
Stove	4.75	6.05	Boiler	2 45	3.55
Nut	4.85	6.10	Barley	2.15	2.40
Pea	3.45	4.35			

Bituminous—A good supply of coal continues to come in and the important plants are storing away quite a considerable tonnage. There continues, of course, to be much pressure on all sides for increased shipments, but it can be said that conditions are closely approaching the point of being satisfactory. While some shippers do not report the car supply as being as favorable as last week, yet there are others who report an improvement.

Operators were hardly more than just interested in the ruling cutting off anthracite shipments to soft-coal producing counties. They state that there would be no particular trouble in taking care of this increased local domestic business, and as a matter of fact took the stand that it belonged to them and expressed the wish that in normal times it would stay with them.

For a while this week during the submarine attacks off the coast nearby there was some tendency toward congestion of bunker fuel at the piers, but this has now practically been eliminated and vessel movement is now going on about as usual.

An interesting case was heard of this week where a big power plant had adopted the plan of screening all its bituminous ashes and burning the screenings. It is claimed that the results are most satisfactory, a carbon content of as much as 15 to 20 per cent. being obtained from the ashes.

BALTIMORE

Bituminous receipts here comparatively heavy, but there is much complaint against poor quality fuel. Anthracite dealers have troubles and also ask that freight-rate increase be suspended for coal.

Bituminous—Considerable soft coal for all purposes is arriving here, but all of it is not desirable coal by any means. Many rejections have been made recently from the pool on coal consigned to the Maryland fuel administrator. The officials here say that they are determined to have only good coal shipped into this zone. Probably Baltimore felt the condition worse than other points, as among the considerable amount of coal diverted here at the Cumberland gateway because of railroad congestion, improper marking or attempts to consign out of specified zones, was some that did not appear to come up to requirements and which was redestined here for further inspection. This coal in large quantity was thrown out of the pool and had to be cared for by the jobbing trade. Because of the fair amount of good coal to be had here at Government prices, it was not always easy to dispose of the less desirable kind at the same prices. The jobbers are still working for a reclassification, and many of those here expect to forward cost sheets to Washington shortly in the move for a revision higher of their profit margins.

Anthracite—The hard-coal men here are having many troubles. Receipts for April were below average on even a three-quarter supply basis, May was worse, and in June so far only one big shipper has held anything like up to average. The result is that while a few dealers have been able to handle a fair proportion of coal, many others have had so little fuel to distribute that their forces and equipment were practically idle on some days. A meeting was held with the city fuel committee of the state fuel administrator and predictions were made that unless some new plan of relief and more equitable distribution is established by the Government shortly that a number of dealers will have their efficiency as distributing agents seriously curtailed. Among other things a protest was sent to Washington against any move to increase the freight rates on coal before Sept. 1. A jump of 50c. additional a ton at this time, the retailers say, when the business is already under heavy stress, would be a mistake. The representative of the United States Coal Merchants' Association at Washington has been asked to present this view to the Fuel Administration and Director of Railroads McAdoo.

Lake Markets

PITTSBURGH

Better car supplies uncover more labor shortage. Market sales somewhat heavier. Not enough stocking.

There has been a slight improvement in coal production in the district. Car supplies are unsatisfactory in many instances, but on the whole are much better than a fortnight ago. The increased car supplies have uncovered more of a labor shortage, and the percentage of lost production ascribed to car shortage is decreasing while the percentage ascribed to labor shortage is increasing. This does not mean that the supply of labor has actually decreased, though if the condition were considered without thought, and particularly the figures shown in the weekly report of the Geological Survey, such an inference might be made. The aspect at the coal mine is that to determine the day's operations the cars for loading must be in sight, and the operator counts the cars that are waiting to be loaded rather than the men that are waiting to see what the day's operations are to be. If there were no cars at all, there would be no labor shortage disclosed, but if there is a 100 per cent. car supply, a shortage of labor is almost certain to be uncovered.

Lake shipments are proceeding with a considerable degree of smoothness. Calculations have been somewhat disturbed, however, by a prospect that the shipping season, with respect to coal, is to be shut off by formal decree about Oct. 1, instead of running to the end of lake navigation, and doubts are entertained whether sufficient coal can be moved by Oct. 1.

Sales of coal in the open market are somewhat more frequent, and a fair amount of this business is being handled by brokers who are still able to collect the commission from many customers. There is a moderate amount of stocking by large consumers, particularly byproduct coke producers, but not nearly so much as is considered necessary to avoid a shortage next winter when, at the best, transportation will not be so good as in the summer. The market remains quotable as follows: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, subject to 15c. brokerage allowed to be charged by brokers to customers.

TORONTO

Heavy demand for anthracite. Consumers anxious to stock up for winter. Dealers overwhelmed with orders. Increased prices anticipated.

Conditions in the coal trade show little change. The receipts of anthracite are quite inadequate to meet the heavy demand of consumers anxious to lay in their winter stock. Dealers are busy endeavoring to overtake orders in arrears, and some of them are refusing to accept new orders. The public appears to have become thoroughly aroused to the need of stocking up early in the season. Bituminous is in heavy demand with fair supplies. Prices

remain unchanged for the present, but an advance is anticipated shortly.

Quotations for best grades per short ton are as follows: Retail anthracite, egg, stove, nut and grate, $10; pea, $9, bituminous steam, $8.50; slack, $7.50; domestic lump, $10; cannel, $13; wholesale, f.o.b. cars at destination, three-quarter lump, unprepared, $6.11; prepared, $6.31; slack, $5.18.

BUFFALO

Jobbers get promises, not much else yet. Fair demand for bituminous. Anthracite running down. Car supply good.

Bituminous—Jobbers differ somewhat as to the demand. Many of them are doing a small business, both here and in Canada, but the consumer seems to be pretty well satisfied with the supply. In spite of the continued report that a shortage will appear at the end of the season, stocking is not very general, nor does it appear that conservation is being practiced.

The jobbers are taking heart, especially since the predictions and promises made at the convention, but actual business has not increased visibly of late. Still the feeling is better than it was. The efforts of the Fuel Administration to make a short supply go as far as possible and meet the greatest needs are becoming better understood. If the car supply continues good the trade may be able to distribute coal more freely and possibly get something out of it.

Prices appear to be entirely on Government basis here, in spite of reports of bonuses paid elsewhere. For Buffalo, by new schedule, they are $4.65 for thin-vein Allegheny Valley, all sizes; $4.45 for Pittsburgh lump; $4.20 for Pittsburgh mine-run and $3.95 for Pittsburgh slack, f.o.b. Buffalo.

Anthracite—The supply is not so liberal as it was, especially to the local trade. Much effort is made to keep up the lake shipments, though all the shipping agents are complaining. They can get lake tonnage enough, but vessels will not wait long, as the demand for ore carriers is active.

Reports are coming in from Canada that consumers of anthracite are buying bituminous now, sometimes up to 50 per cent. of their winter needs, though it is likely that they will buy as much anthracite as they can get at the same time. If the way they are clamoring for it here is an indication, they would buy several years' supply if they could get it.

It appears that country consumers are getting a better supply of anthracite than they did last summer. They do their own carting and are sometimes able to get a full supply on the asking. The distribution is not regulated exactly according to needs yet.

Anthracite shipments to the lakes are again confined to the larger ports, as most of the small ones are supplied for the time. The amount loaded for the week was 112,200 net tons, of which 65,500 tons cleared for Duluth or Superior, 38,000 tons for Chicago, 7300 tons for Milwaukee and 1400 tons for Port Huron. Freight rates continue firm at 48c. to Duluth, 55c. to Milwaukee, 60 and 65c. to Chicago and $1 to Port Huron.

DETROIT

Shrinkage in coal receipts continues. State fuel administrator and county representative clash. Lake trade lacks volume.

Bituminous—Though the daily average of coal receipts in the Detroit market in May fell below that of the first four months of the year, a further reduction in volume of shipments is taking place this month. Receipts for the first week of June are said to average about 420 cars a day. With so greatly curtailed a movement of coal into the city now, when conditions are perhaps the most favorable of the year for liberal shipments, jobbers and consumers view the outlook for next winter with apprehension, fearing there will be a shortage of coal that will result in much suffering for many people.

The disagreement between W. K. Prudden, state fuel administrator, and Edgar B. Whitcomb, his Detroit representative, who is chairman of the Wayne County fuel committee, reached an acute stage a few days ago, when Mr. Prudden, in a letter from Lansing made peremptory demand that Mr. Whitcomb resign. Mr. Whitcomb declined to do so and appears to have the support of the coal committee of the Detroit Board of Commerce. The immediate cause of the strained relations was the attitude of Mr. Whitcomb and his associates on the Wayne County committee in opposing as too low a $2.50 a ton margin, allowed Detroit dealers by Mr. Prudden for domestic coal delivered through the summer. Coal men say there has been a lack of harmony between the state and the local fuel administrations for several months.

Anthracite—Shipments of anthracite coming into Detroit are far short of the needs of domestic buyers, and few of the consumers have been able to get delivery of anthracite for next winter's needs. While demand from the household consumers continues active, there is no sign of improvement in supply. Efforts are being made through the Detroit Board of Commerce to obtain a larger allotment of both anthracite and bituminous.

Lake Trade—Movement of coal over the lake routes is disappointingly light. With lake cargo coal prices fixed by the Federal Fuel Administrator late in the week, shippers and vessel owners are hopeful a larger volume of shipments will be delivered at lake loading docks from now on, making possible an early finish of coal shipments to the Northwest. So far shipments have been much below expectations though carrying capacity is plentiful.

COLUMBUS

Activity prevails in the Ohio coal trade. Lake requisitions are large, and the same is true of the demand from steam and domestic users.

Reduced car supply and growing labor shortage in several mining districts of Ohio is reducing the output materially. As a result the records of production are falling behind, and it is estimated that the shortage during May was about 1,000,000 tons. But this state of affairs is expected to be remedied in part, and it is believed that under coöperation between the railroads and the Federal Fuel Administration an increase in the output will be noted soon. Demand for all grades is strong, and the Lake trade is especially active. The tone of the market is generally satisfactory.

The Lake trade is now absorbing a large tonnage, variously estimated from 50 to 70 per cent. of the entire production of Ohio mining fields. The remainder of the tonnage is distributed among steam users and the domestic trade. The vessel movement is good and with it the ore movement is growing. Lake trade is expected to be pushed without the use of a Lake priority order, although shippers would not be surprised to learn of a priority Lake order by mid-season. Reports show that the tonnage to the Lakes is about 1,000,000 short of anticipations earlier in the season.

The domestic trade is active in every respect. Dealers are placing orders both for immediate and later shipment. Their reserve stocks are generally depleted, and they have not sufficient supplies to take care of all business booked. Pocahontas is a scarce article in the local trade. There is considerable West Virginia splint on the market, however, and New River coal is also being offered. The main supply for domestic purposes is coming from the mines of the Hocking Valley, Pomeroy and Crooksville. There is a slack in the demand for Jackson lump. "Fuel Week" caused an appreciable increase in the domestic demand.

The steam business is still one of the best features of the industry. Large steam users are endeavoring to stock up to guard against an emergency and consequently they are buying more than current needs warrant. The smaller users are following the example of the larger consumers whenever they have available storage space. There is little extra mine-run or screenings on the market, as it is readily absorbed.

CINCINNATI

Storage demand continues at a heavy rate, and dealers are unable to take care of orders. Improvement in transportation conditions is noted and may help the situation.

With a demand for coal which breaks all records for this time of the year, the trade is still running behind on deliveries, with no immediate prospect of catching up with its orders. The retail trade has been compelled to adopt the expedient of numbering its orders and notifying its customers that delivery will be made as their numbers are reached, and at prices then prevailing. Receipts are reported as somewhat improved during the past week, in spite of the growing volume of the movement to the lakes, which normally takes the bulk of the coal going through this gateway during the summer season. This movement, in fact, is expected to be the principal obstacle to the local demand being fully satisfied during the summer, inasmuch as it is the policy of the Fuel Administration, as established last season, as well as the natural policy of the operators, to move coal forward to the Northwest while the lakes are open for navigation. Dealers who look ahead, therefore, are still uneasy over the possibility that they will not be able to secure enough coal during the summer to satisfy the demands of local consumers. However, more coal than usual has already been placed in storage, and to that extent the possibility of a shortage next winter has been disposed of.

LOUISVILLE

General demand for all grades of coal greater than supply. Eastern Kentucky coal scarce in Louisville due to heavy gas demand. Domestic stocking heavy.

A prominent coal jobber in discussing the situation said: "There are easily orders to be had for one hundred domestic lots of eastern Kentucky coal for one that is being filled. Gas, run-of-mine and domestic coal are all in big demand. Domestic consumers are buying steam coal even at this season. There is practically no gas coal to be had, as the mines are sold up."

A western Kentucky operator said: "The draft has interfered with us considerably through breaking up our clerical organizations. The labor situation is critical, and due to the shortage of cars we are losing many men, who are going to farming. The car supply at present is about 50 per cent. of requirements. The demand is good and all grades are selling easily, but we haven't the production necessary under existing labor conditions."

In eastern Kentucky the mines at present have about a 75 to 85 per cent. car supply, which with a full supply of labor would be reduced to about 50 per cent. Cars are not making the usual mileage as they can't be loaded out fast enough with the short labor supply, and this has increased the car supply, but not the production.

BIRMINGHAM

Troubles in local market all center around the short coal supply. Inquiries for domestic and steam are holding up well in excess of available tonnage. Output averages around 75 per cent. normal, due to lax working conditions, and, in a measure, labor shortage.

The complaint in local trade circles is almost totally centered on the shortage of coal to supply the demand for both domestic and steam product. The cause of this shortage is attributed almost wholly to the indifference of mine workers to the situation and the dire need for 100 per cent. efficiency in coal production. More labor could unquestionably be used to advantage at many operations, but there is little or no hope for betterment. Every measure is being taken to induce the organizations at the mines as now constituted to refrain from laying off from one to three days per week and work steadily at least five and one-half days, and the success of such efforts would result in a wonderful improvement in the coal supply. The output has been gradually dropping off for the past several weeks, and unless the situation is speedily retrieved the 1918 production will fall under that of 1917.

Consumers will face an increase of 15c. per ton in the delivered price of coal on and after June 25, when new freight rates are effective. The demand for steam coal from Georgia territory slackened slightly during the past week, due to a more liberal supply being received from the Kentucky-Tennessee fields, but inquiries from the immediate district and within the state have shown no diminution. Calls for lump coal are strong and insistent from every section of the zone. The retail trade is good and deliveries are almost on a par with receipts at local yards.

Coke

CONNELLSVILLE

Connellsville output unchanged for six or seven weeks. Prospects of more coal production but perhaps less coke. Screenings from dumps bring better prices.

Production and shipments of Connellsville coke continue at about the same rate as for six or seven weeks past, about 340,000 tons a week. Shipments of Connellsville coal, for byproduct coking, have increased a trifle. The blast furnaces are not fully supplied with coke as yet, but this desired condition is now nearly attained. Few furnaces actually in blast are suffering from lack of coke, but the majority are unable to accumulate any stock as a margin of safety. Several furnaces tributary to the Connellsville region are out of blast because there is no assured supply for them.

From the outlook it seems improbable that there will be any material increase in the output of Connellsville coke, and if the blast furnace industry gets more coke in

future it will be through the medium of the byproduct oven. The probability is that as a large number of byproduct ovens are completed in the next few months the production of Connellsville coke will decrease, although the production of Connellsville coal, for byproduct coking, may increase in greater ratio.

There will be scarcely any change in the alignment of contracts over July 1. A few contracts that were to expire June 30 have been renewed, but they were merely contracts that called for a regular supply at the going price. The market remains quotable at $6 for furnace, $7 for foundry, 72-hour selected, and $7.30 for crushed, over 1-in., per net ton at ovens. The industry of screening the old dumps in the region is expanding, and as the contractors doing the work are particular about the product, they are selling the screenings at still higher prices. When this industry first appeared, a couple of months ago, the screenings brought about $4, but now they are sometimes bringing as high as $6.50. The Government limit would be $7.30, as the regulations are construed.

The "Courier" reports production in the Connellsville and lower Connellsville region in the week ended June 1 at 343,020 tons, an increase of 2920 tons.

Buffalo—The consumers of coke of all grades are complaining of shortage and are having difficulty in getting what they need, but they have not shut down and probably will not need to, for there is some to be had as yet. The jobbers as a rule get only the refuse breeze coke, but they can sell it for steam-making as fast as it appears. One jobber reports shipping 10 cars to New Hampshire lately. Iron ore comes in liberally. The amount received here to the end of May was 802,210 gross tons, as against 548,299 tons to the same time last season.

Middle Western

GENERAL REVIEW

Production insufficient to take care of the demand. Many dealers have orders that will keep them busy far into the fall.

An alarming condition prevails in the coal-producing sections due to the constant drain upon the man-power by the army draft. In some sections operators are badly handicapped for men to drive motors, and they also have lost heavily of their mule drivers and trackmen. The fact that good drivers are scarce and hard to get in normal times would be sufficient evidence of the seriousness of the present situation, when almost 50 per cent. of this class of labor has been drafted.

Tonnage produced during the past week has shown an improvement over the previous week, with an average of 77 per cent. equipment supply. In some sections more cars were available than could be loaded, while in other localities many hours were lost owing to lack of cars.

CHICAGO

Demand still heavy for prepared coal. Screenings moving slowly at an off figure.

There is no let-up in the demand for prepared coal produced in Illinois and Indiana, and many operators would be able to operate their mines to full capacity if they did not take another order in six months. Particularly is this true of miners in Saline, Williamson and Franklin County, Illinois. Central and northern Illinois screenings have been a drug on the Chicago market for the past week. Indiana fine coal has also been selling slightly off.

The curtailment of anthracite has been helpful to Illinois mines, and the fact the public now realizes that no Eastern bituminous can possibly reach this market makes a market situation that is far in excess of anything ever heretofore dreamed of.

Quotations in the Chicago market are as follows, per net ton f.o.b. cars at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Springfield	Carterville	Grundy, La-Salle, Bureau and Will.
Steam lump	$2.55@2.70	$2.55@2.70	$2.95@3.10	$2.55@2.70	$2.55@2.70	$3.25@3.40
Domestic lump	2.55@2.70	2.55@2.70	2.95@3.10	2.55@2.70	2.55@2.70	3.25@3.40

MILWAUKEE

Fuel administrators disturbed over the outlook for an adequate supply of coal. Efforts being made to accelerate Lake shipments. Consumers warned of a prospective shortage of anthracite.

Fifty-nine cargoes of coal, aggregating 448,563 tons, were received at Milwaukee during the month of May. Of this amount 85,066 tons were anthracite. During the first ten days of June the receipts amounted to 164,430 tons, of which 22,497 tons were anthracite. This is not a bad showing, but the fact that the docks were bare at the opening of the present season, whereas last year there was a goodly amount of anthracite held over, makes those having the fuel supply in hand somewhat nervous. State Fuel Administrator Fitzgerald is fearful that this part of the country will receive only two-thirds of the usual supply, and he has gone to Washington to stimulate the coal movement to the Northwest if such a thing is possible.

Consumers in the city and throughout the state are being warned that they may be forced to resort to soft coal to the extent of at least one-third of their regular allotment. Operators of power plants are also being notified that they will have to practice the strictest economy in the use of fuel. Mr. Fitzgerald will appoint an advisory engineer whose duty it will be to check all needless waste of fuel in power plants. It is figured that a saving of from 10 to 20 per cent. can be made by this means.

Notwithstanding that a fair amount of anthracite has been received thus far, only one company in Milwaukee is making deliveries of this grade of coal. The other yards are holding back until prices have been fixed by the Government. Just as soon as the price schedule has been received Mr. Fitzgerald says deliveries by coal dealers will be made compulsory. The books of small coal dealers are filled with orders, which they are unable to take care of because the dockmen are holding the coal from the market.

The steamer W. B. Davock unloaded 7000 tons of hard coal in 8 hours and 40 minutes at Sheboygan, Wisconsin.

ST. LOUIS

Car supply improved and a slight improvement in transportation. Carterville and Duquoin shipments light, Mt. Olive normal, and Standard overproduction continues. Domestic demand continues good, with light steam buying. Outside coals practically shut out from this market entirely.

The market at the present time continues without much change. There has been an improvement the past week in the car supply on all lines in all fields, due perhaps to the fact that transportation shows considerable improvement. There are quicker deliveries on coal from all fields than there have been for some time past.

In the Carterville field a heavy tonnage is being taken for railroad purposes. This, in the estimation of large buyers and the public in general, is not a proper procedure, for this high-grade coal is hauled by the railroad through the Standard and Mt. Olive fields for railroad purposes when the Standard and Mt. Olive coal would probably fill the bill to the same extent. Carterville coal is more valuable for domestic and other purposes than for railroad fuel, and the feeling on the part of the public is that the proper authority has not been exacted in compelling the railroads to take the kind of fuel that is best adapted for them.

The same condition prevails in the Duquoin district. The car supply is much better, but the labor problem is going to be a serious one shortly, with the draft making inroads. The month of June will see a decreased tonnage in all mines in the entire field on account of the draft.

The Mt. Olive field continues normal. The car supply is good, movement is fair, and the labor supply, while not all that could be desired, is maintaining a good tonnage at all mines. The demand for this coal is about equal to the supply at this time.

The Standard field continues to have an over-production. There is no market for screenings, which are down as low as $1.40. Mine-run is going at about $1.90 to $2 and lump coal is as low as $2.20, whereas the Government maximum is $2.55. The other miscellaneous sizes correspond, and the operators will not push production because it means the fixing of lower prices. In the face of this there comes an insistent demand daily from users in western Missouri outside of the Illinois zone for this same coal.

The railroads are not buying. They are hauling Carterville and Duquoin coal through the Standard field, where the mines are idle and where unbilled coal remains on track, and the Carterville mines are almost 100 miles farther away than the Standard field mines.

A few straggling cars of anthracite continue to come through, but this will all be shut off after this week. There is practically no Arkansas coal coming in and the local market is trying to load up on coke. The prevailing market is per net ton f.o.b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.90	$2.55@2.70	$2.55@2.70
3x6-in. egg	2.55@2.90	2.55@2.70	2.55@2.70
2x3-in. nut	2.55@2.90	2.55@2.70	2.55@2.70

Williamson & Franklin County rate is 87½c. Other fields, 72½c.

SEATTLE

Greater demand to be made for Washington coal, and shortage in fall and winter predicted unless fuel is stored during summer.

Though the State Fuel Administration has reports showing that the mines of Washington could produce 1,500,000 more tons of coal during the year than in 1917, it is seriously questioned whether or not this record will be made. Unless it is made there will be a serious shortage, for it is estimated now that the increased demand upon Washington mines will total 1,250,000 tons during the year. The consumption last year was 4,161,000 tons, and the estimated consumption this year is 5,411,000 tons, with an estimated production of 4,600,000 tons.

The coal operators will have to overcome a labor shortage already existing and likely to become worse if there is no coal buying during the summer months. Already the United Mine Workers of America, District No. 10, report that during one week last month 500 members went into the shipyard work as assuring steadier employment. The crews of many of the Washington coal mines are bein scattered, and it is going to be a problem to secure enough men when fall demand begins.

The fact is, coal operators, railroad officials and the Fuel Administration agree that the West gradually is being drained of its supply of freight cars to supply Eastern demands. If the cars were in service here, it is pointed out, they could not be loaded with goods destined to Eastern lines. Since the cars are not in use in coal service they are being taken for other shipments, and once they reach an Eastern line the chances of their return grow slim.

Washington coal mines last year had little real responsibility beyond supplying a part of this state's requirements. During the coming year it will be asked to not only supply its own needs but those of Oregon and Alaska, with incidental supplies for other territory. Washington has never had to store coal. Under the most severe circumstances the state has managed in some manner to get fuel from near-by mines before it suffered. For that reason, the mines, large dealers and big consumers have not provided storage facilities. The coal business of Seattle is split up among 104 retailers, exclusive of teamsters. Because of the shortage in storage room it is insisted by those who are handling the fuel problem that every bit of room will have to be used to provide against the winter's demands.

Practically all plants now burning oil will have their supply withdrawn by November, only a few war-essential industries being permitted to continue using oil.

COAL AGE

Volume 13 NEW YORK, JUNE 22, 1918 Number 25

People Worth While

By FLOYD W. PARSONS

MONDAY evening in Washington I had dinner with a real American—an editor and writer of national repute. He had given up an enviable position affording him comfort, safety and family associations to serve his country.

This man is no longer young. He has a wife he loves and a boy in his teens. Yet in our present crisis he could not remain at home. Few men worked harder than he did, but for months he had worried because he was only helping indirectly.

Within him there was a conflict with conscience, and the mental struggle made him a shadow of his former self. Day after day he pictured the future, and in his vision he saw himself an embittered old man who had failed his country in its hour of need.

This was too much. He went to Washington, got into a uniform, and will soon be "over there." Once again he is happy, for he knows now that the wife and boy who understand will be proud some day when "dad" comes back.

In comparison with such nobility how mean are the profiteers and how despicable the slackers, old and young. Sacrifice for material gain is not sacrifice at all. When this war ends, America will have new standards for the determination of high breeding. An inability to pick the right fork at a society dinner will no longer be the sole measure of a citizen's character. The true patriots will be those who have found a satisfactory reward in the self-consciousness of duty well performed.

Through what process of reasoning can anyone arrive at the conclusion that this war is only a fight of the men and women who have gone to France? Every drop of blood shed by American soldiers on the battle front calls for a thousand drops of perspiration on the brows of American workmen toiling in our mills and mines.

Let us label as traitor every man today who can work and doesn't. Let us brand as disloyal every company and every corporation official who now attempts to exploit workmen under the guise of patriotism and the Nation's need. Let us avoid association with all men and women who are false to our Government and to freedom's cause.

The heat of midsummer is now upon us, and the miner does not live who would not rather roam the woods, or fish, or swim, or lounge in the shade than dig coal in the dark recesses of Mother Earth these wonderful days. But the boys in France have no choice. A bullet will pierce their heart as speedily when the thermometer registers 90 as when the snow covers the ground.

We, likewise, have no choice. Every man must work every day until there is enough coal to make all the guns, shells and ships necessary to destroy German autocracy and forever end the rule of men who laugh at treaties, and who through rape and murder have added a new meaning to the word "frightfulness."

Let us no longer view our country as a certain area of land with mountains, rivers and woods, but as a principle based on humanity and justice. Never was there a time like the present for the coal miners of America to serve, not only the nation, but humanity at large. If the men who mine coal lay down today our cause is lost. What is needed now is simple, unadorned, unpurchasable, incorruptible loyalty; and that means work every minute every day when there is an empty car to load with coal.

IDEAS AND SUGGESTIONS

Winding and Forming Armature and Stator Coils

By Frank Huskinson
Lafayette, Colo.

An important pump motor burned out so badly recently that it was necessary to rewind it completely with new coils. Not having any coils on hand, and as it would take months to get them from the factory, I decided to make up a set. With slight variations, the methods I used can be employed to make up a set of armature or stator coils for almost any motor.

The motor in this case was a 25-hp., 440-volt, three-phase, 60-cycle machine, with 72 coils. In Fig. 1 is shown the stator without the windings, except for one coil placed in the slots to show the proper span. The coils were rather difficult to make on account of the shape, there being two No. 13 wires in multiple, eight turns per coil, two wires in width and eight wires in depth. In making up the coils I used the winding device shown in Figs. 4, 5 and 6. I wound the proper number of turns and then secured the wires with heavy tin clips at four points, so the whole would retain its shape. In taping the coils the leads were first insulated with cotton sleeving and the linen tape was started at one of the leads. Holding the coil in a vise, the tape was wound on, the tin clip being moved just ahead of the tape. After a portion of the coil was taped the clip was removed and placed on the coil over the tape. This was necessary in this case on account of the flat shape of the coils. The heavy tin clip held the wires in their proper position; otherwise the coil would have buckled and become just a bunch of wires without any semblance to a coil. All the coils were taped, given a dip in thin shellac varnish and dried before forming to their proper shape.

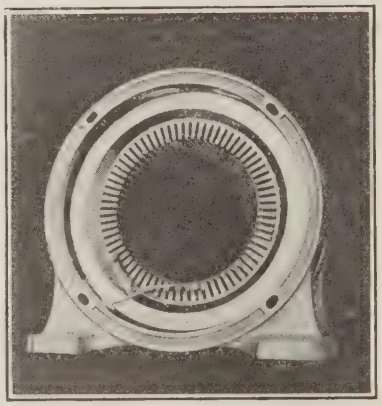

FIG. 1. STATOR WITHOUT WINDINGS
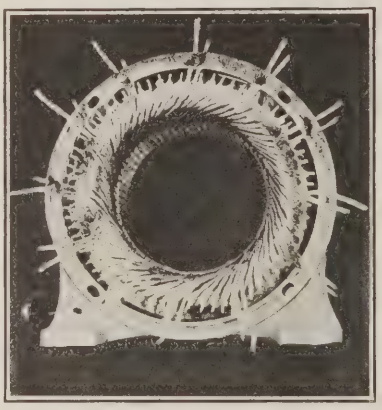
One coil is placed in the slots to show the proper span



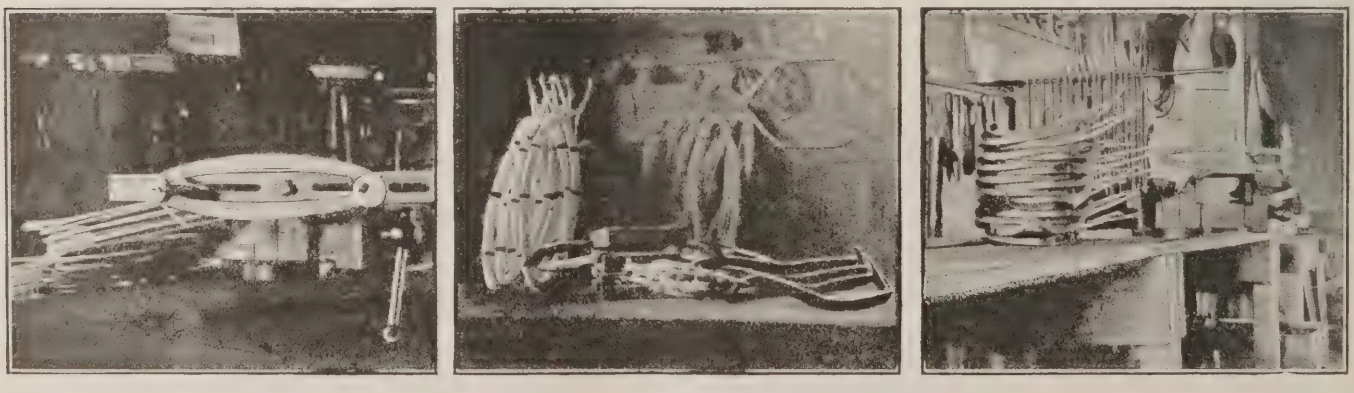


FIG. 2. STATOR WITH WINDINGS
The coils are in place and the group connections made

To form the coils to the proper shape a former block was made out of a suitable piece of wood, as shown in Figs. 3, 4 and 5. The bottom half of the former block was fastened in the vise, the bottom half of the coil was centered in the block, and then the top half of the block was centered on the top half of the coil. The top half of the block was then pressed down and shoved over to the stop block. Holding the blocks in this position the ends of the coils were bent downward as far as necessary to get the proper shape. It requires only a few seconds to form the coils to shape. The whole operation is simple, and each coil is a duplicate of the other. In Fig. 6 is shown the details of the adjustable coil-winding tool and the forming blocks used for this particular job. It is only necessary to change the dimensions of the forming blocks in order to shape any desired coil. I make a set of forming blocks for each style of armature or stator coil that I have to wind. I then mark the forming blocks and put them away for future use. Also, in winding a set of coils for the first time, I wind two extra coils. One of these I finish up complete, the other is left just as it comes off the coil winder. These two coils are kept with the forming blocks, so that all the necessary data and information on that one particular style of winding is at hand with the necessary forming blocks, and a new

FIGS. 3, 4 AND 5. OPERATIONS IN WINDING AND FORMING ARMATURE AND STATOR COILS

set of coils can be made up therefrom at any time. The adjustable coil-winding tool, shown in detail in Fig. 6, has a broad range of adjustment and can be used for almost any style or size of coil by simply setting the tool to the desired size. The disks are adjusted to the proper width and depth of coil. The center distance is adjusted to suit the requirements.

It is a simple and easy matter to wind coils rapidly

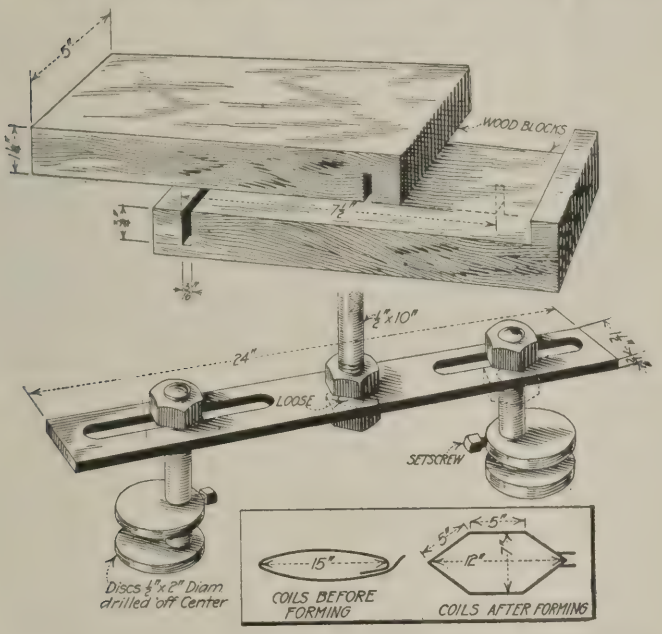

FIG. 6. DETAILS OF WINDING TOOL AND FORMING BLOCKS

and effectively with this coil-winding tool, and for giving the coils their proper shape there is nothing simpler than the forming blocks described. In Fig. 2 is shown the same stator illustrated in Fig. 1, with the coils all in place and the group connections made. This stator is completely finished, with the exception of the cross-connections and the phase connections.

Proper Housing of Mine Labor

The general manager of a large anthracite operation took me through a group of modern houses recently completed for his workmen. While he pointed to the improvements with considerable pride, he also spoke of the uphill struggle to teach certain foreign labor modern ways of living. It is not encouraging to go through one of your new houses and find an enameled bathtub filled with coal.

There are two ways to meet this problem. One way is to drop back to the workman's living level and build his house accordingly. The other way is to attempt to improve his domestic habits, and it may be well to add that the latter method is far from easy.

The wives and daughters of mine officials can and do play an important part in this work. They can accomplish results where men would meet failure; and yet a point is reached where even they are handicapped by the wide social gulf between them and the foreign workman's family.

The wife of a prominent coal operator who devotes much of her time to this important work is attempting to meet the difficulties with a New York architect skilled in housing labor. They erected modern houses and determined to lift the foreign element among the miners to our American ways of living. A scheme was tried of giving one house in a row rent free to an American family to be an example of cleanliness to the foreign neighbors. But the neighborhood got wind of this and refused to be decoyed into decent living. These foreigners seem to be shy of anything having the appearance of organized uplift. Thwarted in this plan they have resorted to bribing selected foreign families to be neighborhood models, but success depends upon the arrangement being kept secret. Where there are children in the family the foreigners are easier reached, as the youngsters carry American ideas home from school.

Those who have had the widest experience in work among this class know that great patience is necessary. It is no easy matter to uproot methods of living which have been handed down for generations. After unceasing efforts, you are encouraged by signs of improvement and you imagine the force of the old habits is yielding to treatment. Then there is a slump and you must start all over again. The discouraging thing about the work is the way these people can vary the form of their uncleanliness. If you succeed in correcting one bad habit it is apt to crop out elsewhere in an entirely different form, but the same old habit just the same. For instance, you persuade them to stop giving animals free run of the house. On your next visit you are impressed by the clean appearance of things. In passing a bed you wonder why wire netting is strung around the four posts near the floor. Looking closer you are apt to find that chickens are being kept under the bed. But patience and the right methods win in the end.

What Is Meant by Specific Heat?

By W. D. Owens
West Pittston, Penn.

What is mean by specific heat when this term is applied to material bodies? Water is with one exception supposed to be the most difficult of all substances to heat. The exception is hydrogen gas, which requires 3.40 times as much heat to raise its temperature over a given range as does water. But water is the standard by which other substances are compared. The increment of heat necessary to raise the temperature of water 1 deg. is called unity, or water is said to have a specific heat of 1; hydrogen, therefore, has a specific heat of 3.40.

All other bodies known require less heat to raise their temperatures 1 deg. than does water, therefore their specific heat is written as a fraction, usually expressed decimally. For instance, the specific heat of steel is 0.11 or 11 per cent. of 1. The specific heat of silver is 0.055, while that of gold is only 0.03. Air is more difficult to heat, its specific heat being 0.2375; that of carbon dioxide is 0.2183, while that of methane gas, or firedamp, is 0.593.

Where the term specific heat is mentioned the reader will now understand that it is the ratio of the amount of heat required to raise a given weight of any given substance (say 1 lb.) through any given temperature range (say 1 deg. F.) to the amount of heat required to raise the same weight of pure water through the same range of temperature.

Present Illinois Coal-Mining Industry

By GILBERT H. CADY
Urbana, Illinois

SYNOPSIS—*The coal-mining industry in Illinois is flourishing. Since 1900 the output has tripled and the percentage of machine-mined coal is steadily increasing. Stripping activity is also becoming pronounced. Large operations are becoming more numerous. The recovery of pyrite has not as yet received serious attention.*

STATISTICS recently published by the Illinois Department of Mines and Minerals, and general information coming to the attention of the State Geological Survey, furnishes abundant evidence of the flourishing condition of the Illinois coal-mining industry. The mines are working as large a proportion of the time as ever before, and an increasing number of operations of large capacity are being opened. The use of Illinois coal is being forced upon many consumers, many of whom probably will never return to fuels formerly used.

This and the additional fact that large corporations having a rather steady demand for coal have entered the mining field doubtless exercises a stabilizing influence which promises well for the future. The following review and summary of statistics compiled from the 1917 Coal Report of the Illinois Department of Mines and Minerals, with other information available, it is thought will be of interest as indicating the present condition and trend of the industry. The statistical data are summarized in Table I, which reveals interesting facts which may be listed briefly as follows: Since 1900 production from all mines and from shipping mines alone has tripled. The amount of machine-mined coal has increased more than eight times. The total number of employees has doubled since 1900, but the number of miners has been steadily decreasing since 1909. The number of shipping mines was steadily decreasing between 1906 and 1915, but has been slightly increasing during the last two years. The number in 1917, however, was only one more than the number in 1900. Since 1900 the number of mining machines has increased nearly five times and the average annual

capacity of a machine has nearly doubled. The average number of days during the year in which shipping mines are in operation varies between 169 and 222, or between 64 and 74 per cent. of full working time of 300 days. Since 1906 the average number of shipping mines abandoned is 33. This rate of closure indicates a present average length of life of each shipping mine of about 10 years. The average number of new mines annually is between 19 and 20.

The statistics reveal a decided speeding up of production per mine in the last decade. This seems to have been brought about in a number of ways. The most evident source of the increase in production is in the increase in the number of mining machines. It may be noted that about four-fifths of the entire increase in production between 1900 and 1917 can be assigned to increase in the amount of machine-mined coal. Of the total increase of 54 million tons in those years, 42 million represents the increased tonnage mined by machines. It is also noteworthy that the effectiveness of the mining machine has greatly increased, so that in 1917 each machine produced twice the tonnage of the individual machine in 1900.

With the more widespread use of mining machines has gone the more general introduction of motor haulage, and probably also, though the statistics do not show it, an increase in hoisting efficiency. The increasing efficiency of individual mines during these years is indicated by the increase in the output of a mine near Gillespie, which in 1907 led the state with a production of 699,127 tons, and in the fiscal year 1916-17 had an output of more than one million tons.

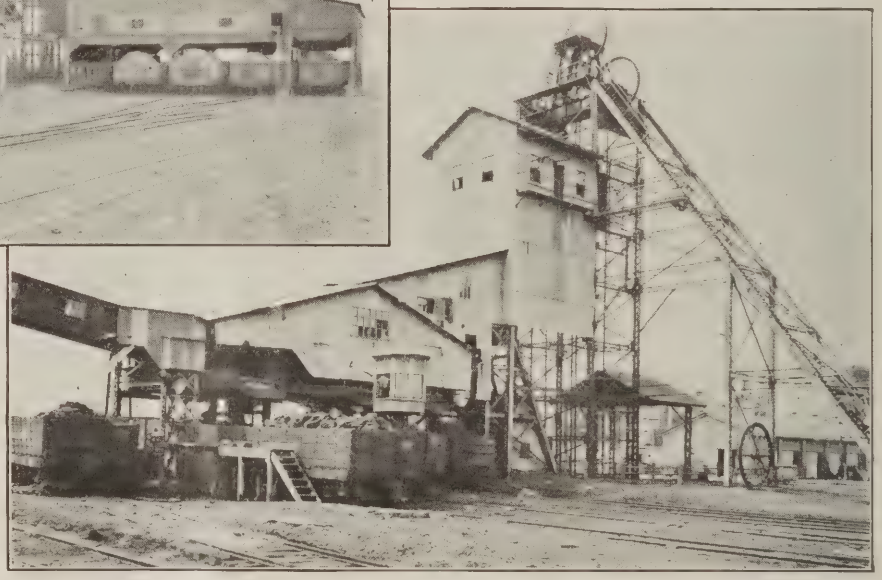
A further cause of increasing production probably lies in the increase in the number of large operations. The tendency along this line is indicated by the figures given in the 1917 Coal Report. It is shown that the number of mines annually producing 200,000 tons or over has increased from 27 to 139 since 1900. The five largest mines in the state have each a production of between one million and 1,200,000 tons. Of the new mines being built or completed since June 30, 1917, at least four are planned for an annual production of more than one million tons. In comparison it is of interest to note that the total capacity of the four mines abandoned since June, 1917, was only about 600,000 tons. It is evident that operations of the larger type are meeting with much favor among operators. It should not be inferred, however, that large mines are necessary for efficient operation, for some of the smaller mines are being profitably worked.

The growth in number of the large 5000-ton mines is necessarily slow because of the large investment represented in the development of such properties. The recent more rapid increase in their number has been brought about by the entrance into the mining industry of Illinois of such wealthy coal-consuming companies as the United States Steel Corporation, the Standard Oil Co., the Byproducts Coke Corporation and the Chicago, Burlington & Quincy Railroad.

Increased productivity of Illinois mines besides being in part due to the increase in the number of machines and of large operations, is also due to the more general use of the most modern mechanical devices. Hoisting by skip is being introduced. In one of the large mines now being opened much modern equipment is to be installed, such as an electrically hoisted skip operated from the shaft bottom, a rotary dump, entry-driving machines and loading machines, besides the usual complement of chain cutters and electric locomotives commonly found in machine mines.

The desire to produce the coal with the greatest possible speed has resulted in one of the fields, at least.

SHAFT HEAD AT A FRANKLIN COUNTY MINE



in a decrease in the percentage of recovery. In certain parts of the state, particularly in the Franklin-Williamson Counties field, the percentage of recovery has always been relatively low. Pillars have not been systematically pulled and, furthermore, where the coal is thickest the roof is regarded as poor, so that the top bench, having a thickness of 3 to 5 ft., is commonly left in the mine and is rarely ever recovered.

Recently it is becoming the practice of a greater number of mines in the area of thick coal not only to leave the roof but also to leave from 1½ to 3 ft. of coal in the floor below a persistent thin clay parting known as the "blue band." By so doing the chief source of clay impurity is not disturbed in the mining, and a product somewhat better than the average coal for the region is produced. Such coal has an enhanced reputation at least among domestic consumers, and in addition to its probable trade value the practice results in speeding up production and in decreasing the need of coal-cleaning operations at the shaft head.

More especially in the last 18 months than formerly, increasing interest has been manifest among coal operators and consumers concerning the variations in quality of Illinois coal. Probably part of this interest has been created by the large body of analytical data appearing in the publications of the State Geological Survey and the Illinois Coal Mining Investigations.

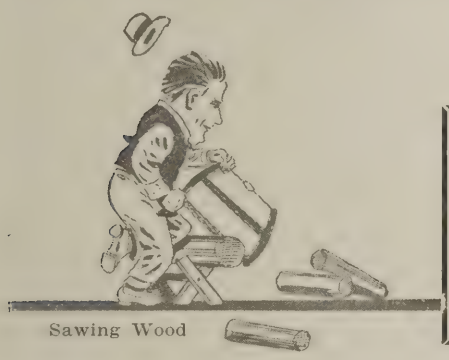
A working basis for the purchase and sale of Illinois coals on specification has been proposed in one of the publications by Prof. S. W. Parr. This plan recognizes the distinctive variations in the quality of the coals and has tended to establish a reasonable differential between coals of different rank. The purchase and sale of coal on specification is becoming more generally the practice, possibly to a large extent because Federal and state purchases are made on such a basis. One of the probable effects of this growth of the appreciation of the difference among Illinois coals is the decided movement of the center of production of the state toward the southern counties of the coal field.

In addition to the more definite knowledge concerning the chemical difference existing among the coals of the state, there has also come a better knowledge of the adaptability of the coal to specialized uses. Of significance along this line have been the experiments, largely of a private character, toward proving the adaptability of Illinois coal for making metallurgical and other coke. The results of these tests may be judged from the fact that large companies such as the United States Steel Corporation and the Byproducts Coke Corporation have recently made purchases of large properties in the southern Illinois fields, and from the fact that several byproduct coke plants in the Middle West now use Illinois coal for part of their charge. Of interest also is the recently announced plan of certain Chicago coal men to build a large experimental low-temperature coking plant for the manufacture of byproducts and a smokeless fuel.

The adaptability of Illinois coal of various grades to use in gas retorts has been the matter of recent investigations and experiment by the United States Bureau of Mines under the Illinois Coal Mining Investigations Agreement. Because of the increasing difficulty in obtaining supplies of eastern gas coal, many companies have been considering the possibility of using Illinois coals for at least part of their requirements. It has been demonstrated that the substitution can be made, and should the companies become accustomed to the use of Illinois coal at this time a certain percentage of them will doubtless continue its use because it will be relatively cheaper.

The recent agitation to accomplish a greater production of pyrite or coal brasses as a byproduct in coal mining has as yet yielded insignificant results in Illinois. There is a decided tendency on the part of the operators to withhold financial investment in what is regarded as an uncertain industry pending definite assurance of sufficient stability in the market to allow for the re-

covery of the outlay. Investigations by members of the State Geological Survey and the United States Bureau of Mines have substantiated a previous belief that a large supply of pyrite can be obtained from Illinois mines under a guaranteed price of not less than 30c. per unit or about $12 per ton for pyrite containing about 40 per cent. sulphur.



The desire to meet the increasing demands of the trade during the last few months as quickly as possible has resulted in considerable activity in the areas where stripping coal is available. Numerous new operations of this sort have been started along the southern edge of the coal field from the vicinity of Duquoin eastward nearly to Harrisburg along the outcrops of No. 6 and No. 5 coals. The greater number of these operations are between Duquoin and Marion on No. 6 coal. Some new stripping operations have been opened in Vermilion County, and there is considerable interest manifest as to the availability of coal in other localities, especially in St. Clair and Fulton Counties and in the longwall field in the northern part of the state.

Interest in the undeveloped resources of the state is indicated by numerous inquiries which are naturally directed to the Geological Survey. These inquiries have been much more numerous during the last 8 to 12 months than previously. Inquiries concern areas possibly underlain by the thicker coals, that is, coals 5 ft. thick or more, which lie in the southern or central part of the state.

There has been considerable exploration work in Madison and Macoupin Counties incident to the transfer of a large body of coal land near Carlinville. Aside from the drilling in this part of the state no considerable amount of actual exploration work has been done. Certain areas in Washington, Christian, Clark and Crawford Counties seem to be under special consideration by more than one company. The extension of the Indiana field into Clark and Crawford and possibly Lawrence Counties, Illinois, seems to be altogether probable. This would represent, however, an entirely new field in Illinois, and the possibility of its development is therefore of special interest.

British Coal Output

The British Home Office has issued some details of the output of coal in Great Britain for the year 1917. It appears that production, which from 287,411,869 tons in 1913 fell to 265,643,030 tons in 1914 and to 253,179,446 tons in 1915, rose in 1916 to 256,348,351 tons, but in 1917 fell again to 248,473,119 tons, a decrease of 7,875,232 tons from 1916. The number of persons employed at mines under the Coal Mines Act of 1911, which is one of the principal statutes regulating the working of British coal mines, was 1,021,340. This figure shows a decrease of 106,550 persons on the prewar year of 1913, but an increase of 23,277 persons on the figure for the year 1916. The rate of the decrease on the prewar figures in the output of coal is about 13.5 per cent., and in the number of persons employed at mines of about 9.4 per cent. The total number of persons employed will of course be considerably less in the near future, owing to the necessity of meeting military requirements. The release of 100,000 men from the mines as a preliminary step is already in progress.

The Patriot

By RUFUS T. STROHM

Every city, town an' village
  Has a lazy, loafin' bunch,
An' they all allow they can tell just how
  We should land the winnin' punch;
An' they think they're patriotic,
  As they sit an' yap an' yelp,
But the good Lord knows that the talk that flows
  Doesn't do a mite to help.

Now, the real sort of feller
  Is a diff'rent breed of bird,
An' his only creed is the finished deed
  Instid of a shouted word;
For his common sense has told him
  That we're fightin' to the death,
So it's plain as sin, if he wants to win
  He has got to save his breath.

His monniker may be Tony,
  Or it may be Abe or Bert,
But sometimes his name is Marie or Mame
  An' the owner wears a skirt;
Yet you're allus sure to meet him
  Where the nation's pulses throb,
As he pegs away through the livelong day
  At his own pertickler job.

You can find him in the office,
  You can spot him in the shops,
An' he bares his arms on a million farms
  As he gathers in the crops;
But no matter what he's doin',
  He's strong for the common good,
An' there ain't a hint of a pause or stint,
  For he keeps on sawin' wood.

Some Experiences with a Borehole

By A. W. HESSE and K. M. QUICKEL

Heilwood, Penn.

SYNOPSIS—*In a borehole that was to be drilled for the purpose of connecting electrically a surface substation with the mines below, the casing had to be cemented in place with extreme care to prevent the draining of a spring. This article enumerates some of the troubles and difficulties that were encountered before an unobstructed water-tight passage was secured.*

THE drilling of an ordinary borehole and the placing of a casing therein for the purpose of dropping a cable from a substation to the mine below, does not usually cause much disturbance in the daily run of affairs—if all goes well. The experience secured in drilling and cementing a borehole, as here described, however, has some value, because of the conjecture as to what happens when a gas or oil casing is cemented through a coal bed.

To begin with, it is necessary to know just why the method here described was followed. The plot of ground purchased for the substation and borehole site was only a few feet from a spring which supplies the farming community in that section with water most of the year; and before the purchase could be made it was necessary to agree that this water would be prevented from leaking away through this borehole into the mine. Also the mine work was still 300 or 400 ft. away from the borehole.

Trouble Started with the Casing

The contract was let for the drilling, and on Sept. 5 the hole was ready to have the 6-in. casing placed and cemented. The contract called for an 8-in. hole, but when the 6-in. casing reached a depth of about 100 ft. it stuck. A measurement of the collars on the casing showed that the bit must have been allowed to taper down to less than 7⅞ in. By a compromise, it was decided to put in 5-in. casing. This was immediately ordered, and the drill was allowed to go to another job.

When the 5-in. casing came, a three-pole rig was erected and the casing started in; but at 105 ft. it also stuck! Apparently the hole had bridged and there was no alternative except to call back the drill. This was done; but the drill did not get back until the middle of November. The hole was reamed out and drilled 2 ft. deeper, making a total depth of 245 ft. The mine work had not yet reached the hole.

For fear that the cement grout would not get down far enough around the casing to seal off the water, it was decided to drop the cement into the hole before the casing was set on the bottom, then on dropping the casing bail the cement out of the casing and pour it around the top until the annular space around this pipe was completely filled to the top. One of the company's masons was placed on the job to mix the cement and see that the work was properly performed. He reported everything satisfactory.

The place driving to connect with the borehole reached the spot on Jan. 5, but found no borehole. The surveys showed careful work and were properly tied in, or proved. Having by this time lost all faith in the driller's reports, and noticing discrepancies between his data and the surveys, it was decided to sound to the miners by tapping on the pipe. The distance from the pit mouth to the borehole is over 1½ miles and, owing to various conditions, it was not until Jan. 29 that a party could be sent to the hole outside. One person in pounding on the hole with a brick let more than half of it drop into the hole. On Feb. 4 another man in sounding on the bottom of the hole with a puncher pick, found his pick caught when he attempted to pull it out, evidently because of the half brick, and finally broke his rope, leaving the puncher pick in the hole. That day the miners reached the hole and found that the casing was plugged with cement. The driller had failed to get his casing onto the bottom of the hole by about 8 in. and the cement had risen in the pipe about 27 ft., as was proved later. At the immediate bottom of the casing only sand was found. This sand extended about 4 ft. inside the casing and at least 20 ft. up the outside. Above the sand within the pipe came alternate layers of cement, cement grout and sand.

The attempt to force the cement loose in the pipe by means of a screw jack failed. We then tried fishing out the puncher pick so we could drill out the cement from above. This failed because of the overlying brick. We then decided to try driving the cement out by dropping a 5-ft. mine-locomotive axle on top of it. After dropping it from various heights, it was finally dropped 210 ft. and stuck in the cement so tight that the rope (¾-in., new) was broken. The next expedient was to drill the hole out from the bottom. A bit was made, gaged to 4 in., 1½-in. pipe was cut and threaded in joints of 2 ft., a set of iron clamps was made which held an improvised thread box, and a ratchet and threaded bar completed the equipment.

The Cement Had Not Set Hard

The cement was drilled out to a height of 26 ft. in 10 hours, showing that this material had set to a sort of fireclay paste consistency in three months' time. When the bit reached the puncher pick it caught, and no more cement paste could be got out. The next day water was poured in at the top of the hole, and the pick point washed out. We then tried to lift the axle with the drill rods and screw jack without effect. The bit was then put in and more material drilled out up to the axle. On Feb. 27 more water was poured in the hole in hopes of washing out the axle, but finding the water did not escape very rapidly, the pipe was filled to the top and allowed to stand.

The substation equipment not having arrived, it was not until Mar. 5 that we tried dropping a 200-lb. piece of axle on top of the one already in the hole. The 4 ft. of water then in the hole escaped rapidly, and the big axle moved about 8 in. Again, on Mar. 8, the axle was

once more dropped in the hole and, after several hits, the hole was cleared except for a little mud still clinging to the sides. This was easily removed from below.

It was still impossible to see daylight by looking up the hole from inside the mine, so to satisfy ourselves that the surveys were not off 11.8 ft., as shown inside the mine, we decided to determine, if possible, if and how much the hole had drifted. A flashlight was placed in a can and lowered in the casing. At 72 ft. from the top the casing was observed to bend, and at 105 ft. the light was just visible; while at 114 ft. not even a reflection was discernible.

We then took five cans of melted paraffin and lowered them in the fluid state to a depth of 100, 150, 180, 210 and 240 ft. respectively, and allowed the paraffin to harden while suspended at these depths. We then measured the tilt of the cans off the level of the paraffin and found the respective angles of deflection to be 2 deg. 35 min., 5 deg. 56 min., 3 deg. 40 min., 2 deg. 24 min. and 7 deg. 29 min. Upon platting these deflections on paper to a scale of 1 in. = 10 ft. we found that the hole drifted 11.7 ft. in the general course of the error found in the mine.

While the cement did not set to its proper hardness within the casing, its consistency on the outside was such that the hole is perfectly water-tight.

Combined Coal and Gas Firing

By M. Meredith
Liverpool, England

An interesting example of the mechanical firing of boiler furnaces with gas and coal is afforded by an installation in operation at the South Staffordshire Mond Gas Co.'s works, Dudley Port, Tipton, England. The plant comprises eight producers, each capable of gasifying 20 tons of fuel in 24 hours, and generating sufficient gas to drive internal combustion engines of 2000 hp. continuously. The total capacity of the present plant is thus equal to 16,000 horsepower.

The rail or water-borne fuel is loaded by hand into bunkers, and thence fed automatically into two conveyors, each having a capacity of 40 tons per hour. These distribute the fuel into the storage bunkers over each set of producers. Each bunker holds 40 tons—that is, sufficient to keep the producer working for two days. The gas from the producer is thoroughly washed in mechanical washers, passed through ammonia recovery apparatus, also through the scrubbers and the meters, before being compressed and sent through the mains for distribution.

Since for each ton of coal gasified more than two tons of steam has to be supplied with the blast entering the firegrate of the producer, a considerable amount of steam has to be provided. More than half the total required, however, is obtained from the system of recuperation by circulating the water in the Mond producer plant. The steam for this purpose is raised at a pressure of 120 lb. per square inch, and after passing through the various engines and pumps where it does work, the exhaust is collected and mixed with the air supply to the producers.

It being necessary, for equalizing the station load, to fire with gas alone during part of the day, and to employ coal in addition during the time when the demand for gas is high, the Lancashire boilers employed have been fitted with Bennis "sprinkler" stokers. The gas ducts are led into the top flange of the stoker front and secured by means of a gas-tight joint. The baffle plates, which are situated behind the front, are provided with a passage, the outlet being above the grate; the gas thus passes from the ducts to the furnace. There are two ducts to each flue—that is, four to each boiler—each pair containing a breeches pipe placed immediately behind the hopper and passing thence to the gas supply. This constitutes an extremely simple and satisfactory arrangement.

It being essential that air should have access to the gas, a valve with an adjustable cover is placed on the furnace front to regulate the amount of air supply. The air is conveyed into the furnace through a separate air duct and does not mix with the gas until it reaches the inside of the flue, where ignition takes place.

A test lasting 40 hours with gas firing alone has shown an efficiency of boiler and furnace of 79.1 per cent. Other interesting figures from this test are the following: Steam pressure, 84 lb. per square inch; temperature of steam after superheating, 332 deg. Cent. (630 deg. F.); volume of air supplied per 100 cu. ft. of gas burned, 158.6 cu. ft.; losses to chimney (after passing superheaters and economizers), 11.4 per cent.

The steam from the boilers is led to the various parts of the plant by ring mains, so that each steam-driven machine can be supplied through at least two separate lines. The Lancashire boilers, measuring 9 x 30 ft., are fitted with extended flues. They are also fitted with superheaters, the gases discharging into an economizer containing 4000 sq. ft. of heating surface.

A guarantee was given by the stoker makers that the evaporation of each boiler should not be less than 12,000 lb. of water per hour, with an overload evaporation of 15,000 lb. per hour when desired for short periods. An efficiency of 72 per cent. was also conceded. This has not only been borne out in the tests carried on by the staff of the South Staffordshire Mond Gas Co., but also appreciably exceeded. For instance, an overload evaporation of 17,000 lb. of water per hour from each boiler, instead of 15,000 lb. per hour, was obtained.

Prior to the installation, much inconvenience had been experienced owing to the fact that steam was required to be kept both during the night and from midday Saturday until Monday morning, when it was desirable that labor duties should be at a minimum; but since the introduction of the combined system of firing, the desired flexibility has been attained. A thermal efficiency of 73 per cent. has been secured during a six months' run under all conditions and variations of load, including times when parts of the plant were off for cleaning and inspection. The average quantity of water evaporated per boiler per hour for a month's run was 14,880 lb., during which period the boilers were fired with slack during the day and gas during nights and over week-ends.

Remember that National War Savings Day is June 28. Pledge yourself on or before that day to save to the utmost of your ability and to buy War Savings Stamps that there may be more money, labor and materials to back up those who fight and die for you.

You may not be able to fight, but you can save and buy War Savings Stamps.

Coal Mine Photography—III

By H. A. WILLIAMSON
Fairmont, W. Va.

SYNOPSIS—*It makes little difference so far as photographic reproduction is concerned what style of lettering is employed on a map so long as the lines are sharp and distinct. However, plain letters are preferred to more elaborate designs. The conventional signs used by the United States Geological Survey are excellent for mine maps if augmented by suitable symbols for underground work.*

STYLES of lettering and methods of showing specific features by use of conventional signs vary to such an extent that it would be impractical to attempt to illustrate or classify them in anything less than a book on the subject. There are, however, certain letters and signs which can be used to better advantage than others on map work where this map is intended for photographic reproduction.

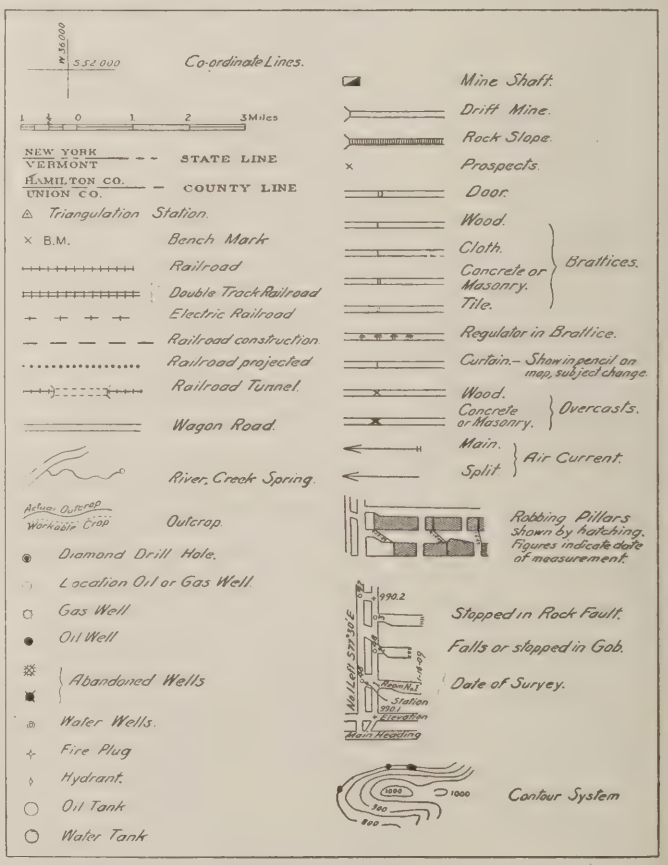
The accompanying illustration is not an attempt to give all or even most of the signs in use, but it does show some of the most common and most suitable for photographic reproduction.

Lettering for photographic work can be almost any style, so long as it is made with clean clear lines. Ornate types are to be avoided. Simple lettering is easier to produce, looks much better, and is more clearly readable after reduction than such styles as Gothic or other complicated forms. The most important single feature on a map for photographic work is probably the scale. The scale shown in the illustration is the one in almost universal use; it makes no difference how much it is enlarged or reduced it is always correct, while any proportional scale is immediately in error on reduction or enlargement.

Proper Indication of Points of Compass

Another item of importance is the indication of the points of the compass. If coördinate lines can be used, and especially if the top of the map can be made the north, it is a far better way than using a north point and having every map laid out with the north direction different. Further, if the latitude or longitude, or both, can be placed on a map it is an advantage as, for example, it allows the location of large scale, small area maps on small scale, large area maps in order to get location of particular points with relation to railroads or other features.

For photographic map work there are no better signs and letters than the standards of the United States Geological Survey. Sheets of these can be obtained from "The Director," United States Geological Survey, Washington, D. C., at 10c. each. However, they do not show underground features, nor various special features, and it becomes necessary to adopt standards to fit the needs of the particular kind of work carried on.



Both in lettering and in signs it is only necessary to remember that simple designs and sharp lines photograph to best advantage, and, as stated in a previous article, a minimum size of letter of $\frac{1}{10}$ in. high is a good standard for five-time reduction.

Where it is necessary to show various features in color, political features are usually black, hypsography brown, hydrography blue, timber areas are tinted over with light, transparent green, triangulation and other surveys either in black or red.

It might be well to mention here the matter of erasures or corrections to maps. It is frequently the case that errors are made or changes desired requiring a large amount of erasing. This is often tiresome and dangerous, particularly on tracing cloth. Much of this work can be avoided by simply leaving the incorrect parts on the map and later opaquing them off the photographic plate.

For the benefit of those draftsmen, with some knowledge of photography, who may desire to carry on photographic map work, I give below a standard method of development, intensification and reduction, and opaquing, together with a note on the rapid drying of glass negatives. (With the exception of the drying process all of this will answer equally as well for the various types of film.)

Presuming that the desired exposure on a suitable plate (with screen if necessary) has been made, we are in a position to start work in the darkroom. Following is the developing formula given in the first article of this series, but here repeated with additional

SCALE IN ALMOST UNIVERSAL USE WHICH MAY BE ENLARGED OR REDUCED WITHOUT ERROR

notes: Water, 15 oz.; sodium carbonate, crystals, ½ oz.; sodium sulphite, crystals, 1 oz.; potassium bromide, crystals, 15 grains. This will keep indefinitely, can be made up in quantities and called a "stock solution."

To develop contrast, or commercial, plates, also tri- or panchromatic plates, for linework: Use the foregoing solution full strength, adding three grains of dry pyrogallic acid for each ounce of solution just when ready to immerse the plate.

To develop out-of-door exposures (or flashlights), roll film and miscellaneous copy work where it is desired to show detail: Use one part of the foregoing solution and two parts water, adding two grains of pyrogallic acid for each ounce of "ready-to-use" solution.

To develop advertising lantern slides: Use one part of stock solution and three parts of water, adding two grains of pyro per ounce of "ready-to-use" solution.

The temperature should be 70 deg. F. Density comes slowly, but the negative should be fully developed in two to five minutes. When developed immerse in: Water, 16 oz.; citric acid, 30 grains, for 30 seconds, and then fix in standard acid fixing bath.

If after fixation and washing the plate should be somewhat under or over exposed, the following method is probably the best now known for reduction or intensification of linework negatives. First be sure the plate is thoroughly washed.

Solution Removes Veiling of Lines

To reduce or remove any veiling of lines use the following solution: One-half dram 10 per cent. solution potassium ferricyanide; 2 oz. hyposulphite soda; 10 oz. water.

This preparation can be used locally or all over the plate. If it is simply desired to reduce an over-exposed plate, the foregoing bath, followed by thorough washing, is all that is necessary.

If the plate is weak, after removing any veiling of lines with the solution given above, wash at least 15 min. in running water and use the following intensifier (Monckhoven's formula). First, bleach through to the back in a solution of mercury chloride, 100 grains; potassium bromide, 100 grains; water 20 oz. When bleached wash 15 min., then darken in the following:

Dissolve 100 grains silver nitrate in 10 oz. distilled water. In another 10 oz. of distilled water dissolve 150 grains potassium cyanide; add silver solution to this in small amounts until the point is reached where the curdy precipitate, which forms as the silver is added and at first disappears completely, does not redissolve. Flow this over the plate, but remove the negative from this solution and wash promptly as soon as the plate is darkened through to the glass side. Too long a time in this will reduce the negative. (The foregoing solutions can be used repeatedly.)

Frequently pinholes or air bells will occur on negatives, and also it is often desirable to cut out some part of a map without actually erasing it from the original. After the negative is thoroughly dry these undesired parts may be blocked out of the negative with opaque. For this work a simple retouching stand may be purchased, or a hole, of suitable size, can be cut in a box, a light placed within the box and the plate placed over the opening. It is a simple matter to block out the undesired parts, using "Alvords" opaque and a medium sized camel's hair color brush. The opaque should be worked as thick as can be conveniently handled and allowed to dry thoroughly before the negative is used.

It is sometimes important to obtain final prints from negatives within a brief time. By having a fresh and strong fixing bath, the negative is fixed in about 3 or 4 min. Remove the plate from the fixing bath and rinse; place the plate in a tray which will just accommodate it, cover with water to half the depth of the tray and add 6 grains of potassium percarbonate for the equivalent of every 4 x 5-in. plate (rock tray)—remove negative when liquid ceases effervescing and wash 3 to 5 min. in running water, then place in bath of wood alcohol for 1 or 2 min.; remove from this and place before an electric fan or in a draft. The plate will dry rapidly by this method. If the fan is just in front of a heater, so that warm air is drawn through onto the plate, the drying will be still more rapid.

Prints can be made with ordinary blueprint paper; or if higher grade work is desired any of the ordinary photographic papers can be used. There is also on the market an excellent photographic cloth which is specially desirable for map work in connection with reports and other data that are desired in lasting form.

Lump Coal for Locomotive Service

Until recently nearly all coal used on locomotives was mine-run—the entire unscreened product of the mines. In the past few years, however, increasing quantities of screened lump coal have been used in locomotive service. This increase in the consumption of lump coal has been due partly to the belief that lump coal, when burned on a locomotive, produces enough more steam than mine-run coal to compensate for its greater cost. Special considerations, such as the desire to lessen the amount of smoke formed, have also led in some instances to the use of lump coal, which is generally believed to require less skill in firing than mine-run coal. The introduction of the mechanical stokers for locomotives has resulted in the use of increasing amounts of various sizes of screenings. Thus far there has been little use of such sizes as egg, egg-run, and nut coal on locomotives, although traffic and market conditions occasionally make it feasible and desirable to use them.

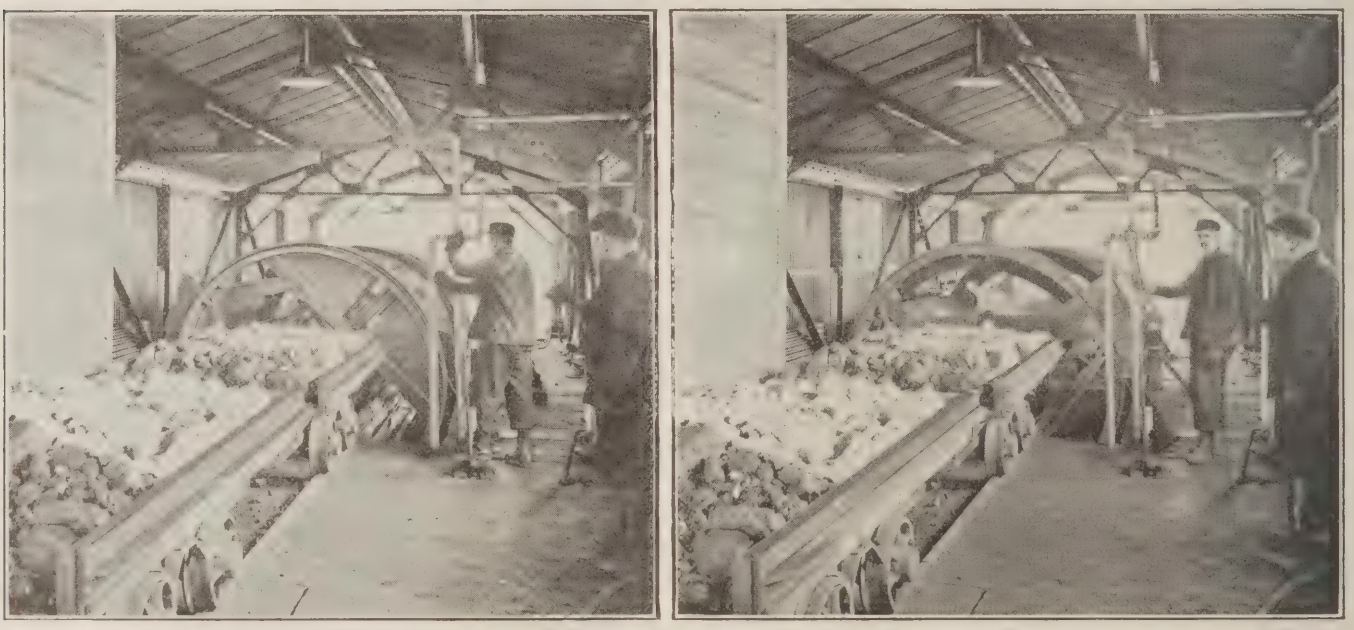
The relative values of several sizes of coal for locomotive use have not been well understood since most laboratory and road tests have been made with mine-run or occasionally with lump coal, and the data are inadequate and conflicting.

A series of tests to determine the value of different sizes of coal has been conducted by the Engineering Experiment Station of the University of Illinois under a coöperative agreement with the International Railway Fuel Association and the United States Bureau of Mines. A Mikado locomotive weighing 142 tons belonging to the Baltimore & Ohio R.R. was used, the tests being made in the locomotive laboratory at Urbana. The results are published in Bulletin No. 101 entitled "Comparative Tests of Six Sizes of Illinois Coal on a Mikado Locomotive," by E. C. Schmidt, J. M. Snodgrass and O. S. Beyer, Jr. Copies may be had without charge by addressing the Engineering Experiment Station, Urbana, Illinois.

Hoisting Coal in Skips*

By JOHN A. GARCIA
Allen & Garcia Co., Engineers, Chicago, Ill.

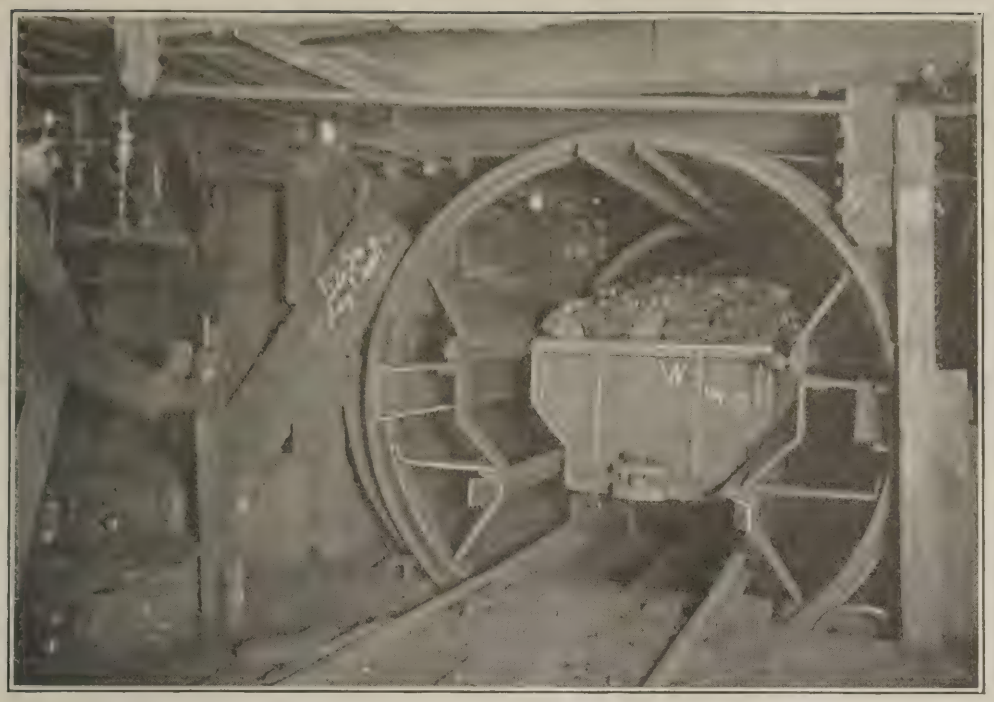
IT IS somewhat remarkable that with the wonderful progress in mechanical and electrical engineering at coal mines in the last ten years or so, and improvements made in methods of mining, the two main contributing causes for most of the troubles in operation have not only been neglected, but deliberately aggravated—that is, low percentage of extraction and vicious speed in caging and hoisting.



In the Middle Western coal fields, excepting, of course, the longwall mines, the extraction is no better today than it was a generation ago; and in southern Illinois several of the most modern mines were recently found to have made an extraction of only 48 per cent. over a period of about six years. Such extraction leads to sealed-off gas areas, squeezes, short life, long haul and difficulties in operation too numerous to mention; and the solution of the problem is worthy of the best efforts of the best men in the industry. However, this is outside the province of this discussion.

The second major problem—speed reduction—involves, of course, maintenance of existing output or opportunity to increase capacity, as there never was a mine where the output was satisfactory, the boss, like Oliver Twist, always asking for more. However, it is impossible in an existing mine to decrease caging time and rope speed without decreasing output, unless the weight of coal per hoist is increased, which apparently can be done only by enlarging the pit car; and this is often impossible. But even when it can be done, the size of the car cannot be increased enough to materially affect the speed of the hoist, and this fact leads to the question of skip hoisting.

The self-dumping cage has been developed from a crude mechanical freak into a device or machine worthy of admiration, and almost respect. Traveling, in some instances, at the rate of 4800 ft. per minute along vertical slides several hundred feet long, dumping a pit car without manual assistance, reseating and dropping back down the shaft at terrific velocity, to be retarded and reset on the sump logs without breakage, often three to four times a minute, eight hours a day, every working day in the year—these are conditions no engineer or designer could meet. The self-dumping cage of today is therefore the product of hard experience, the result of years of persistent and stubborn effort to perfect, strengthen the weak points as they developed, and to adapt it to the constantly increasing demands.



When the cage was first invented, 1000 tons per day was a fair output, and there was every reason for using it as against the stationary platform; but custom and habit in coal mining dies hard, and it was many years after the first self-dumping cages were used before they were in general use. Even today, with our intensive production, we quite often find a mine equipped with a fixed cage, though probably no new mines have been developed in recent years having this type. From 1000 tons we graduated into 2000, and the cage was developed to match the output. Suddenly the capacity of newer mines jumped to 3000 tons, and the hoisting problem became quite serious; the cage began to take on lines of mechanical design, the safety catches offered fair field for the inventors' talent, the automatic stop and caging machine came into service and the construction of mine cars to meet the rough usage and constant dumping shocks became an important feature of mine shopwork.

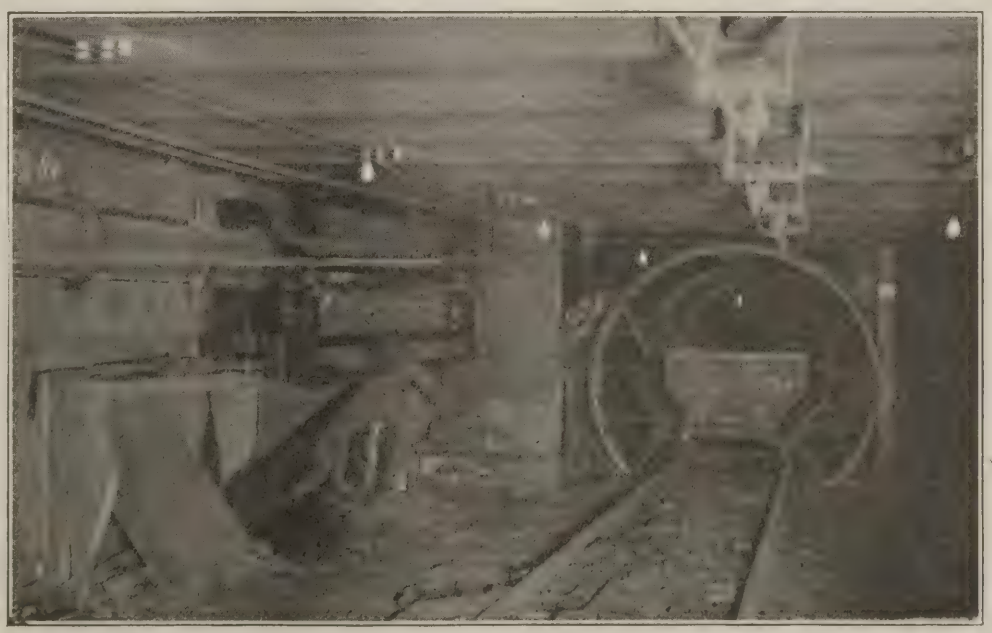
From 3000 tons the ambitious and progressive operator pushed on to 4000, and the mechanics of hoisting became a science. In the last three years we have

DUMPING CARS AT GRANVILLE TIPPLE WITHOUT UNCOUPLING

*Paper read before the Peoria meeting of the Illinois Mining Institute, May 23, 1918.

ROTARY DUMP WITH CARS IN POSITION FOR DUMPING

come to realize the 5000-ton-per-day mine, and the end is not in sight. Recently the mine of the American Coal Mining Co. at Bicknell, Ind., took the world's hoisting record for a single-car, self-dumping cage, producing 5911 tons in a little less than eight hours, using four-ton pit cars and with a total lift of about 360 ft. That means a rope speed of 3100 ft. per minute, caging cars often at the rate of four per minute and an average of over three per minute all day long.



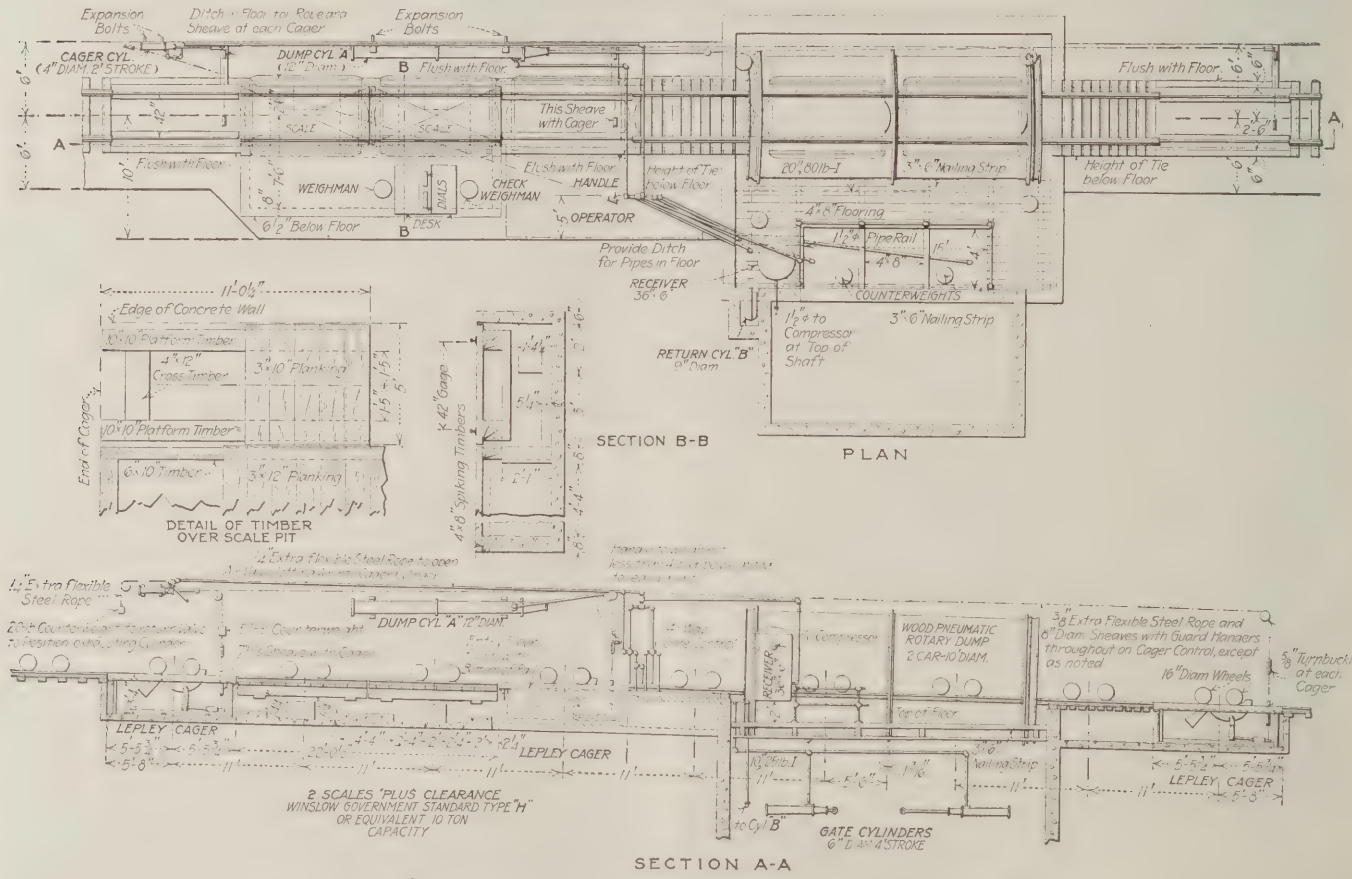
It may be safely assumed that coal mining has not reached such an advanced state of development temporarily, and that the hoisting problem is going to be confined to a few "freak" mines, or to isolated districts.

The march of progress and the keen competition in normal times forces maximum output for minimum investment, and under modern conditions the cost of building and developing a new mine is so high that large capacity is the only way to realize, in a reasonable period of time, on the investment.

However, it is not only dangerous to life and limb and destructive to valuable property to maintain such excessive speeds in production, but it is bad business policy to operate on a schedule that requires every man in the organization to be constantly straining for what is considered a normal output or to put the machinery of a plant constantly and continuously to the breaking test. There surely was some method whereby shaft hoisting could be brought down to the safe and sane plan that well-organized factories with intensive production operate on, and to this end the engineers of the Allen & Garcia Co. began a study of the problem about five years ago.

The first result of this campaign was a self-dumping cage designed to eliminate shock, to prevent overturning in the shaft and to operate at the dumping point without consuming, at that place, 25 per cent. of the total power required for a cycle, as is necessary in the ordinary cage. This result was obtained after four installations had been made, and the mine at Bicknell referred to above was equipped with this type of cage. That mine, however, was built for 3000 tons, and when the development work underground went on beyond the designed capacity of the shaft and hoist, they simply speeded up all along the line until they reached the extreme limit of almost 6000 tons and an average of over 5000. It then became apparent that the engineers must make the hoisting capacity so great that there would be no possibility of mining and hauling a tonnage that would require excessive rope speeds, and the only practical answer was the skip; so a thorough investigation of skip design was made and data accumulated on the few installations made in this country.

The information secured on existing installations in this section was disappointing. None were found that were satisfactory, and mining men everywhere were inclined to condemn the system as impractical. Each case was analyzed and studied carefully, and in the end it was found that there was something radically



ROTARY DUMP AND FIXTURES AT SHAFT BOTTOM

wrong with each installation in both general design and in details of construction.

The nearest approach to a success was at the eigler mine, and here the hoisting feature of the problem had been solved; but the dumping, both at top and bottom, condemned the whole design. At this mine drop-bottom cars were used, the coal dumped direct into a deep pit holding about 50 tons, and from this pit, or underground bin, the coal flowed through a gate, operated by a compressed-air ram, into the skip, which held approximately eight tons. The drop-bottom cars caused endless trouble, the fall of the coal from cars to bin and bin to skip, together with grinding and crushing in the pit itself, smashed the lumps and greatly increased the percentage of screenings. The outlet gates in the bin were under test, four dumps of two cars each per minute, or 32 tons per minute, which means a theoretical capacity of over 15,000 tons per day. If the mine ever reaches even half that tonnage, there will be no need of "speeding her up" as far as dumping the pit cars is concerned.

In order to eliminate the bin with resultant breakage, the designs for new mines were worked out to place the dump along the side of the shaft, the center line of the dump being parallel with the plane of the two hoisting ropes and far enough back so that the coal could flow to either skip over a steel-lined chute, avoiding all drop excepting the fall from the end of the chute into the skip. The coal is diverted to either skip by means of a movable plate or traveling vane, pivoted at

DETAILS OF UNDERGROUND ROTARY DUMP, SCALES AND OTHER EQUIPMENT

80 to 40 ft. down below the mine rails where the dust and darkness prevented the operator from seeing the skip while loading, with resultant part loads or overloading. The skips discharged in the tipple into a large bin holding about 50 tons, where the breakage was further increased.

In searching for a dump that would meet all the requirements of a coal mine, the pneumatic rotary dump invented by A. H. Wood, and installed at his mine at Kildav, Harlan County, Kentucky, was discovered. After most careful examination and analysis of design by independent engineers, it was pronounced satisfactory, and Mr. Wood was awarded a contract to install a two-car dump in the Zeigler mine. The outfit was put into service in December, 1916, and has been in operation continuously ever since with no troubles of any kind, and is capable of dumping the maximum tonnage the mine can make—in fact, its capacity is, the mid-bunton and pulled by a ⅝-in. cable across the flow chute to either end of the dump carriage. The design provides that the vane will automatically take the proper end of the carriage so that the coal will always flow into a landed skip and not into the sump.

Provision has been made for controlling the dump so that, if desired, the dump cannot rotate unless a skip is in place; on some installations cut-off gates at the end of the chutes are constructed to avoid leakage of small coal into the sump. These gates are opened by the descending skip and closed when the skip is hoisted, by a small counterweight.

The pneumatic rotary dump is a simple affair. The carriage is made of ordinary railroad iron bent to a true circle, and the several circles are fastened together with channels or other standard sections. These circles rest on trunnions similar to ordinary roller-bearing pit-car wheels; common sheet iron forms the shield that

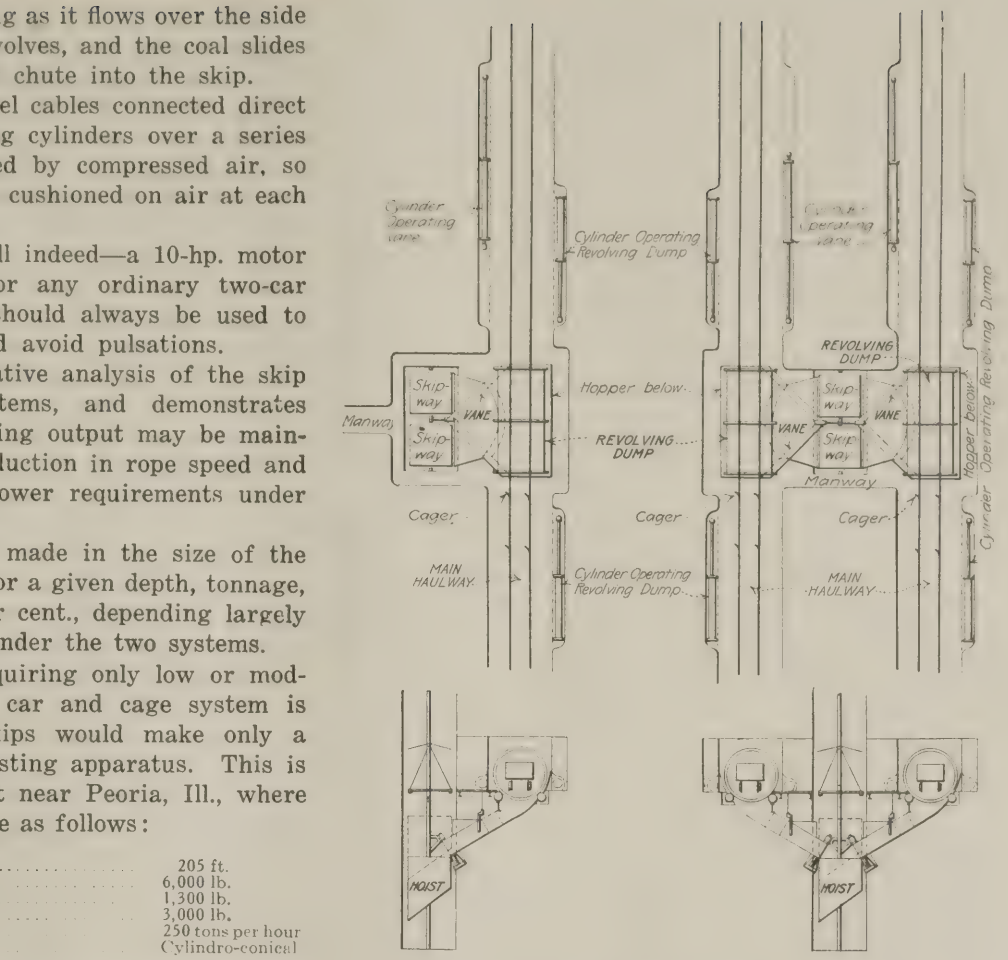
prevents the coal from dropping as it flows over the side of the car as the carriage revolves, and the coal slides along the shield over the flow chute into the skip.

The dump is rotated by steel cables connected direct to the piston rods of two long cylinders over a series of small sheaves and operated by compressed air, so that the shock of the dump is cushioned on air at each revolution.

The power required is small indeed—a 10-hp. motor will furnish ample power for any ordinary two-car dump, but a small receiver should always be used to provide constant pressure and avoid pulsations.

The following is a comparative analysis of the skip and self-dumping cage systems, and demonstrates clearly the fact that an existing output may be maintained with a 40 per cent. reduction in rope speed and a material saving made in power requirements under certain conditions.

The reduction that can be made in the size of the hoisting equipment required for a given depth, tonnage, etc., varies from 10 to 70 per cent., depending largely on the rope speeds required under the two systems.



For hoisting conditions requiring only low or moderate rope speeds when the car and cage system is used, the substitution of skips would make only a little difference in size of hoisting apparatus. This is shown by the case of a shaft near Peoria, Ill., where the hoisting requirements were as follows:

Distance rail to dump	205 ft.
Weight of cage	6,000 lb.
Weight of car	1,300 lb.
Weight of coal per car	3,000 lb.
Capacity	250 tons per hour
Drum	Cylindro-conical

On the basis of an electric hoist the root mean square is 166 hp. (R.M.S.[1] = calculation of horsepower on heating basis). On the basis of an electric hoist and skips holding two cars, the R.M.S. is 162 horsepower.

On the basis of an electric hoist and skips holding four cars, the R.M.S. is 148 hp. In this case the average rope speed with the car and cage system is only 800 ft. per minute, and an increase in load carried and a reduction in rope speed makes little difference in either size of equipment or power consumption. In the foregoing case the power consumption is reduced from 0.505 to 0.504 kw.-hr. per ton.

[1]R. M. S. = the square root of the average value squared. Or it is equivalent to the continuous load (in horsepower) that would have the same heating effect on the motor as the fluctuating horsepower under consideration.

SINGLE AND DOUBLE ROTARY DUMPS

On the basis of a mine capacity of 4000 tons in six hours with the following:

Weight of car	3,000 lb.
Weight of cage	8,000 lb.
Weight of coal	8,000 lb.
Distance rail to dump	300 ft.

the R.M.S. is 671 hp., while, by using a skip hoisting eight tons, the horsepower would be reduced to 580. The rope speed is reduced from 24.8 to 15.6 ft. per second.

Recently an operator desired to electrify the hoist

TRACK ARRANGEMENT AT TOP OF GRANVILLE TIPPLE

in connection with a shaft near Springfield, Ill. The duty given was as follows:

Depth of shaft	250 ft.
Weight of cage	5,000 lb.
Weight of car	1,500 lb.
Weight of coal per car	4,000 lb.
Type of drum	Cylindro-conical
Time of cycle	16.5 sec.

This required a maximum rope speed of 35 ft. per sec. and a motor 700 hp. in size. In addition, in order to get safe and economical hoisting, it was deemed necessary to install the Ward Leonard system of electrical control.

By the installation of skips at this mine it would have been possible to secure the tonnage of 432 tons an hour with a 500-hp. motor; an induction-type motor could have been used, which at the present time would mean a reduction in cost of approximately $18,000.

At one of the Franklin County mines now equipped with a 1150-hp. hoist motor, the question of increasing the tonnage by 20 per cent. was recently discussed. To make this increase, retaining the cage and car system, required the installation of a 3000-hp. motor with forced ventilation, which is equivalent to about 4000 hp. with natural ventilation. The duty on which this was based is as follows:

Total hoist	667 ft.
Weight of cage	15,000 lb.
Weight of car	3,300 lb.
Weight of coal	10,000 lb.
Type of drum	Cylindro-conical
Maximum rope speed	4,375 ft. per min.
Number of trips in 7 hours	1,200

This increase in tonnage could be made by the installation of a 10-ton skip with a 1250-hp. motor. It is evident, therefore, that increasing the rope speed in cage hoisting, to obtain a fixed tonnage, means decreased size of hoisting equipment on the basis of skip hoisting for the same tonnage. The preceding examples are given on the basis of actual conditions which have come up in this field.

The actual results as obtained at the Granville colliery near DuBois, Penn., a recent installation, on caging and time of dumping, is given in the following dumping test:

TIME OF DUMPING A TRIP OF 20 LOADED CARS

In the Wood Equipment Co. two-car rotary dump, using swivel hitchings

	Time of Trip Travel, in Seconds	Time of Dumping (Two Cars), in Seconds		Time of Trip Travel, in Seconds	Time of Dumping (Two Cars) in Seconds
1st move	20	7	7th move	15	7
2d move	15	7	8th move	13	7
3d move	15	7	9th move	13	7
4th move	15	7	10th move	17	7
5th move	15	7			
6th move	12	7	Total	148	70

A total of 20 cars was dumped in 218 sec., or an average of one car every 11 sec., which would give 5½ cars per minute.

By using four-ton cars the capacity would be 22 tons per minute, or 1320 tons per hour, or 10,560 tons per day of eight hours. This test was made when the plant had been operating only a few weeks, before the "new" had worn off, and before the men were thoroughly familiar with the operation, but it gives a good idea of capacity.

Another recent installation at the two mines of the Columbus Mining Co., near Hazard, Ky., where the dumps were placed at the tram tracks of drift tipples, verified the tests made at the Granville and Zeigler collieries, so it is safe to say that the dumping part of the skip hoisting problem has been solved.

Placing the loaded cars in the dump is a rather simple matter. They are handled on the mine bottom practically the same as if cages were used, excepting that two, or if desired three, cars at a time are caged instead of one, and the horns of the caging machines are spaced accordingly.

It was found by using swivel hitchings and spacing the track horns properly, that it was not necessary to uncouple the trip when passing the cars through the dump, and the Granville and Hazard mines are so equipped—trips of 25 and 30 cars passing over the scale, through the blocks and dump and out to the empty track—one spragger and one man at the dump handling the entire trip.

In the tipple the coal flows out of the skip as it turns over through the long radius curves and slides

TIPPLE AT ZEIGLER MINE

down a chute to a slow-moving apron feeder, where it is discharged at a uniform rate on the screens. Every effort has been made to avoid all drop or fall to the coal, the only real drop being from the chute into the skip, all other coal movement being slide rather than drop. The fall of the coal from chute to skip compares with the throwing of the coal from the pit car to the weigh basket in the cage system, and it is confidently expected that the total breakage under the new system will be no more than with a cage.

There is another great advantage to the skip hoist that becomes apparent after the system has been in service, and that is the solid-end pit car. Doors on mine cars are a source of continual maintenance expense, they are difficult to keep in good order and there is quite a saving in first cost of cars when doors are eliminated. The solid-end car also makes for cleaner

roads, as most of the coal dust on haulage roads is from leaks between car bottom or sides and the door; the solid car can be built practically dustproof, the only spill being lumps brushed or bumped off the top, and these are comparatively easy to handle.

No data are submitted on comparative first costs of the two systems because none of the installations now under way have been completed, but as near as can be determined from costs to date there will be little saving in first cost of the skip method as against the cage. The cost of the dump itself is probably balanced in saving on pit-car construction, but skips cost more than cages at present prices of plate and the construction of the chutes from dump to skip, with the additional shaft depth required, increases cost of skip installation.

In the tipple structure it is not necessary to build the weigh-house, or that section of the structure carrying the scales, since the coal is all weighed on the bottom before dumping. There is a real saving effected here—probably enough to balance the cost of the extra sump and flow chutes.

The Allen & Garcia Co. is engineering four new skip-installation jobs: The Toluca Coal Co. mine at Toluca, Ill.; the Kathleen mine near Duquoin, Ill., for the Union Colliery Co.; the Valier mine, north of Christopher, Ill., for the Chicago, Burlington & Quincy R.R., and the new mine of the Buckeye Coal Co., at Nemacolin, Penn. At each of these mines, excepting Toluca, the refuse rock, men and material will be handled via a separate compartment at the air shaft; but at Toluca the skip is equipped with an adjustable platform for raising and lowering men. The rock is to be handled in the skips just the same as coal, but diverted by a flop gate in the dump chute in the tipple to the rock bin.

The separate man and material hoist is practically a necessity at large-tonnage mines and is an asset to almost any mine. At the Kathleen and Valier mines practically all the buildings are located with reference to the air and escape shafts, and the only building at the main shaft is the small structure housing the hoisting engines. It is expected to have three shifts of engineers at the man and material hoist and only one at the main engine, since this latter equipment will be in service only during the eight-hour shift when hoisting coal.

For small mines, skip hoisting has the same attractive features as for large producers, where it is or soon will be a necessity, and there are numerous advantages not referred to herein, due to the elimination of the self-dumping cage and open end pit car.

The advocates of skip hoisting at coal mines probably have rough sledding ahead, as the coal man is conservative, to say the least, and skeptical about radical changes in established conditions or customs. Nevertheless, it seems wise that the question be given serious study and consideration. In the last year some of the most competent and thoughtful men in the coal-mining industry have become converts to skip hoisting, and some of them are spending large sums of their own money to demonstrate the courage of their convictions. Let us wish them complete success. If we can help in any way to better the conditions of the industry, make mining safer, or improve our methods, it is not only our duty to do so, but our pleasure as well.

Certificate of Merit for Coal Meter

The Franklin Institute has recently awarded its Certificate of Merit to Oliver D. Havard, of Allentown, Penn., for the Havard coal meter. This is a device which is fixed in the feeding pipe to a furnace, for the purpose of measuring the coal used. The coal is usually crushed to a certain degree of fineness and, in passing through the pipe, rotates a vane connected with a recording device, which is so calibrated that the rotations of the index will indicate the amount of coal passing through the pipe. This is of especial value in connection with automatic devices for feeding furnaces.

April Production in British Columbia

A statement of tonnage of coal mined by the various British Columbia collieries for the month of April, 1918, issued by the Department of Mines, gives a total of 224,992 tons. The tonnages from the different districts follow:

	Tons
Vancouver Island	148,098
Crows Nest Pass	62,641
Nicola-Princeton	14,253
Total	224,992

The total tonnage produced in the Province for the first four months of this year is 898,036 tons. For the same period in 1917 there were 820,864 tons produced, making an increase for the same period this year of 77,272 tons. Coal produced in the coal mines of British Columbia for April follows:

Company	Production, Tons
Crow's Nest Pass Coal Co., Coal Creek	37,975
Crow's Nest Pass Coal Co., Michel, B. C.	17,280
Corbin Coal and Coke Co., Corbin	7,386
Middlesboro Collieries, Ltd., Merritt	8,939
Fleming Coal Co., Merritt	2,806
Princeton Coal and Land Co., Princeton	2,508
Canadian Western Fuel Co., Nanaimo, B. C.	66,025
Canadian Collieries (D), Ltd., Cumberland, B. C.	50,531
Canadian Collieries (D), Ltd., Extension, B. C.	19,971
Pacific Coast Coal Mines, Ltd., South Wellington	9,325
Nanoose Collieries Co., Nanoose Bay, B. C.	2,246
Total production	224,992

It is thus shown that the production continues to climb, and the indications are that it will go much higher before the end of the year. The Granby Consolidated Mining and Smelting Co., having opened up a 14-ft. seam on one of the three slopes being driven on its coal land holdings on Vancouver Island, may be expected to bring to the surface at least 500 tons a day before long. The new No. 5 Mines of the Canadian Collieries (D), Ltd., at South Wellington, which is producing between 20 and 30 tons a day on development, will run between 500 and 600 tons per diem before the end of the year. Incidentally, it may be said that the company is installing a complete plant at this mine. The tipple arrangements now are being completed, screening equipment prepared and yards laid out. The Morden mine of the Pacific Coast Collieries, which was in barren ground recently, has struck an 11-ft. seam and will be doing better from this time forward, while the Harewood Mine, of the Canadian Western Fuel Co., Nanaimo, B. C., is proving one of the most remarkable single mines of the Island. After being abandoned it was reopened last fall, and during the month of April produced at the rate of about 800 tons a day.

Blower Fans in Gangway Driving

By WILBUR L. CROSS
Ashland, Penn.

SYNOPSIS—*In certain portions of the anthracite field the use of small blower fans and wooden pipe for the conveyance of air to the face shows many advantages over other methods of driving-gangway ventilation. Supplanting a fanboy with a motor pays for itself in about two months.*

IN THE southern anthracite field where, because of the steep pitching and small beds, penetration of old workings and the frequent impossibility of having other than small airways near some of the working faces the question of auxiliary ventilation becomes a serious problem, every effort has to be made to solve the numerous difficulties presented by different phases of the work. One of these, the ventilation of driving gangways, offers a problem which hitherto has not been satisfactorily solved.

Some of the methods most commonly used to ventilate the driving gangways may be briefly described as follows:

1. By Means of a Door in the Gangway. A temporary door is built in the gangway just outside of the last chute. From this a square wooden box or pipe is extended nearly to the face. This carries the air to the face being driven ahead of the last chute. Under this system the door and the pipe must be moved ahead as the gangway is extended. This is a slow and expensive process especially if a tight door is made.

2. By Means of a Hand Fan Turned by a Fanboy. Under this system a small hand fan is installed connected to a wooden pipe made of 1 x 12-in. plank. A boy by turning the fan by hand keeps the gas away from the face of the gangway and chutes. It is at best a poor method for the force of air is not sufficient to secure good ventilation nor is it possible now to get boys to stay on the job.

3. By Means of a Power-Driven Blower Fan. This system is a development of the fan and fanboy method. The fan most commonly used is a high-speed blower-type fan 12 in. in diameter, direct-connected to a ¼ hp. compound-wound motor, speed 1700 r.p.m. The motor is connected by No. 14 weatherproof copper wire to the nearest trolley feeder and protected by the ordinary type of entrance switch equipped with plug fuses.

The fan is situated outside of the last chute so that fresh air entering the gangway comes to the fan. The air is carried to the face of the gangway and chutes through a 6-in. inside diameter wood pipe. This is the ordinary wood pipe used for water supply. A strong pipe is needed for this service, one which will withstand hard knocks, rough handling, small coal and rock falls from the chutes and cars and pieces blown from the face.

In some places sheet steel or canvas pipe may be used to advantage, but for all-around use in the gangways driven in the steep pitching beds the wood pipe on account of its ability to withstand rough handling and hard service has been found to give the best satisfaction. Wood pipe as ordered from the factory will have mortise and tenon joints. It is well to order the pipe mortised for 6-in. wrought-iron pipe and to cut nipples from scrap pipe which will be found around any colliery for making the joints. The reason for this is that the wooden tenon will not stand up under any but the most careful handling, and if broken renders the pipe practically useless. The fan and pipe must of course be moved ahead as the gangway is driven forward. This is a small job which may be performed by the gangway man in an hour on company time or can be done by the repairman.

The following equipment at the prices noted will be all that will be needed for one gangway: One fan and motor complete, $60; 100 ft. of wood pipe at 34c., $34; one wooden tee, $2.50; one wooden 45-deg. elbow, $2.50; one entrance switch and wire, $5—a total of $104.

The equipment costs about what a fanboy would be paid in two months. In other words, at the end of two months the saving in the fanboy's wages will have paid for the equipment. With ordinary care there need be no repairs for five or six months other than the replacement of the brushes. However, due to various causes both avoidable and unavoidable, armatures and field coils will be burned out. A charge of $4 per month for armatures, coils, broken brush springs, fan-blades, etc., will come close to the average if 10 or 15 fans are in service and care is taken to prevent the avoidable causes of burnouts, which will be enumerated later.

The life of the wood pipe with ordinary wear and tear will be at least six years. The motor and fan if kept in repair will also last the same length of time. The accompanying table may accordingly be made up to show the monthly cost of one fan. No charge for labor is included as it is assumed that there is an electrician already in the employ of the company. This man can take care of the few fans needed at the colliery and still keep up the other equipment. From one point of view this is not an accurate way of figuring costs. It is accurate, however, in that it shows what the extra monthly cost of installing these fans would be over and above the cost previous to their installation.

Depreciation of equipment, 1/72 of $104	$1.45
Repairs	4.00
Interest on investment	.52
Power cost, 1,500 watt-hr. per day—25 days per month, at 2c. per kw.-hr	.75
Total	$6.72

For a total cost, then, of $6.72 per month the driving gangways are kept free from gas and the smoke quickly cleared away after a shot. The cost is so small when the great advantages of the installation are taken into account that it can almost be ignored.

To keep the repair costs down to normal and, what is of more importance than cost, to keep the fans always in working order the avoidable causes of burnouts must be known and remedied. Most of the avoidable troubles experienced are due to one or more of the three following conditions:

1. *Ill Treatment or Neglect.* Bearings not oiled or not replaced until they are worn so that the armature rubs the pole pieces. Fuses are blown out and are re-

placed with copper wire. Brushes are not cared for or the commutator is allowed to get dirty.

Miners Attempting To Do Electrical Work. An instance may be cited of a miner who saw a slight sparking at the brushes and poured water on the commutator to "put out the fire." "Me see him little fire, putten on for water. Zip! Big fireworks. Motor she no go."

2. *Dust Collections.* By far the greatest number of burnouts may be traced to an accumulation of dust in the motor. It is almost impossible to completely protect the motor so that dust will not get into it. This dust, if allowed to accumulate, will absorb surplus oil, ignite from sparks from the commutator and burn the insulation from the coils with disastrous results. If the electrician's assistant, whose duty it is to keep these fan motors in order, carries with him a small hand bellows he can keep the dust from accumulating by blowing it out every time he inspects and oils the motors. This little precaution will prevent about 90 per cent. of the burnouts which would otherwise occur.

3. *Poor Voltage.* In some of the sections of the anthracite collieries the trolley feeders are not large enough to carry the necessary amount of current when the locomotives have a hard pull. The locomotive motors are built to withstand a wide range of voltage, but the small fan motors are not. Consequently, the fan motor should be connected to a feeder where the voltage will be fairly constant, otherwise the excess current due to variation in voltage and consequent loss of speed in the fan will quickly break down the insulation and result in burnt-out armatures.

I have specified in this article and given reasons why wood pipe should be used instead of the other classes of pipe which might be employed. It must not be supposed that I am condemning the use of the canvas pipe which has been widely used in the anthracite as well as the bituminous regions, and in tunnel driving. For the special class of work that I have described and for the reasons given I advocate the use of the wood pipe in the manner set forth above. In work where there is little danger of falls and the pipe can be suspended, the canvas tube will be found to be easier to install and more convenient in every way.

Minecdotes

In Which Poor Judgment Is Shown

Recently a serious accident was avoided at a certain colliery through sheer good luck. It was on one of the numerous holidays observed by foreign-born miners, and some of the men did not report for work. However, the mine was operated for a few hours regardless of the absentees.

When the mine foreman learned of the absence of a certain motorman who usually operated one of the gathering locomotives he promptly lost his good nature —provided he ever had any of the genuine article. After relieving his emotions somewhat through the medium of profanity, he instructed a young fellow who was standing nearby awaiting his day's orders to take charge of and operate the locomotive.

Now, this young fellow knew as much about the proper operation of an electric locomotive as does the average bull terrier about aëronautics. This he tried to explain to the irate foreman. But the latter thought the lad was lying. He considered that the young fellow ought, as a matter of course, to know something, at least, about handling a mine motor. The foreman considered the man's protestations of ignorance a subterfuge whereby he hoped to secure a job more to his liking. He therefore cut the young fellow short with the words: "You will either run that motor or go home. There will be no more sneaking out of jobs that you do not like around here." The lad accordingly promised to do his best.

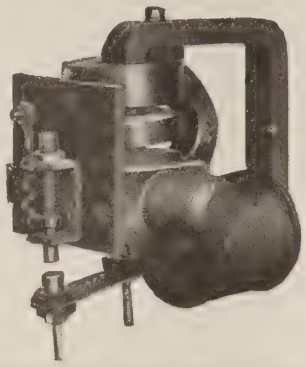
As has been stated, this motorman *pro tem.* knew next to nothing of mine motors and the ways thereof. When he reached the lift where the locomotive was, being ignorant of the fact that the current-switch had to be closed in order to put "juice" in the trolley wire, he took off his coat and stowed it and his dinner bucket carefully away on the locomotive. He instructed the brakeman (who knew no more about the machine than he did) to go ahead and place all the switches for a straight road.

The young man then took his place and started to open the controller. The motor, however, refused to "mote," no matter how far over he threw the lever. Recalling the brakeman, he asked him if he knew what was wrong. But the latter was as much in the dark as the motorman appointee. They were stuck.

Finally, after exhausting their combined electrical knowledge, they started for the telephone to summon the boss, much though they disliked to do so. About 100 ft. from the locomotive they came upon the open switch that caused their difficulties. They threw it to see if anything would happen—and things happened in a hurry.

The controller had been left in the "full on" position, and in the course of the motor's wild flight along the track it tore down seven doors and finally pulverized a car against the face of the gangway where the gangway miner and his laborer would have been had they not been celebrating.

The rest of the miners on that gangway had to go home on account of deranged ventilation. The motorman *pro tem.* was discharged. He now knows more about switches, motors, controllers, and a few other things, than he did before. The boss—well, perhaps he also is somewhat wiser.

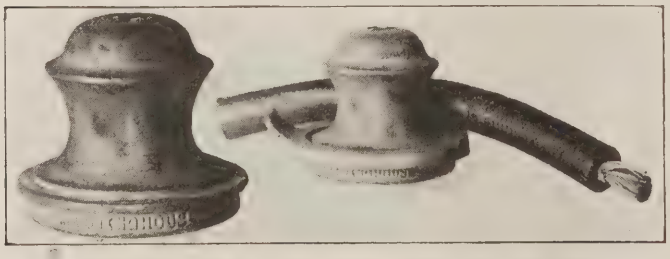


POWER HOUSE AND TIPPLE AT THE WABASH MINE OF THE WESTERN COAL AND MINING CO.

New Apparatus and Equipment

Reverse-Current Relays

A new form of reverse-current relay has been developed and placed on the market by the Automatic Reclosing Circuit Breaker Co. These relays are of the circuit-opening type and are so designed that they will open either upon reversal of current or with zero current at abnormally low voltage. The relay is closed and held closed by a shunt polarizing coil. A high resistance is connected in series with this coil. To close the relay a push-button switch is provided which temporarily short-circuits the high resistance. This high resistance limits the current in the shunt winding to just sufficient value to hold the relay closed. A reversal of current or failure of voltage will thus cause the relay to open.



REVERSE-CURRENT RELAY
100 to 800 ampere size

These relays are designed for mounting on the rear of a circuit-breaker panel. The 1200- and 2000-amp. size has a magnetic yoke which surrounds the upper stud of the breaker. The 400- to 800-amp. size relay is provided with a series winding the terminal of which is connected directly to the upper stud on the rear of the panel.

Armored Corner Insulator for Feeder Cables

A new Pittsburgh-type of corner insulator, for securely holding feeder cables on curves, is being marketed by the Westinghouse Electric and Manufacturing Co. This corner insulator is provided with a special collar, or retaining ring, for use where the curve is slight and the cable likely to slip off an ordinary insulator. The collar has an extended lip which curves up around the cable and keeps it in the groove regardless of the angle at which the cable turns. This eliminates the necessity for tie wires and saves time in erection.

CORNER INSULATOR FOR USE ON CURVES

The collar is free to move on the insulator cap, so that after the insulator is screwed to the pin the collar may be turned until the cable seat is in the position best suited to support the cable. For sharp curves the insulator can be used without this collar, as the deep side groove holds the cable firmly in position.

These insulators are made of molded insulation surrounded by a sherardized malleable-iron cap. They are made with a 1-in. pinhole and are furnished in two sizes for feeders of 500,000 and 1,000,000 circular mils respectively.

The Development of "John Crane" Packing

Seldom has an engineering invention or discovery attracted so much attention and created so much interest among operating engineers as has the well-known "John Crane" flexible metallic packing. This packing was invented by an operating engineer named John Crane in the early spring of 1912. Mr. Crane then had charge of a large power plant and was directly responsible for maintenance and repair costs.

His first object was to develop a permanent packing. From actual experience he knew that soft packings ordinarily lasted only a few months, their life depending upon the condition of the plungers or piston rods. Of course, he desired to reduce the bills and if possible to make his packing permanent. He noticed that where metal and fabric were combined in packings the life of such packing was lengthened; also that metals were not affected by heat or water, while the soft packings were. The metal not only lengthened the life of the packing, but it seemed to polish the plunger. Hence the idea came to him of an all-metallic packing.

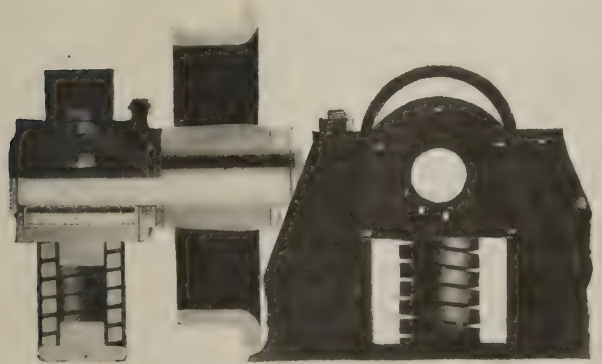
"JOHN CRANE" COMPRESSIBLE PACKING

After much thought and experimentation, John Crane evolved the idea of taking long, thin continuous strips of metal foil and wrapping this spirally round and round, treating each sheet with a layer of lubricant to permit the sheets to slide on each other and to allow bending about the smallest diameter, also giving the product a compressibility sufficient to compensate for wear and sufficient to control any ordinary pressure. These spirally wrapped sheets, he found, formed perfect barriers against high pressure and made a strong, durable construction.

Mr. Crane had packed many stuffing boxes and knew that a packing to be a success must be simple to instal,

one that could be placed in the same stuffing boxes as soft packings and with equal ease. He therefore used soft metal which could be cut with a knife, took any form or shape under pressure of the gland and bent about the plunger easily.

Reduction of rod friction and elimination of wear were also carefully borne in mind when this packing was developed. That is why the inventor selected an anti-friction metallic-sheet combination containing a babbitt alloy. A mechanical combination of these babbitt sheets spirally wound with lubricant between each sheet naturally was successful in greatly reducing the wear on the rod. To date this saving in wear has amounted to many thousands of dollars that would otherwise have been spent for repairs, replacements and labor charges. It does not require an expert to prove that long-lived packing is highly desirable from the investor's standpoint.



"John Crane" products are now made up in many forms of die-pressed, hand-pressed, straight lengths, rings, coil form and spiralled from 1/32 to 2 in. thick, suitable for steam, air, ammonia, hot or cold water, high, low or hydraulic pressure, oil and acid service. The "John Crane" line has been steadily developed and today any combination of metal alloys for special services can be secured, either in the form of a packing or in a gasket.

As shown in the accompanying illustration, this packing is merely smooth babbitt sheets, thoroughly lubricated, wrapped spirally, forming an all-metallic, flexible, compressible, simple and lasting product for the purpose intended. Rings are generally preferred for large plungers, whereas coils are used in smaller work as in valves, traps and small steam rods.

Improvement in Roller Bearing Journal Boxes

The coal-mining industry has not had a marked change in the method of applying roller bearings to mine cars for a long time. The usual method of application is to install the anti-friction bearings in the hubs of the wheels.

The Fleming self-aligning journal box equipped with

FLEMING JOURNAL BOX WITH HYATT ROLLER BEARINGS.

Hyatt roller bearings, as shown in the accompanying illustration, is a distinct departure from the old method, in that it presents several novel features for the application of this type of bearings to mine cars, especially those carrying from three to five tons of coal. They are furnished with heat-treated axles. This secures a durable equipment, since such axles wear for a long term of years and the danger of their being bent or broken is almost entirely eliminated. Heat-treated axles are coming more and more into use on mine cars and the day is approaching when every modern mine car will operate upon such axles.

The illustration shows a box of the type used with inside wheels, but the boxes are also furnished for use with outside wheels, the fundamental principles remaining the same, a slight change being made in the end plates. These boxes are manufactured by the J. R. Fleming & Son Co., Inc., of Scranton, Penn., and can be applied to both anthracite and bituminous mine cars.

Legal Department

Liability of Mine Operators

By Chesla C. Sherlock,
Attorney at Law, Des Moines, Iowa

The liability of mine operators for the acts of fellow servants has called for no small degree of consideration from the courts. Under the common law, the master was not liable for the negligent acts of a fellow servant. This was a defense recognized by the law and one that mine operators were permitted to use whenever the opportunity presented itself.

The time came, however, when the public saw that the ordinary defenses allowed employers under the common law were not only sadly out of date, but wholly inadequate and unjust to the workmen. Several of the states, moved by this growing popular feeling, passed the so-called mining acts which either abrogated, or modified to a considerable extent, the common law defenses of the employers.

These acts generally provide that mine operators shall not be relieved from liability for injury to a workman on the ground that he was injured by the negligence of a fellow servant. Naturally, the question has come up, What is mining and when will the acts apply?

In a Missouri case, it appeared that the injured workman had been engaged to sink a shaft for the discovery of coal. In the course of his employment he received an injury and brought suit, the employer defending on the ground that his injury was due to the negligence of a fellow servant, and that exploring for coal was not "mining" within the meaning of the Missouri statute.

The court went into the question very thoroughly, but held that "persons employed to sink a prospect hole for the discovery of coal are not within a statute rendering the owners or operators of mines producing coal or other valuable minerals liable for injuries to their employees caused by the negligence of fellow servants."

The Oklahoma constitution expressly abrogates the fellow servant rule in that state in respect to certain specified employments, which includes that of mining operations.

The courts were called upon to determine whether or not drilling a well to search for oil or gas was a mining operation.

A case came up where it appeared that a drill was being operated by two men, one of whom was known as a driller and the other as a tool dresser, the drill being run by an engine. Plaintiff, the tool dresser, while operating the engine, raised the stem into the derrick preparatory to taking it down, a rope having been tied around it by the driller before it was raised, and finding he had not raised the stem high enough to clear the girder, plaintiff went up into the derrick, when the driller called to him to take it out under the girder. Plaintiff then walked out on a walking beam where he could not support himself against the timbers of the derrick, and as he pulled down and outward on the rope, it came untied, and he lost his balance, fell to the ground and was injured. The negligence alleged was that of the driller in tying the rope so that it could come untied. The defense was that plaintiff and driller were fellow servants and defendants were not liable. The plaintiff then claimed that the work he was doing was mining and that the fellow servant rule was abrogated in such work.

However, the court held that "drilling a well in search of oil or gas is not mining within the meaning of the constitution," and that the common law rule of fellow servant governed the case.

The Missouri statute, passed in 1909, reads as follows: "Every person, company or corporation operating a mine or mines in this state producing lead, zinc, coal or other valuable minerals, shall be liable for all damages sustained by any agent or servant thereof while engaged in operating such mine or mines, by reason of the negligence of any other agent or servant thereof: Provided, that it may be shown in defense that the person injured was guilty of negligence contributing as a proximate cause to produce the injury."

In a Missouri case, it appeared that the plaintiff was a driver in a coal mine operated by the defendant. On the occasion of his injury, he had taken empty cars to the end of the track and piled them up on the sides of the track to make way for a loaded train he had to get out. Another driver came along and piled more cars up, but left one in such a way as to project over the track. The plaintiff ran into the obstruction, being unable to see it in the dim light, and crushed his right leg and foot.

The court held that the defendant was liable under the above section of the statute and affirmed the judgment in favor of the plaintiff.

The courts of Missouri have further said that a master is liable to a servant for the negligence of a fellow servant, under the Missouri statute, without any exception save that of contributory negligence.

Under the Montana statute, a mine owner is liable for any damage sustained by an employee, without any fault on the latter's part, where such damage is caused by the negligence of a fellow servant.

In a Montana case, it appeared that plaintiff's intestate was foreman in defendant's mine and while attempting to get off a hoisting apparatus, a skip, as it was lowered in the shaft, was by reason of the alleged negligence of the hoisting engineer in raising the skip without signal, caught between the skip and shaft timbers and sustained injuries resulting in death. The court did not waste any time in affirming the judgment for the plaintiff, it being plain to all that this case came under the statute.

The Alabama code contains a similar statute and the courts of that state have decided cases similar to the one mentioned above.

In a Michigan case, it appeared that the person operating the mining cage was not employed as an engineer but as a fireman, and that his being in charge of the hoisting engine at the time of the accident was in violation of the Michigan statute, which provides "that only a competent and trustworthy engineer shall be permitted to operate the cages and hoisting devices in all coal mines in this state."

The court would not hear the defendant because he had plainly violated the statute in employing an inexperienced man to operate the hoisting cage, and gave judgment for the plaintiff.

In a Wyoming case, it appeared that the plaintiff's injury was due to the incompetency of the engineer causing the cage to fall to the bottom of the shaft.

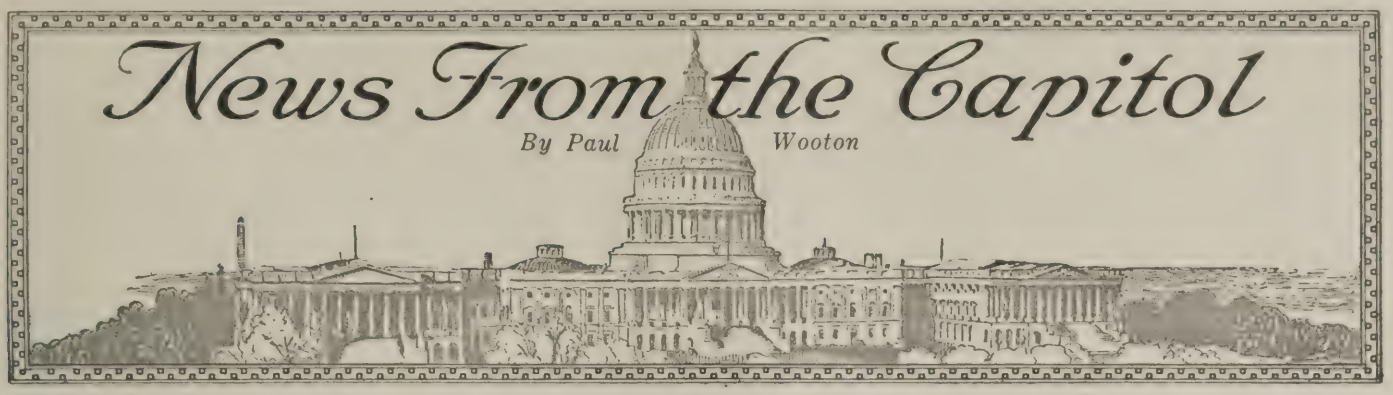
The court found that there is no statute in Wyoming defining the relation of fellow servants, and that while statutes have been enacted imposing certain duties upon an employer in specified cases and giving the right of action for damages where an injury has occurred as a result of a willful violation of such duties, they are not applicable to the instant case.

The court did, however, find that there was a statute in Wyoming which prohibited mine operators employing any person as engineer who used intoxicating liquor. It was shown that the engineer in question was a user of such intoxicating liquor, and for that reason the court entered judgment in favor of the plaintiff.

In questions of this nature, the answer is naturally found in the state statutes and in the decision of the various courts construing those statutes.

The courts are quite generally of the opinion, however, that the word "mining" as used in those acts is to be taken in a very strict sense, and not applied to prospecting, exploring or shaft sinking where the purpose is merely to discover minerals.

Use of Tar as a Fuel



Some tests that indicate in a practical manner the value of tar as a fuel have been carried out in England in connection with oil furnaces and burners, the tar being mixed in certain proportions with creosote. Of two tests made, the first employed a half-and-half mixture—that is, tar 50 per cent. and creosote 50 per cent.

In order to make it flow through the pipes, the mixture was heated in an overhead tank to a temperature of about 100 deg. F., and on its way to the burner it passed through a steam-heated chamber, raising it to 150 deg. F. At this temperature it was easily atomized and, it is said, burned satisfactorily at a low air pressure, namely, 15 in. of water gage.

In the second test a larger proportion—namely, 70 per cent.—of tar was employed, with of course 30 per cent. creosote. The conditions were the same and the result was, it is stated, equally satisfactory. The national importance of the use of tar in such a connection at the present time is self-evident.

Coal Distribution Plan Completed

Intrastate coal distribution plans have been completed by the Fuel Administration. The Fuel Administration describes the procedure in this important regard as follows:

The War Industries Board will decide what consumers shall have preference in securing coal; but the United States Fuel Administration has been asked to assist in the compilation of complete preference lists by obtaining reports and recommendations on individual firms from the state and local fuel administrators.

The crux of the new distribution plan lies in the compilation of these preference lists. All consumers of coal, except domestic consumers, will be recorded under the following classifications:

a. Railroads.

b. Army and Navy, together with other departments of the Federal Government.

c. State and county departments and institutions.

d. Public Utilities.

e. Retail Dealers.

f. Manufacturing plants on War Industries Board's preference list.

g. Manufacturing plants not on War Industries Board's preference list.

The first six classes will be given preference in coal shipments in coöperation with the plants of the War Industries Board.

The distribution of coal to consumers in the first two classes will be handled from Washington. Washington will also supervise shipments to a few vitally important plants.

The list of consumers entitled to preference as established by the War Industries Board will be obtained through a questionnaire sent to every manufacturing plant in the country using more than 500 tons of coal annually. This list, when compiled, will be furnished to each Fuel Administration district representative in the producing field which supplies the various states, and with these lists to guide them, together with weekly reports which will be required from each manufacturing plant, the state and local fuel administrators and district representatives will give their particular attention to building up proper stocks of coal at all essential war plants.

In order to control the distribution of coal to domestic consumers and industrial plants by retail dealers, the dealers will be required to make a special report to the state fuel administrators and from these reports deliveries to manufacturing plants not on preference list can be curtailed when necessary.

Under this plan of distribution each consumer should arrange for shipments from the same source of supply as last year, if possible. If diversion of coal for the war program or the zoning system will not permit this, the consumer should make every effort to form new connections, preferably under a contract arrangement, wherever a supply is available, before calling on the state fuel administrators for assistance.

Weekly reports to the state and United States Fuel Administration will show the actual shipments of coal to the various classifications of industries.

The plan is designed to fix definitely the responsibility and authority of the state fuel administrators. It provides for a complete system of reports for interchange of information between consumers of coal, state fuel administrators, district representatives and the United States Fuel Administration.

Complete lists of the preferred industries in every community in every state will be available as soon as the reports are compiled.

Zoning System Working Well

Operation of the zoning system is exceeding the fondest expectations of its creators. That it is an important factor in making possible a better car supply is asserted at the Railroad Administration. One of the most important changes is that now going into effect in the Kanawha region. This coal is being forced eastward, with the exception of that moving under permit. To make up for the westward movement of that coal, Chesapeake & Ohio, Norfolk & Western and Elkhorn coals have been barred from Indiana. This supplies more coal for Ohio, Michigan and the Lakes. Indiana has a surplus production. Indiana screenings for 60 days are to go all over the lower peninsula of Michigan and into Ohio as far east as Columbus. By keeping Indiana screenings out of Chicago a market is made for Illinois screenings, which have been almost a drug on the market.

Weekly Production Statistics

All records in the production of bituminous coal were exceeded when the output of the country's mines reached the unprecedented total of 12,465,000 tons during the week ended June 8. This exceeds by 17.8 per cent. the production during the corresponding week of 1917. The average daily production went well above 2,000,000 tons, which compares with a daily average of 1,791,000 tons during the week ended June 1.

The remarkable performance of the week and telegraphic advices indicating that the pace had been maintained during the week ended June 15, resulted in a more optimistic view of the situation than yet has been taken by Fuel Administration officials.

Anthracite forwardings came back to normal during the week ended June 8, when 40,754 cars were shipped.

Beehive coke production during the week ended June 8 was 638,000 tons, an increase of 4 per cent. over production during the week preceding. Labor continues to be the chief factor limiting the production of beehive

coke. Byproduct coke production for the week ended June 8 was 480,722 tons. This is a slight increase over production during the preceding week. Just at present the most important factor limiting production of by-product coke is repair of plants.

While car shortage continues to be the most important factor limiting the production of bituminous coal, the car supply is being increased rapidly and there is promise that the more important producing regions soon will have close to 100 per cent. car supply. Each week is showing an increase in the extent to which labor shortage is limiting production, and this factor bids fair to become the chief reason in retarding maximum output.

The figures referred to in the foregoing are estimates made by C. E. Lesher, the geologist in charge of coal statistics for the United States Geological Survey.

Domestic Consumers Must Conserve Coal

By seeing to it that coal is not delivered to domestic consumers in a greater quantity than is needed, with careful use, for the winter, the Fuel Administration expects to save for other uses fully 15,000,000 tons of coal. A national work to this end is being set on foot under the direction of T. C. Mahady. The plan has been tried out in Philadelphia during the past six months and is said to be entirely successful. An inspection system is expected to have an important influence in securing compliance by users.

Modifies Freight-Rate Increases

The drastic increase in freight rates made May 25 (General Order 28) is receiving some modification as a result of popular clamor. It was found that some intrastate rates were increased 300 per cent. by the provision made that all intrastate rates be lifted to the same level as the interstate rates prescribed in the order. The rates had thereby a double lift, first to the level of the old interstate rates and then the further 25 per cent. increase that was imposed on the earlier charges. Furthermore, the order changes the regulation in Section 5 entitled "Minimum charges."

"The minimum charge of $15 per car will apply only to line-haul shipments and not to brick, cement, coal, coke, logs, or sand and gravel and stone (broken, crushed or ground) on which the existing rates as increased under Section 2 of the order shall apply."

The Railroad Administration has also postponed until Aug. 1 the requirement that freight transportation shall be settled on a cash basis.

New England To Receive Large Tonnage of Bituminous Coal

New England is to receive 30,000,000 tons of bituminous coal. The Fuel Administration has apportioned this amount to that section after a careful study of its requirements. Steps have been taken to insure the delivery of 60 per cent. of that amount by Oct. 1. As New England forwardings in April and May were below the average which must be maintained, it will be necessary to ship at a higher rate during the next three months. Mines in central Pennsylvania have been ordered to double their New England shippings.

Enforcing Output of Clean Coal

Six mines have been shut down for disregarding the clean coal regulations. Three mines were shut down partially and the operators of 568 mines censured and warned to improved their methods. This report by the Fuel Administration covers the past six weeks during which inspection of output has been in progress. The report shows that 116 mines were preparing their coal properly at the time of the visit of the inspector.

Automobile Industry Receives Drastic Cut in Fuel Supply

Seventy-five per cent. less fuel must be used in the manufacture of pleasure automobiles in the season of 1918-1919 than was used in the fiscal year preceding. This drastic action was taken by Dr. Garfield after he had delayed a decision for some time awaiting action on the part of the War Industries Board as to the amount of steel which could be devoted to pleasure-car industry.

Restricts Industrial Expansion in Certain Area

Further industrial expansion in the East and in New England has been stopped by joint action of the War Industries Board and the Fuel and Railroad Administration. Development has reached the point where it is no longer possible to supply the necessary transportation for fuel, raw materials and the finished products. The order is intended to force new industrial activities in districts where fuel and raw materials can be transported by lines which are less congested. The restricted district consists of New England states; eastern and southern New York; Pennsylvania, as far west as Williamsport and Altoona; all of New Jersey and Delaware and eastern Maryland, not including Baltimore.

Inspire Labor To Do Its Best

Anticipating a more generous supply of coal cars, James B. Neaie, head of the production bureau of the Fuel Administration, is planning a nation-wide campaign to speed up production. As labor soon is expected to become the most important factor limiting production, Mr. Neale is directing his principal effort at this time to the task of inspiring labor to do its best. The campaign will begin in central Pennsylvania. Prominent men will have heart-to-heart talks with the workmen at the mines and operators will be urged to do their part in expediting production by providing every facility and convenience which will aid their employees to mine more coal. John P. White, of the Fuel Administration's staff, is among those who will make speechmaking tours to urge the miners to do all in their power to increase production.

H. F. Byrd has reconsidered his action in resigning as fuel administrator for Virginia. This was done at the urgent request of Dr. Garfield after he had received numerous communications from Virginia asking that Mr. Byrd's resignation should not be accepted.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

The Railroad Administration has increased its car supply so much that the mines in some new quarters are now put to it to hold up their end. It is necessary, somewhat generally throughout the bituminous regions, as it has been all the time in the anthracite and Alabama fields, to use all manner of persuasion and entreaty to get the men to work steadily and for full working hours. Every effort is being made to reduce absenteeism and to increase the ardor of the men.

The railroads' slow turn of cars has driven away the employees. Irregular work has given the men the holiday feeling. Wages have been raised to meet the impoverishment due to shortened hours of work. Consequently, it is now not necessary for a man to work every day to make a living. The wage was raised with that end in view. Now that there is work for every day and wages are so high that steady work is not imperatively required for the securing of a comfortable living, the high wage works continually against the maintenance of maximum output.

MERE SELF-INTEREST WILL NOT STEADY WORKMEN

There is no reason, however, why a patriotic appeal will not undo all that requires to be undone. The mine worker, like other men, is willing to work hard for his country, even if he will not labor diligently to secure a roll of banknotes. More men than ever are prepared to work overtime and are even willing to overexert themselves to help their boys and their neighbors' boys "at the front."

The union in the Shamokin (Penn.) district is making monthly instead of quarterly inspections of buttons, and it hopes by continuous pressure to keep the bulk of the mine workers in the union without the help of button strikes. When membership dues are paid promptly they do not appear so large as if allowed to run a full quarter.

Central Pennsylvania is working steadily, the necessity for a large tonnage being made plain by a number of speakers. In Ohio a strike of 350 mine workers occurred at the Kirk-Dunn mine in Columbiana County on June 13. The men alleged that the draft board granted deferred classification to three miners and denied that status to others. The strikers allege that those thus "deferred" are "just miners" and are not entitled to be singled out for exemption. The operators are charged with having sought favors for the three men and to have been indifferent as to the desires of the rest. The spirit of patriotism in Ohio does not seem as keen as in the anthracite region, where applications for deferred classification should be presented frequently, but are not.

PROSECUTING ATTORNEY SENDS MEN BACK TO WORK

A strike occurred also at the Pursglove-Maher Coal Co.'s Maher mine at Glencoe, in Belmont County, just west of Bellaire, Ohio, early this month, but the men returned to work on receiving orders from the prosecuting attorney, who notified them that the mining of coal was an essential work and must be pursued without any cessation.

In West Virginia a strike of 250 mine workers took place June 10 at the Bertha mine of the Quality Cement Coal Co., a mine on the Monongahela River in the north of Monongalia County, West Virginia, near the Pennsylvania state line. The men claim the weight of their coal is estimated and not weighed, and that the estimate favors the company. They also say that they desire to organize a union and that the company refuses to recognize the organization. The mine is conveniently situated to Point Marion in Pennsylvania, where "wet goods" are dispensed. The dry law of West Virginia is being strictly enforced, and men who, in visiting that pleasant Pennsylvania village, bring back more good cheer than the law allows are being arrested and jailed. As a result, despite the strike, order was maintained. On the evening of June 11 the mine workers announced that they would return to work, orders to that effect having been received from the union officials at Fairmont.

The operators in the Fairmont region are trying to induce men to mine coal who have never mined it before. A. C. Beeson, of the Four States Coal Co.; A. Lesle White and C. J. Ryan, of Clarksburg; F. J. Patton, of the Central West Virginia Coal Operators' Association; E. Drennan, of Elkins, and C. H. Jenkins and John A. Clark, Jr., of Fairmont, went to Washington last week and had a conference with Cyrus Garnsey, Jr., assistant United States Fuel Administrator. The State Fuel Administrator, J. Walter Barnes, accompanied them. The delegation presented to the Fuel Administration a scheme of awarding buttons to the coal miners who work regularly, the buttons to be a badge of recognition of service rendered.

FAIRMONT REGION NO LONGER A NONUNION CENTER

The union is putting its affairs in order in the Fairmont, W. Va., district, President Frank Keeney of District No. 17 having opened an office in the Deveny building, Fairmont. Frank Keeney is directing operations in Marion, Harrison, Barbour, Lewis, Mineral and Tucker counties. This list of counties varies from that designated by the Fuel Administration as the "Fairmont District." Note that Monongalia county is not included, but the action in the strike of the cement company, just referred to, suggests that Monongalia is in Keeney's jurisdiction. "Mother" Jones also addressed a meeting at Star City, near Morgantown, in Monongalia County, Sunday, June 16, as if she had a wider field of operations than the chief. But then who could put bounds to "Mother" Jones' activities?

Governor Cornwell, of West Virginia, is determined that the vagrancy law shall be closely enforced, especially in Mingo county, where he says in a recent letter to the operators there is an excessive amount of absenteeism, some men being absent from their working places two or three times in a week. In the letter he says:

MINGO, W. VA., MEN MUST WORK MORE REGULARLY

"I am advised that the Mingo County Council of Defense is seeking to diligently enforce the vagrancy act against those who do not work. To supplement the efforts of the Mingo Council I ask you to keep an accurate record of the number of hours worked by the men in your employ during the week, forwarding this record to the State Council of Defense each week and posting a copy of the same at the mine where the men are employed. The vagrancy act is a war measure and must be observed during the war."

The attempt of the West Kentucky Coal Co. to make an ancient injunction serve as against persons for whom it was not specifically written has failed. This injunction, dated 1907, restrained certain union officials and others from interfering with the operation of the mines. Sam Tosh and George Overby, officials of the union in western Kentucky, strove to prevent the mine workers from working for the company, and they were arrested for being in contempt of the instrument quoted. The lower court sustained the company, but the United States Circuit Court of Appeals at Louisville, Ky., reversed the decision of that court, declaring that there was nothing in the record to show that the strike of 1917 was a continuation of the strike of 1907 or that the defendants were engaged in the former strike.

Midway between Murphysboro and Sparta, Illinois, lies the town of Willisville, a Perry county mining town. Some few days ago there was funeral at this village and 100 men

quit work to attend it, but according to the company only 12 of these men were interested enough to actually participate in the ceremony. The company fined the men who did not attend the funeral, but quit work nevertheless, $2.50 apiece for unnecessary idleness. The men continued idle for a few days and then concluded that their idleness was a breach of contract. As a result they returned to work.

Operation of many of the mines in the now thriving Belleville, Ill., district was stopped recently by a strike of the employees of the East St. Louis & Suburban Electric Railway Co. for higher wages, and but for a prompt temporary adjustment of the dispute, subject to final decision by the War Board, there would have been a rather serious interference with production. A number of mines are located on or near the interurban divisions of the system, including the big O'Fallon mines near French Village, and miners of Belleville, O'Fallon, Lebanon and other St. Clair County towns are dependent upon the electric line to take them to and from work.

Drivers for Retailers Also Work Short Week

Trouble is being experienced by the St. Louis coal dealers. The drivers and other helpers are making so much money that dealers are having great difficulty in keeping the men at work. E. J. Wallace, secretary of the Missouri Retail Coal Dealers' Association, has called the situation to the attention of William F. Saunders, secretary of the Missouri Council of Defense, and has asked him to take some remedial action. "The drivers and other helpers," he says in his letter, "are making more money now than ever before and find it convenient to lay off a couple of days a week, leaving equipment idle, cars loaded on track and in a general way bring about demoralization in the retail coal trade."

Secret service men of the Government are investigating the discovery of 21 Mauser rifles in the garret of a coal miner's home at Beckemeyer, Ill. The weapons were seen by a child, playing in the garret, and she told Sheriff Welsh. He seized them and took them to Carlyle and turned them over to the Federal authorities. The miner, who was known as a pro-German, left Beckemeyer five months ago, but his wife is still living in the house and gave up the weapons without question. The miner is said to have been a member of the I. W. W.

There is evidence that the mine workers in some places do not understand how important it is to work whenever the Railroad Administration has been able to leave cars in the mine siding. At the Royal Mine at Swansea, near O'Fallon, Ill., in St. Clair County near St. Louis, William Deppe, a miner, refused to contribute to the Red Cross, and 110 mine workers struck and threatened even to riot.

Strike in Illinois About a Single Dollar

The manager followed Deppe into the mine and talked with him. Upon his advice, Deppe gave the manager a dollar for the Red Cross drive. As Deppe was said to be making $66 every two weeks, his fellow miners could not understand why he could not give a small share of it to that work of mercy. Nevertheless a strike or shutdown in a coal mine is an unpardonable offense against the commonwealth at the present time and it should certainly not be instituted for so small a purpose as to raise a dollar for the Red Cross.

The labor situation in the Southwestern district is the most favorable of any time in years. Miners are working well, and there are no strikes. Practically all the fines accruing against miners because of actions contrary to contract have by this time been paid in. A total of $16,000 in fines had so accrued, and the collection made goes into the treasury of the Southwestern association.

There were three strikes in which the contract had been plainly violated. At the Smith, Scott & White mine, 125 men were idle 49 days. In this case, the miners insisted that two men, who were discharged, be returned to work before the matter of such discharge was arbitrated. At the Packard & McWilliams mine, a smaller number of men were out 38 days, demanding that the firemen be promoted to crane jobs. At the Jackson-Walker mines, 1000 men were out 10 days, in an effort to organize the office clerks. In each case, the strikers finally returned to work, and the matters were taken up under the contract. Pressure was brought upon the leaders by the United States Fuel Administration, and by the miners' national organization. The operators plainly saw that these were cases—taken in combination—which would establish dangerous precedents, if the fines were not collected, and this view was taken by the national officials of the Fuel Administration, the miners' officials admitting the violation of contract. As a result, there is among the miners in general a sounder respect for contracts, as well as a more serious purpose to keep industry going.

The convict miners at the Banner Mine of the Pratt Consolidated Coal Co. mutinied on June 11, holding five white men including two fire bosses as hostages. They demanded that the warden of the penitentiary, J. P. Hall, be discharged. By the good offices of Dr. R. A. Smith, the physician convict inspector, the men were induced to return to discipline without the use of firearms or injury to person or property. The convicts at the Banner mine are men of bad records, and more trouble was, for a while, feared. However, the strike was settled and the mine started again at full swing Thursday, June 13.

The Royal Commission which met May 14 at Sydney to inquire into the wage controversy between the Dominion Steel Co. and its employees has rendered a decision which recommends that the company grant its men an increase totalling over $300,000 a year, the advance to be dated back to May 1. The highest rate of increase goes to the lower-paid men.

Labor Shortage in Anthracite Mines

Apart from the draft, even apart from absenteeism, the labor situation in the anthracite region is desperate. The labor force before the war was not adequate. It has been made less adequate since by the drain to the munition factories and the enlistment and draft. For a while some good results have been obtained by drawing on culm banks and by working the easier-won coal, but these resources are narrowing. It is necessary to do something more to relieve the situation than merely provide for exemption from draft.

In bituminous mines most miners want a working place of their own. However, with a little coaxing, or when men are numerous, you can get them to "double up," especially where cars are delivered at the face. Why then must miners in the anthracite region work in pairs—a miner and a laborer? The answer is that the miner prefers that method because in most cases he gets the laborer to do the work while the miner secures the major part of the pay. Let the miner have a place alone and he will have to do all the work. Of course, he will also get all the pay, but in that event he will have to work harder than he would if he had a laborer. The miners desire to maintain the present condition of things. Some of the miners leave their working places and go home quite early in the day, trusting the faithful mine laborer to go on alone with the work of loading the coal. This practice some companies have been trying to change, contending that the trained miner is paid well to look after the greenhorn laborer and should stay in the place and at least attend to that duty if he does nothing else.

The Hudson Coal Co., at the Coalbrook colliery, Carbondale, Penn., has been endeavoring to induce the men to work alone, one man to a place. As a result the 1300 mine workers struck on June 12, tying up the operations at the colliery. The mine workers have 15 grievances and are willing to arbitrate all but this one. They explain that there are a number of the 1300 striking men who are too old to work a chamber alone, and that is the principal reason for demanding a laborer. If that is an honest reason, it will be quite possible for the company to let these old war horses go on working double and let the younger men work alone. Unfortunately, there is reason to fear that the opposition to the rule "One man, one room" arrangement, so popular in the bituminous region, does not arise from any compassion for the old men but from a desire

on the part of the miner to profit from the lower-paid labor of his assistant.

The following letter from a correspondent in the Southern anthracite field is interesting as throwing light on one of the reasons for the shortage of anthracite coal. It shows, what *Coal Age* has frequently contended, that the mine worker has been allowed to visualize a part of his duty as if it were the whole.

"The newspapers and the coal-trade journals have repeatedly told us that there will be a shortage of anthracite, and that if the present output is all that can be obtained there will be a coal famine in the United States next winter that will make the "heatless Mondays," from which the people suffered last year, seem like a Turkish bath.

Miners Must Help or Homes Will Be Cold

"What such a possibility involves we can realize by recalling the suffering that then existed among the poor people in the cities, the long lines of women and children standing with buckets waiting their turn to buy a bucket of coal to keep up the one little fire in their apartments, the riots that took place in Philadelphia where the police were overpowered, bottoms dropped out of coal cars and contents carried away by men, women and children who needed the fuel to keep their homes from freezing.

"The increased consumption of anthracite has been one of the remarkable features of this demand for fuel, and this feature of it can be traced to the doubling and quadrupling of the number of workmen employed in the munition plants, shipyards and other industries that are busied in producing material of war. Most of these are located on the Atlantic coast and so are dependent upon anthracite for fuel. In addition the cantonments, where the men receive their training, require over two million tons of fuel to render them habitable.

"All the coke that the country can produce is needed to supply blast and other furnaces for the production of iron and other metals. Plants that formerly used coke have had to replace that fuel with broken and egg coal, making a still further demand on the anthracite industry.

"What is being done in the hard-coal region to meet these extraordinary war conditions? The reports of shipments show an increase over last year; but is that increase all that it should be, and are the men in the mines doing their share to produce a maximum output of what has proved to be one of the greatest essentials of the war?

Here There Are More Men and Less Coal

"I have been permitted to look through the records of one of our large anthracite corporations, and I have found that the increase in their tonnage is not coming from the mines but from the washeries. One of these was not running at this time last year and another is now running double-shift in place of single-shift.

"I was allowed to look over the daily report of tonnage for the month of May and found that up to May 27 the collieries had worked practically the same time this year as they did in May last year, but that there were 13,103 less mine cars of fresh-mined coal dumped in the breakers. In looking over the records of six different collieries I found that with the same number of hours worked they dumped 13,513 less mine cars.

"As the average amount of coal obtained per mine car is about 2½ tons, the total loss in tonnage amounts to 32,757 tons. On inquiry as to whether in the opinion of the officials of the company the severe falling off in fresh-mined tonnage was due to the loss of miners going into the United States Government service, I was advised that it was not, as in the month of May this year there were 1785 contract miners on the payrolls of the company as against 1665 in May last year. On further inquiry as to what they thought was the reason, my attention was called to the absentee statement which is made out daily. This showed that from 8 to 15 per cent. of the men are absent from their work each day. The falling off in tonnage just stated is almost in proportion to the average absenteeism from these collieries. Clearly the decrease in tonnage arises from the fact that the miners and other employees are not coming to their work regularly and have failed in their duty.

The miners should realize that we cannot prosecute the war successfully unless we have fuel, and that in providing fuel they are providing the munitions which will enable their boys to protect themselves against the enemy. Without these munitions their sturdy defenders will suffer the same fate as the earlier regiments of English and Canadians, who went unprepared to the front and who came back with only 10 per cent. of their men.

"Attention was also called to the fact that every possible excuse is being made for a holiday and that the men are not working effectively or trying to do their best. There seems to be an impression among the miners that by investing in a Liberty Bond and paying out $5 to $10 a month they are doing their full duty toward winning the war. Money is needed, it is true, to buy fuel and other things, but only when the fuel is produced can the money be used; and without fuel the war will be lost."

The remedying of the draft situation is not proving easy. Apparently the draft boards are not the main cause of the trouble. The general sentiment of the anthracite region is that a man who is called by the draft and seeks exemption is a "slacker." Against that sentiment the draft boards must actively oppose themselves if any success is to be obtained in maintaining a force to man the anthracite mines.

It is not enough to accept without question all bona-fide requests for exemption. Such a passive relation to a desperate condition will not save the anthracite supply. The men conscripted are enterprising, daring and patriotic. They refuse to ask or to accept exemption or deferred classification, and they dread criticism and the innuendo more than they do physical dangers.

Production Scores vs. Baseball Scores

However, the union leaders may be able to bring a new sentiment into being, and to this end President Frank J. Hayes has been addressing mass meetings. The operators might well express their opinions in meetings with their men. Most of the men are disposed to listen with approval to suggestions from that source. Operating officials are apt to underrate their influence with their men. With a good cause a competent speaker, who is not merely a fluent talker, but has the correct point of view, will never fail of receiving a proper reception—provided, of course, that a certain degree of rancor does not exist which has to be allayed before the argument is presented.

In order to increase the output of the miners a competitive plan has been proposed calculated to arouse as much interest in output scores as has hitherto been expended on the purposeless scores of baseball and football matches. Competitions for nation-saving are to be the worthy successors of competitions for less noble ends.

Of course, it would not be fair to pit colliery against colliery, for some are large and some are small. The race would be won before it was started, and such an unfair competition would arouse no interest. It is proposed, however, to make the contest one for average tonnage per capita, and so put all the collieries on a more even basis. A conference was held recently at Wilkes-Barre to put this plan in immediate operation, and prizes will be awarded to that miner and his helper who produces the largest weekly tonnage.

Work One Day a Year for Uncle Sam!

The Rev. Oscar Berkley, a "circuit rider" in northern Kentucky, who preaches part time and mines coal part time for the Gravity Coal Co., is endeavoring to start a general movement looking to the donation of one day's work to the Government by every man in the country each year during the war; and is urging that on the same day every merchant donate his profits for that day to the same Government fund.

Berkley claims that this would not work a hardship on anyone, and would make it possible for the Government to secure much additional revenue and do it without increasing taxation materially. He claims that there are thousands of laboring men who would like to assist the Government, but they cannot afford to buy a Liberty Bond. Berkley has apparently overlooked War Savings Stamps.

EDITORIALS

Why Have Two Tons in America?

NO SYSTEM is more provocative of fraud and profiteering than the use of a double standard of weight—the short and the long ton, both tons being known in usual practice by the shorter appellation "ton," as if there were but one standard of weight.

The public does not know which ton is meant when the word is used, the one with 2000 lb. or the one with 2240. As a result, where coal is sold to the retailer by the long ton he can retail it by the short ton and make 12 per cent. of profit. Most retailers are honest, but the temptation is strong and should be removed.

The old English ton, the long ton, used principally in the old coal fields, did have the advantage of being divided up according to the table of weight—14 lb., one stone; two stone, one quarter; four quarters, one hundredweight, and 20 hundredweight, one ton—but, in America, of these divisions one only remains, and that division is misleading in name, for everyone in this country regards a hundredweight as 100 lb., whereas when it is a long hundredweight it has 112 lb. and not an even 100.

The short ton is making its way even in Pennsylvania, the oldest of coal-producing states. But in that commonwealth a state report is made in which the main tabulations are in short tons and the tabulations of the inspectional districts are in long tons. As a result the figures to the layman appear hopelessly discordant, especially as the reports show the long ton as the "ton," though the short ton is specified as a ton of 2000 pounds.

When the long ton disappears we can avoid the use of the adjectives "long" or "gross" and "short" or "net." The use of the word "short" always suggests fraud, and for that reason should be abandoned in all the states. The words "gross" and "net" suggest a different idea from that which we seek to convey. If we speak of the "gross" tonnage of the anthracite region we should mean the whole tonnage, including what is employed in the raising of the steam for the operation of the mines. The "net" tonnage should be that part of the whole tonnage available for public consumption.

Why Should We Reward It for Its Failure?

REPRESENTATIVE CHARLES B. SMITH of Buffalo recently advocated, unsuccessfully, in a letter to President Wilson, that the Treasury Department be put in charge of the work of the Fuel Administration because of the failure of the latter to supply the needs of industry. His suggestion seems to advocate quite a natural evolution, entirely in accord with what has been going on in the past and with what is only too likely to occur in the future.

For example, the Government, by extremely unfair restriction of the railroad business, prevented the development and maintenance of the railroads. They dwindled under the malignant influences of excessive rate regulation till they fell, like a dried apple from the tree, into the lap of the Treasury Department. Since then Mr. McAdoo has been busy doing all those things which the railroads were forbidden to do. We have hope that he will succeed in his administration because he has been suffered to make all those provisions for successful operation that the Interstate Commerce Commission industriously banned.

But the evil that was done to the railroads before Government ownership lives still, though the railroads are now federally owned and allowed to take money from the public with both hands. Not that they are taking a dollar too much, be it understood, not that their traffic regulations are a bit too rigorous, far from it. But it must be conceded they are more severe by far than they ever were under private ownership. We now know, if we could not see it before, why under such ownership the railroads failed to meet the public demand.

The fuel supply may fail to satisfy needs, just as the railroads failed. The trouble is not that the business of producing fuel is conducted with inadequate skill, or that fuel as a whole cannot be produced in adequate quantity, but that the transportation facilities provided are unequal to the work required of them. The coal can be mined, but cannot be brought to market. As the railroads, ruined by the Government, fell into the hands of the Treasury Department, so now the Fuel Administration, handicapped in its efforts by the inefficiency of the Government railroads, is threatened with absorption by the department which controls the railroads.

The railroads have been wholly to blame for the fuel shortage, mainly by reason of their inadequacy of equipment, but partly because of an attempt made by the Railroad Administration to exploit the coal operators. The railroads promised a full stint of cars to those operators who would sell their output to them at a reduced cost. It is even alleged that the railroads turned over some of the coal thus obtained to certain industries that they favored. As a result many mines worked only fitfully and other mines had an excess of cars. This was a waste of equipment when every car was needed, and this, because a mine with cars left over at the end of a day, or one which does not load its cars early in the day, is wasting car service.

But this was not all. The men working at the mines which run only irregularly became dissatisfied and quit for other work. So when the wrong was adjusted by Mr. McAdoo on his return from his Liberty Loan campaign, the evils which followed in its train were not wholly undone. The irregular work has done much to destroy the morale of the mine workers.

It is well known that men get careless and indifferent when work is not steady. You cannot urge them to do their best, for they naturally counter with the answer: "If they want the coal, why don't they give us the cars? They are always calling on us to get out a big

tonnage, but they don't seem anxious to hold up their end; and what is more, they are not giving us a square turn." Because of the discrimination of the Treasury Department, through its branch, the Railroad Administration, it was hard to keep the men keyed up to their work.

Another way in which the Railroad Administration has hampered the Fuel Administration has been by the inadequate purchase of coal for storage. Of course, the effect of this is local, as in most places the public has been willing and more than willing to take what the railroads would not buy, but in such places as it occurs it is most distressing. The Railroad Administration tried also to get an exemption from the zoning rules. It thought it was justified in going beyond the zones laid out for the public. The transportation lines were prepared to haul the fuel that they preferred for long distances, though other parties had to satisfy themselves with coal such as was mined nearby. In this way the roads failed to make the utmost use of their equipment.

And for these inabilities and offences of the Railroad Administration, there are those people who suggest that the Fuel Administration must pay. It is the old story. The man who fails will suffer, and meantime the man who makes him fail enters into his estate. The Railroad Administration may not be blamed for failing to do the impossible. It must be blamed, however, for some things it has deliberately done to prevent the orderly operation of the mines. But alike where blamable and unblamable, the Railroad Administration's failure to supply cars is the cause of the coal shortage. Shall we therefore reward the Railroad Administration by placing it in control of the production of fuel?

Save That "Shovelful"!

WE ARE told (and have no reason to doubt the truth of the assertion) that the country faces a coal shortage amounting to several millions of tons. This is a time of national necessity, a time when every one is anxious to do "his bit"—and without exception every one's bit is his best. Admonitions to economize in the use of food meet the eye at every turn—in the street car, on railway trains, in every post office, courthouse, public library, town hall and schoolhouse. Even the signs along the highway preach the same gospel.

But if food is important as a national resource, as a war munition, so also is fuel. It is highly probable that fuel to comparatively as great an amount and value as food can be saved through care and diligence. It has been repeatedly pointed out that the householder by saving a shovelful of coal a day can in the aggregate save —that is, release—a vast amount of fuel yearly for the production of much needed munitions. The time has now arrived when all users of coal as well as householders must save fuel, must save that "shovelful" per day.

Fuel can be saved in many plants that are already thought to be fairly economical. Not long ago a certain plant in New England that was engaged in the manufacture of wire sought to improve the efficiency of its already efficient power plant. The wisdom of this attempt was doubted by some as the plant was known to be modern and well kept up. After three months of operation, under the supervision of an expert, the efficiency of the boilers and furnaces had been increased 16 per cent., the losses in flue gases had been cut down 13 per cent. and the loss of unburned fuel through the grates had been reduced 2 per cent. When all of these economies were traced back to the coal pile it was found that the savings effected amounted to 1500 tons of coal yearly, or about 30 per cent. of the former fuel consumption.

All this was accomplished without one cent being spent for changes or alterations. The economies effected were secured through careful and skillful firing, strict attention to details and eternal vigilance. The point of maximum efficiency has not yet been reached in this plant. When this point is attained, however, the task of fuel conservation will have only begun, for maximum efficiency must then be maintained.

The foregoing shows what possibilities exist in some plants that are thought to be already fairly efficient. If similar and equal economies were to be made in other plants throughout the country—and this is entirely possible in a great percentage of them—the saving to the nation and to the cause of democracy and humanity would be immense.

Hounding the Devil

OVERWHELMED by our marines at the recent battle in the vicinity of Chateau-Thierry, France, the gasping Huns summarized what they thought of our boys by the ejaculation *"Teufelhunde"!* To the Prussian mind, filled with the intoxicating fumes of conquest and the immoral creed of the Hohenzollerns, there was something devilish, something unearthly in the grim earnestness and strange intensity that characterized the fighting of our lads in khaki. They could not understand it. "Devil-hounds," they called our boys. But though they coined the epithet they did not realize its real meaning, its full significance.

Our marines—the boys who are always the first ones to fight—know what they are doing, however. They are *hounding the devil.* They are exorcising the evil spirit of Prussianism which has taken root in the hearts of the German people—the spirit which has made a shambles of Europe, the spirit which recognizes no sense of decency, no understanding of what civilization means.

Little wonder that the Germans failed to discern the spiritual flame that fed the enthusiasm of our boys and exalted their fighting. "We're here to avenge the women and children of Belgium," was the unuttered cry as our lads pressed forward. "We're here to demand an accounting for the lives of those who went down with the 'Lusitania.' We're here to back up France, bled white, and to fight shoulder to shoulder with our war-weary English brothers. We're here to see that Freedom once more reigns over the earth."

There will be no compromised peace. The determination which marks the faces of "Our Marines," as shown on the colored supplement to this week's *Coal Age,* is full evidence of that.

Don't wait to be urged to join the War Savings Stamps army. What if our men in the trenches waited to be urged?

DISCUSSION BY READERS

Holding Men in the Mine

Letter No. 1.—A short time ago reference was made in *Coal Age* to the difficulty experienced by many mine foremen in holding their men. Various arguments were advanced as to the cause of this difficulty, and suggestions were made of methods of overcoming the trouble; but it appears to me that these did not emphasize sufficiently the chief cause of men constantly wandering from place to place in search of better conditions.

There is no question but what good living conditions, the social atmosphere and steady work at the mine go far toward satisfying men and holding them in their places. Still, where all of these conditions exist, it is frequently observed that the men are restive and the mine cannot be operated to its full capacity, because of an insufficiency of men. In the common vernacular there is "a screw loose somewhere."

Outside of the conditions just mentioned, there are two prime causes to which our troubles may be attributed. The seam of coal worked may be thin, the coal hard to mine, the roof or floor, or both, soft and troublesome; or there may be much gas or water to contend with in the mine. All of these conditions are such as are beyond the control of the management and for which they are not responsible. There is another potent cause, however, that every wise management will strive to eliminate; that is, the disposition of the foreman toward his men.

A Foreman's Chief Asset.

The chief asset of a mine foreman is his reputation. Upon this will depend his success in holding his men. A foreman's reputation is known far and wide and is the chief factor in drawing or repelling men. His reputation will live and follow him wherever he goes. Important as are the many other requirements of a successful foreman, his reputation for square dealing outdoes them all.

It may be asked, What is meant by "square dealing"? In a nutshell, it is the treatment of everyone alike, having no favorites and making no promises that one cannot certainly fulfill. A foreman will sometimes make a promise to a man in good faith and, later, find that he is unable to fulfill it. While his reasons for not keeping his promise are plausible, they are not satisfying. The man concerned is dissatisfied and, for this reason or some other slight cause, he quits and goes elsewhere. The foreman may be resourceful in explaining his conduct satisfactorily to the management and in leaving no room for argument with his men, but this will not keep them satisfied.

Equally efficient with the foreman who is unable to keep his promises is the man who treats his men in a surly, disagreeable manner, snapping them off with "If you don't like that, you know what you can do," or some similar unkind response, generally accompanied with a few cuss words, by way of emphasis.

The all-round successful foreman is the one who is able to win and hold the respect and confidence of both his men and his employers. To do this, he must be honest and sincere in all that relates to the men and the company. He must, of course, be a practical miner and a good judge of men, as to their character, disposition and capability for performing work.

Thomas, W. Va. W. H. NOONE.

After the War, What?

Letter No. 2—There is no question, in my mind, but that there will be a large business done at the close of the war, as remarked by P. H. Kennedy, *Coal Age*, May 25, p. 979. Whatever is the outcome of the war, there will be a great change in the industry both of this country and of Europe. The work of reconstruction that will then have to be performed in Belgium, France, Italy, Russia, Greece, Turkey and Servia will require a large amount of material and of men.

In the early stages of the war when Germany had to maintain the fight on all sides, she reported from 75,000 to 80,000 men killed or wounded a day; but. 75 per cent. of these were later returned to active service. The same is true, but to a somewhat lesser extent, in respect to the armies of France, Great Britain and Italy. Russia had a large percentage of her men slain and the toll of death has been very heavy, also, on the southeastern fronts, among the Turks of Gallipoli and Bagdad.

There will be no immigration, in this country, for a long time following the close of the war. The men who survive the struggle will be needed at home. Workmen in our own land will demand and receive higher pay than what they are getting today. The end of the war will be their opportunity and they will not be slow to seize it, in an effort to secure their share of the increased business.

The demand for coal will be far greater at the close of the war than it is today, because the United States will have to make good the deficiency in other countries, by the export of much-needed fuel. It is now rumored that Canada will have to burn wood, the coming winter, as what coal she can get will be needed by the railroads.

Another great market for coal will be South America, which has been largely supplied, in former years, by Germany and England. It has been stated that it will require five years to repair the coal shafts of France and put those mines in shape to supply that country with coal, which is quoted there, today, at from $30 to $70 a ton. Italy will need coal much more when the war is over than she did in peace times.

In my opinion, when the war ceases, America will be more than 50 million tons short. In view of these facts, it behooves every man to study and plan labor-

saving devices and schemes, to the end that we may be able to produce more coal at a reduced cost and a minimum loss of life. New mines must be opened in the United States and Canada. In this strife for increased production, however, safety first in operation must be the prime consideration. C. McMANIMAN.

Rawdon, Canada.

Practice in Mines in England

Letter No. 2—The letter of Robert Laverick, *Coal Age*, May 11, p. 889, interested me much, as it recalls some of my experiences in the mines in the North of England. I remember that, not long ago, mention was made of the frequent change in mine officials, and the claim was made that men employed a long time, in the same position, fall into ruts and fail to adopt the best up-to-date methods.

With all due respect to the operators in this country, I often think that the methods they employ in the management and operation of the mine do not compare favorably with mining customs in the counties of Northumberland and Durham, where I formerly worked. I have known men to work in those mines and hold practically the same position all their lives, and their sons have taken their places when they were incapacitated by reason of age.

In my opinion, more attention is given by English operators to the care and comfort of their men than is generally practiced in this country. While sinking a shaft that may take one or two years before the coal is reached, the company builds comfortable houses for its men and these are supplied with all the conveniences of life. It was not uncommon for each house to have a large yard or garden and the miner with a family was often supplied with 1500 cwt. of coal free, every two weeks, if desired. Miners living beyond the 3-mi. limit were obliged to pay 50c. for hauling the coal to their homes. A miner living in another than a company house was allowed 12c. per working day.

Welfare Work Years Ago in England.

Social conditions in a village or camp received special attention. Reading rooms, club houses and a large conference hall are provided, where meetings can be held and the miners' brass band can practice, or first-aid teams receive instruction. A small fee is charged to each man's account for the upkeep of these privileges. The company also furnishes a large field for athletic sports, and contests are held annually. There is also an annual flower show. A man who plays an instrument, a good football player, or ambulance man, is given every encouragement to improve himself. Men who hold deputy or examiner's certificates are certain of employment when the first vacancy occurs.

There is a company doctor who instructs the men in first-aid work and attends their families in case of sickness, for which each miner is taxed 18c. every two weeks. A hospital in the nearest town is supported by the miners contributing 25c. each quarter. An up-to-date rubber-tire ambulance and two first-aid men always convey an injured man from the mine to the hospital.

The ambulance, costing from $300 to $500, is generally supplied by the men, while the horse, driver and stable are provided by the company. British mines pay weekly and the drag system of deducting store accounts and other bills from the men's pay is unknown. A police officer is installed in each village, and any abuse of property must be paid for, or the offender is given 14 days to repair the damage.

A good feature of these mining towns is the coöperative stores run by the miners. The men are given no credit at these stores exceeding the amount of their interest. The store is managed by a committee of miners and the company is not concerned. The store pays a dividend every quarter. No junk is handled, but only the best grade of goods is supplied. The scheme of the coöperative stores frees the company of any suspicion or charge of unfairness in dealing with their men. Such are the practices in the mining towns in the North of England. T. GOLDON.

Clinton, Ind.

Loading and Shipping Clean Coal

Letter No. 10—In connection with the question of producing clean coal, which has been under discussion in *Coal Age*, permit me to describe briefly a practice in France, in 1896, which had for its object the loading of clean coal by the miners. I do not claim that the same practice could be applied now in this country; but it is interesting as showing what care was taken, at that time, to secure the shipment of coal of good quality.

It was my first experience in coal mining, and I was given a job of collecting samples of coal from the cars sent out of the mine and preparing them for analysis. In performing this work, I was stationed at the top-landing of a shaft, having a daily capacity of 1600 tons. The shaft penetrated 16 different seams of coal ranging in thickness from 14 in. up, the average being about 3 ft. Several of the seams worked produced very dirty coal, owing to the presence of partings of gray slate and bituminous shale, varying from a half-inch to several inches in thickness. Other seams produced coal of the best quality.

In the working of the poorer seams, it was necessary to mine the coal in benches, in order to separate the impurities from the good coal. Many of the miners would mix the black partings with the coal they were loading, whenever they thought that the foreman would not be around. This practice, however, was held in check by a fine that was imposed upon a miner when his coal showed an increased percentage of ash above the standard fixed by the mining engineer.

Preparing the Coal in the Breaker

The breaker was divided into two parts, one for the loading of the coal coming from the best seams, while the other received the coal of poorer quality. The cars containing the good coal were conspicuously marked to avoid the mistake of sending them to the wrong side of the breaker. Coal of the poorer quality underwent a process of washing, which was not necessary in the case of the good coal.

The samples collected each day were submitted to a careful analysis to determine the contract price to be paid the miners. These prices were continually changed to conform to the changing quality of the coal. It was

my duty to collect these samples of coal each day, and for that purpose I was given a slip bearing the numbers of certain working places from which samples of coal were wanted that day. I had willow baskets each numbered to correspond to the numbers on the day's slips. As the cars came out of the mine, I was instructed to take a few pounds of coal from each car bearing a number on my slip, and to put it in the basket marked with the same number.

I continued to do this during the entire shift, after which the coal in each sample basket was powdered, ground and divided so as to reduce the size of the sample to about 1 lb. This was placed in a small sack, which was labeled with the name of the seam and the number of the room where the coal was mined. It was my duty to deliver these sacks to an office where they were sealed by another person and sent to the company's laboratories for analysis.

The plan that I have described may seem very elaborate; but, since the miners never knew the day when their numbers would be chosen and samples of their coal taken, it had the effect of making them very much more careful to load only clean coal that would stand the test of the analysis made by the company. It is true that a few miners would run the risk and load some dirty coal at times; but the practice frequently brought them to grief when payday showed deductions made for impure coal. It was only later, when working at the face, that I came to understand the purpose of the sampling of the coal at the top of the shaft.

Peru, Ill. GASTON LIBIEZ.

Interpreting Mining Laws

Letter No. 3—The inquiry of Chas. Martin, *Coal Age*, June 8, p. 1080, springs a live topic in respect to the varied interpretation of our mining laws. Reference was made to this in the discussion of several points of the anthracite law some time since (*Coal Age*, Vol. 12, pp. 294, 463).

The two questions now raised by Mr. Martin relate to ventilation, and it must be admitted that the reading of the Pennsylvania bituminous law lacks clearness in respect to the matters mentioned. When attempting to interpret the meaning of a law, it is necessary to ascertain, if possible, the intention of the law makers, which will generally throw light on the meaning of the words used. It is not always an easy task to do this. Such is particularly the case in respect to mining law, where the law makers have undertaken to frame a law in accordance with the information gleaned of matters regarding which they themselves are wholly ignorant.

Referring to the first question of Mr. Martin, we note that the law specifies clearly the limits of the distances apart of crosscuts in room pillars, but gives only the maximum distance apart of crosscuts in entry pillars. The fact that the law permits crosscuts in entry pillars to be spaced 200 ft. apart, while those in room pillars are limited to 105 ft., has raised the question in some minds as to the reason for this.

A little reflection will enable most mining men of practical experience to realize that there are two conditions affecting the distance apart crosscuts should be made: (1) Driving crosscuts too close together increases the expense for yardage, weakens the pillars, and necessitates the building of more stoppings, requiring extra labor and material and affording greater opportunity for the leakage of air and impairing the efficient ventilation of the mine. (2) Driving crosscuts too far apart increases the danger of the accumulation of gas at the working face and necessitates the erection of long lines of brattice to conduct the air forward.

Keeping these conditions in mind, let us suppose that a pair of headings have been driven, say 75 or 100 ft. beyond the last crosscut, when the increase of gas feeders in the coal makes it advisable to drive another crosscut to keep the face clear of gas. There is nothing in the law to prevent this being done, and the foreman is free to use his own judgment. It is hardly to be supposed that anyone will deny that it is possible, with safety, to drive crosscuts farther apart in headings than in rooms, because the erection of a good brattice will keep the face of a heading clear, which is not always possible in a room.

What is a "Return Airway" in the Meaning of the Bituminous Mine Law?

Regarding the second question that Mr. Martin asks, it does not occur to me that there is so much difficulty in interpreting the meaning of the law, which states plainly, in Art. 10, that locked safety lamps must be used where gas is generated in quantities sufficient to be detected by an approved safety lamp.

In my opinion, it will make no difference whether gas is found in the first or the last room on a split of air; but the entire air split must then be worked with safety lamps. It would seem absurd to allow an air current to pass through a gob section and then permit it to ventilate live workings.

My understanding of a return airway is that it refers to a passage conducting the current from the last crosscut inby, back to the main return airway. The wording of the law quoted by Mr. Martin makes it unlawful to use the return air from a section employing from 70 to 90 men, for the ventilation of any other place or places. It must be conducted at once out of the mine.

Perryopolis, Tenn. R. W. LIGHTBURN.

Nature of Mine Explosions

Letter No. 1—I note with some satisfaction that the editorial synopsis to the article entitled "Nature of Mine Explosions," by H. E. Gray, *Coal Age*, May 18, p. 930, speaks of "air waves," "trill of the air," and "detonation" as being phenomena of an explosion in a mine. From the illustrations given as Fig. 1 and Fig. 2 in that article, it would appear that the wave motion produced by a blast was very similar whether the blast was projected into the free atmosphere or into the confined mine air, which I am inclined to think is not the case.

However this may be, I am pleased to note that there are some others who believe in the possibility of detonation taking place in the roadways of a coal mine when an explosion therein has been once initiated. I am a strong believer, myself, in the theory that *detonation* of a modified form takes place in many destructive mine explosions, although the real signifi-

cance of this term is not strictly the same as when it is applied to an explosive fired by a detonating cap.

To my mind, assuming explosive conditions exist in the mine air where a heavy blast is fired, there appears to be no reason why the same vibratory wave set up in the detonator should not be communicated alike to the explosive atmosphere about it, as to the charge of powder in the hole, and thus produce the so-called "trill" terminating in the peak of the vibratory flame.

The Development of a Mine Explosion

Mr. Gray has mentioned the well-known fact, which has been so often observed in the days of the extensive use of black powder for blasting in mines, that a space of 200 ft. or more intervenes between the point where the shot was fired and that where the destructive violence of the blast is first manifest. In this intervening space, little damage appears to have been done. Beyond this space, Mr. Gray states that the mine air trills or explodes, though he does not go on to explain what would be most interesting, the development of the process.

In the hope of provoking some valuable discussion on this point, permit me to restate a theory that I worked out some years ago; namely, that where a blow-out shot occurs, resulting in much of the force of the explosion being exerted on the mine air, a second explosion will result from the ignition of the heated gases and fine dust projected into the air. I claim, further, that it is this second explosion that is responsible for the wrecking of the mine which follows.

One noticeable fact worthy of consideration in this connection is the finding of the men killed by the blast, lying a short distance from the manhole where they had taken refuge when they fired the shot. To my mind, this circumstance proves that they were warned of the danger by the undue force of the exploding charge and had fled but a short distance when they were thrown down and killed by the second explosion, which wrecked the mine.

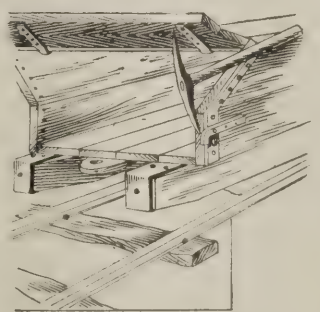
Incubatory of an Explosion

The notable mine explosions, at Altofts and Blackwell, furnish good illustrations of my claim that the 200 ft., more or less, of space from the point where the shot was fired represents the size of what may be styled the "cartridge" of explosive gases and dust that wrecks the mine. I may be permitted to style this development as the "incubatory" of a coal mine explosion.

Some years ago I observed, at an ironworks, what may serve as a practical demonstration of the explosion of a mixed gas-and-dust cloud, when coming in contact with fresh air or oxygen at a sufficient temperature. I was watching the workmen cleaning the dust out of the flues that carried the gases from the top of the blast furnaces to the boilers. As the dust was scraped from the flues, it fell a distance of 15 ft. carrying with it much of the absorbed flue gases. In falling through the air the dust cloud took fire and passed away in smoke. This was a frequent occurrence at the ironworks.

Although Mr. Gray has not described what he calls the "trill" of the mine air as a *detonating wave*, I believe that such is his meaning and that the two are, in effect, identical; because he says that "the climax is reached by a fine vibratory trill movement, and the real detonation of the mass immediately follows."

Without doubt, it is the earnest desire of each one to do everything possible to prevent the occurrence of mine explosions. But, since these explosions most usually originate in the improper use of explosives, more attention should be given to the charge limit, the use of permissible explosives instead of black powder, and the abolishment of shotfiring by miners or other unauthorized persons. Also, experience has proved that the safest policy is to treat permissible explosives with the same care that is customary in the use of black powder, which is seldom the case.



James Ashworth,
Vancouver, B. C., Canada. Mining Engineer.

Mine-Car Door

Letter No. 3—Referring to the inquiry of V. C. Robbins, *Coal Age*, June 1, p. 1031, relative to a suitable mine-car door for use in a 38-in. seam of coal, I assume that the car is so nearly the height of the seam that the coal cannot be loaded over the side but must be put into the car at the end. Although I have never seen a car equipped for that purpose, a few suggestions may prove of service.

While it is possible to design a car with the door swung from the bottom so that it can be laid down flat while loading, it does not appear to me that this suggestion of Mr. Robbins is an essential requirement. The usual arrangement is to swing the door from the top of the car and this, to my mind, is less cumbersome and better adapted for use in a shaft equipped with a self-dumping cage. At a mine employing a good blacksmith, it will not be difficult to equip the mine cars in use with doors swung from the tops of the cars.

It is a common practice among miners, when the end gate is swung from the top of the car, to prop up the gate with a pick, in the manner shown in the accompanying sketch. This is done whenever it is necessary to load the coal through the end of the car. The sharp points of the pick are forced into the ends of the boards forming the sides of the car and into the door, the weight of the door holding the pick in place while the loading of the car is in progress. The scheme is a very simple and practical one and is used by miners throughout the country wherever this type of car is employed in low seams.

A MINERS' TRICK

If desired, instead of depending on the use of a pick to support the door, in the manner I have mentioned, some may prefer to equip the door with a short iron rod attached to it by an eye-bolt. The end of the rod must be pointed like the sharp point of a pick, so that when the door is raised the pointed end will rest against the ends of the side boards of the car and be forced into it by the weight of the door, in the same manner as was the pick. If desired, two of these iron rods can be supplied, one on each side to better support the door.

When a car has been nearly loaded and the end gate is dropped into place and fastened it will not be possible to finish the loading, unless the clearance between the top of the car and the roof of the mine is sufficient to permit the coal to be shoveled over the sides of the car, or the end gate is hung lower than the sides for the same purpose. MINER.

Thomas, W. Va.

Transportation of Coal by Canal

Letter No. 3—I have read with interest W. W. Wotherspoon's reply to my recent letter regarding the cost of transportation on the New York Barge Canal, *Coal Age*, June 8, p. 1075, and am pleased to note that he admits that "if the canal system was constructed, owned and operated by a private corporation, undoubtedly, in computing the ton-mile transportation cost, all of the elements mentioned by Mr. Wilkins would be included."

Mr. Wotherspoon then goes on to explain that, under a provision in the constitution of the State of New York, no tolls can be collected on the canal and also that "as to the canals, their mere existence tends to hold in check and maintain a uniformity of rail rates in the territory between Chicago and New York City," and that "but for the existence of the canals, the rail rates between Chicago and New York and the rates made with relation to the Chicago-New York route would be materially higher."

Why Not a Government Railroad Instead of a Canal

The logical conclusion to the last statement would seem to me that, as a purely economic proposition, Mr. Wotherspoon should admit that it would have justified either the National or the New York State Government to build and maintain a railroad, including its terminals, between Buffalo and Albany, instead of the canal; and allow the shipper to own his own locomotives and freight cars, and run them over the government or state owned tracks, free of charge, in order to produce the result that he says the canal can accomplish, namely: "To hold in check and maintain a uniformity of rail rates in the territory between Chicago and New York City."

It would also seem that, as another economic proposition, the United States Government has no more or better ground for improving navigation by building and maintaining locks and dams on inland rivers and charging no tolls to the boat owners; nor the State of New York any greater facilities to build the Barge Canal and operate it free of all tolls, than for the National or State Government to build a railroad as suggested above and bear all the transportation costs, other than the cost of operating the trains.

In connection with the suggestion of the building of a railroad, instead of a canal between Albany and Buffalo, it may be stated that in 1905, the year construction work was started on the canal, Poor's Railroad Manual gives the cost per mile of the New York Central, including equipment, as $240,859, which for 296.52 miles, the distance from Albany to Buffalo, would amount to a total of $71,419,510, and for 438.72 miles, the distance from New York to Buffalo, the amount would be $105,669,660.

Mr. Travis, the New York State Controller, gives the cost of the Barge Canal to date as $233,695,351. It will thus be seen that the canal has already cost over three times what the New York Central Railroad between Albany and Buffalo had cost in 1905, and over twice the cost from New York to Buffalo, including equipment in both cases.

In view of these figures, does it not seem a rather peculiar solution of an economic problem, in order to maintain uniformity of rail rates, to construct a canal that has cost, including equipment, over three times the cost of a parallel railroad, including its equipment, and over twice that of the railroad from New York to Chicago?

The Question of Transportation Cost

Mr. Wotherspoon says in the last paragraph of his letter: "Since it is impossible to reduce to actual figures, the state-wide benefits received from the canal, I am not of the opinion that the construction, maintenance or interest charges should be considered in the computation of ten-mile transportation cost, but the actual boat operating cost alone should form the basis."

If this conclusion is economically sound, may I ask, Why not go a step further and say that in consideration of these state-wide benefits, the state should also own the boats and operate them free of any charges for carrying their freight, as well as to operate the canal and locks free of toll charges?

As an indication of what it has cost the State of New York during the construction of the Barge Canal, over and above the actual construction cost, the following statement by Eugene M. Travis, state controller, is interesting. He said in an article in the *New York Times*, May 12, 1918, "The total contribution to the canal debt sinking fund amounted to $62,896,702.66 from May, 1897, to May 1, 1918," which is a pretty large part of the state taxes to be set aside for the payment of canal bonds, before the canal is actually in operation, and for which the United States Government is going to provide the barges, because private capital has failed to build them.

Difficult to Estimate Cost of Operation

I am glad to note that Mr. Wotherspoon says with regard to the transportation cost per ton-mile on the New York Canal, "There is no accurate basis that could be employed in obtaining such cost. This is because no one has as yet had experience in navigating the new canal. * * * The actual cost may not be correctly ascertained until the transportation business has been developed."

In discussing the proposed Lake Erie and Ohio River Canal before the Engineers' Society of Western Pennsylvania, I said, "It is impossible for anyone to predict, before the canal is in operation, for what part of its round trip a boat will have a load of either coal or ore; or for what part of the trip the boat will have no cargo at all."

These two statements mean that, Mr. Wotherspoon and I agree that any estimates of unit-transportation costs on either the New York Barge Canal or the proposed Lake Erie and Ohio River Canal are at best only wild guesses and based on no reliable data.

Pittsburgh, Penn. W. G. WILKINS.

INQUIRIES OF GENERAL INTEREST

Sealing Off Fire on Intake

Kindly present the following question for discussion, in *Coal Age*, regarding the best method of extinguishing a fire that has gained so much headway on the intake of a pair of entries driven in solid coal, that it is thought best to seal off the fire by building an air-tight stoppings in each entry.

As shown in the accompanying sketch, the fire when discovered was located in the timbers and coal, about 30 or 40 yd. from the face of the intake heading. It may be assumed that both of these headings are generating

SHOWING LOCATION OF FIRE ON HEADING

but a small quantity of gas, so that it has not been necessary to use safety lamps in driving them. The size of the headings is 6 x 10 ft., and a good air current of 30,000 cu.ft. per min. is passing.

I want to ask three questions. Assuming that this fire is to be sealed off by building air-tight stoppings on both the intake and return airways, as stated: (1) How should this work be performed; or, in other words, in what order should the stoppings be built and the entries closed to the passage of air, to insure the greatest safety and avoid the danger of an explosion? (2) What would be the condition of the air on the inby end should the intake stopping be built and closed first? (3) What would be the condition of the air on the intake should the return airway be closed first.

I know that this question of the order of sealing off a mine fire has been frequently discussed in *Coal Age*, but I do not think that a fully satisfactory solution has been offered, and I believe nothing will be lost by a further discussion that may develop good practical ideas. It is not to be supposed that the same order of building the stoppings will apply in every case; but the conditions I have assumed are simple and should admit of but one solution and I hope there will be a good response from our experienced readers. ANCORA.

Edmonton, Alta., Canada.

It is the opinion of *Coal Age* that this correspondent is quite right in asking for a good discussion of the simple case he has assumed, and we agree with him that there is one way that will afford the greatest safety in the performance of the work. As we have frequently expressed our opinion on similar questions before, we leave the discussion of this question wholly to our practical readers, hoping that it may bring out, as our correspondent has stated, some valuable suggestions. It is one of the important questions in coal-mining practice on which opinions have always differed, chiefly because of the unfailing prejudices of mining men.

Auxiliary Power to Drive Fan

We have a 3 x 5-ft. Jeffrey fan, which is running continuously, 24 hr. a day. The fan is driven by a 75-hp. electric motor, running nearly under full load. It has frequently happened that we have been obliged to shut down the mine owing to a temporary failure in the power line. As this means a large loss in output and is extremely annoying, besides increasing the cost of operation, since the overhead charges and other unavoidable expenses continue unabated during the shutdown, it has been decided to install an auxiliary engine that can be used temporarily when the electric power fails.

Three types of engine have been submitted to us for our consideration; namely, engines operated by crude oil, gasoline and kerosene. As we are at a loss to decide which of these types is best adapted to our use and would prove most economical, we shall appreciate the suggestions of *Coal Age* and any of its readers who may have had a similar experience and can advise us as to what is the best means to adopt and where a suitable engine or motor can be secured. The engine must be capable of continuous service during the period when the supply of electrical power is cut off. It is only intended for use during such periods and the service is therefore intermittent, though liable to be required suddenly, at any moment of the day or night. The matter has been of such great importance to us, that I believe the subject is well worthy of discussion and hope to hear of the experiences of others along the same line.

Peoria, Ill. MINING ENGINEER.

The problem presented by this correspondent is a common one in coal-mining practice, and is, as has been stated, well worthy of discussion by those whose experiences have compelled them to adopt suitable remedies to protect themselves against loss arising from the failure of power lines.

In the opinion of *Coal Age*, the gasoline engine is the type of engine best adapted for use under the conditions named. Generally speaking, its construction is simpler and the engine more easily operated, requiring less skill and giving less trouble. All that is necessary is to keep the engine clean and in good condition and maintain a plentiful supply of gasoline ready for instant use when the emergency arises.

There are a number of manufacturers of good gas engines, among which we would recommend the Fairbanks, Morse & Co., Chicago, Ill.; Foss Gas Engine Co., Springfield, Ohio; Bessemer Gas Engine Co., Grove City, Penn. We shall be glad to have the suggestions and experiences of readers, who we hope will discuss the situation broadly as their practice may dictate.

EXAMINATION QUESTIONS

Tennessee Mine Foremen's Examination, 1918

(Selected Questions)

Ques.—How would you proceed with a mine fire in or near a heading, to insure the safety of employees?

Ans.—Without further information in regard to the arrangement of the mine, it is impossible to answer this question except in a general way. It is assumed that men are working in the heading and are in danger of being trapped by the fire. The first duty is to warn and withdraw these men by any way that is practicable. At the same time steps must be taken to get water to the fire. If the fire is on the intake, the men will be quickly warned of their danger by the smoke carried in on the air current, and they must be given every assistance possible to escape by a safe way. At the same time, an effort must be made to prevent the smoke and gases from the fire passing into the heading, if this is possible. The work of fighting the fire must be conducted on the intake side and performed only by experienced men.

Ques.—What is meant by a fault? Describe one you have seen.

Ans.—Correctly speaking, a fault is a dislocation of the strata caused by a slip of the formation along a line of fracture. In coal-mining practice, miners are apt to speak of any interruption in the continuity of a coal seam as a "fault," whether this occurs as a roll, a pinchout, or results from the erosion of a portion of the seam, by some agency, after its formation. Such interruptions in a coal seam are not, however, true faults, as there is no slip, resulting in an upward or downward throw of the strata along a line of fracture. The candidate must describe a fault he has seen, in his own words.

Ques.—An entry is driven S 60° E, while the rooms are driven N 85° E. The width of the rooms being 30 ft., find the distance on the entry, center to center of rooms.

Ans.—The question is incomplete, as the width of the pillar is not given. Assuming a 20-ft. pillar, the width of a room being 30 ft., the total distance between room centers measured across the rooms is 50 ft. In this case, the rooms make an angle with the entry of $180 - (60 + 85) = 35$ deg. The distance between room centers measured on the entry is, therefore, $50 \div \sin 35$ deg. $= 50 \div 0.57358 = 87.17$ ft.

Ques.—Explain the general arrangements of the ventilation of a mine, in the blowing- and exhaust-fan systems, and show how these differ from each other.

Ans.—In the blowing system, the ventilating fan is located at the mouth of the intake opening of the mine. The operation of a centrifugal fan draws the air in at its center and discharges it, at the circumference of the fan wheel, into a spiral casing by which it is conducted through the fan drift to the downcast shaft or intake opening of the mine. The pressure established by the action of the fan forces the air through the mine to the return opening where it is discharged into the atmosphere. In this system the mine is ventilated under a pressure greater than that of the atmosphere.

In the exhaust system of ventilation, the fan is located at the mouth of the return airway. The action of the fan, in this case, is the same as that in the blowing system, the air being drawn in at at its center and expelled at the circumference of the fan wheel. In the exhaust system, however, the fan drift, leading from the mine, is connected with the center openings of the fan and the spiral casing surrounding the fan wheel terminates in a chimney, by which the air is expelled into the atmosphere after passing through the fan.

In the exhaust system, the mine is ventilated under a pressure less than that of the atmosphere and the latter forces the air into and through the mine until it reaches the fan by which it is expelled into the atmosphere. It will be observed that the action of the fan, in both cases, is to create a depression at its center and a compression at its circumference, and the manner of its connection with the mine determines whether the fan is blowing air into or exhausting it from the mine.

Ques.—Give your opinion as to the advantage, if any, of a forcing fan over an exhaust fan, each working under the same conditions.

Ans.—These two types of fans are adapted to different gaseous conditions in the mine. An exhaust fan is generally preferred in the ventilation of a gassy mine, for the reason that this fan is located at the mouth of the return airway and does not interfere with the hoisting arrangements in the downcast shaft.

The haulage road of a gassy mine should be made the main intake airway, in order to avoid the danger of the ignition of the gas by the open lights of the drivers or motormen who cannot use safety lamps to advantage. The use of a force fan in ventilating a gassy mine, where haulage is performed on the intake, would necessitate doors being placed on the haulage road at the shaft bottom, which would impede the work of hauling the coal.

The use of a force or blowing fan is generally preferable in the ventilation of a nongassy mine, where it has been found of advantage to make the main haulage road the return airway of the mine. By doing this, the hoisting shaft becomes the upcast; and, not only is the formation of ice in the shaft, in winter, prevented by the warm return air current, but the dust of the haulage road is carried out of the mine and does not contaminate the intake air.

In blowing, the action of the fan is usually somewhat greater than when exhausting. In the former case, the fan is filled with the generally cooler outside air, which means a greater weight of air in revolution and a greater power developed.

COAL AND COKE NEWS

Harrisburg, Penn.

Despite extra efforts exerted by employers to safeguard employees, there is a steadily increasing number of fatalities in and about the coal mines, industrial plants and on public service lines of the State of Pennsylvania. From Jan. 1 to June 1, 1918, there were a total of 1245 fatal accidents in the three classifications, as against 1115 for the same period in 1917 and 946 in 1916. These were divided as follows: Mines, 461; industrials, 563; public service lines, 132. In 1916 fatalities were reported as follows: Mines, 437; industrials, 386; public service lines 123.

Deaths in and about the coal mines show an increase of 41 over 1917, while in industrials 45 less persons were killed this year than the year previous. Luzerne County leads the state in mine fatalities for the first five months of this year, with 100. Schuylkill and Fayette County are tied with 51, and Lackawanna had forty-six.

The state draft board authorities and officials of the coal companies face a perplexing question regarding the classification of men of draft age employed in and about the coal mines.

Coal companies also are experiencing difficulty in securing supplies. Quotations on mine supplies are next to impossible to get. It is also hard to secure cutting machines and other machinery needed in and about the mines. About the only way operators are able to secure equipment in a reasonable length of time is to obtain a priority order from the Government.

Every prospective purchaser of steam-generating equipment will be required to file with William Potter, Federal fuel administrator for Pennsylvania, a complete description of the machinery, together with the estimated daily fuel consumption, specifying whether anthracite, bituminous or oil will be used. This announcement was made during the week and is effective at once.

The fuel administration will take under consideration the probable effect of the proposed installation on the prosecution of the war and its relation to the available fuel supply. At the same time the estimated efficiency of such plants will be judged by the state advisory engineer before permission is given for installation to proceed.

J. J. Storrow, fuel administrator for New England, according to information reaching here, has won permission from Dr. Garfield to ship to New England 900 cars of bituminous daily from the coal fields of central Pennsylvania. This is a total of 45,000 tons a day, or almost 20 per cent. of the entire production of the soft coal fields in this state. Meanwhile, industries in the munition belt between this city and the Atlantic seaboard are clamoring for coal.

Charleston, W. Va.

The transportation situation in the Kanawha and Coal River districts in so far as it affected the coal industry last week was deplorable. Conditions were almost as bad as two months ago, when a number of mines were forced to shut down because of inadequate loading facilities. In fact, they were so bad last week that on Friday, for example, 33 mines were shut down, 20 of the mines unable to operate being the mines of the Cabin Creek Consolidated Collieries Co. The other mines were those of the Winifrede Coal Co., Carbon Fuel Co., Spruce River Coal Co., Ivy Branch Coal Co. and the East Bank Coal Co.

At a conservative estimate 80 per cent. of the mines were closed down last Friday, as well as on other days of the week, owing to an insufficient car supply throwing two or three thousand men out of work. Even at the beginning of last week conditions so clearly indicated what might be expected during the remainder of the week that Secretary Toomb, of the Kanawha Coal Shippers Association, sent a telegram to both Director Garfield and Director McAdoo in which he said: "Shortage last month from connecting railroads 2993 cars; shortage this month to date, 2174 cars, or 108,200 tons of equipment. Operators cannot hold men at this rate. Only 40 per cent, supply this month in Kanawha district, served by Chesapeake and Ohio Ry."

The Fuel Administration at Washington replied that the situation had been taken up vigorously with the Railroad Administration at Washington, but up to the end of the week, as already indicated, no relief from the shortage was given.

Discouraging conditions are also reflected in the production figures for the Kanawha district for the week ending June 8, only 144,646 tons being produced in that period. The total hours lost during the same period on account of car shortage was 2094, and because of labor shortage only 191, 2598 hours in all being lost. The labor situation in this district and in other districts of the state has been bad enough, but the absence of cars has made it infinitely worse. If no relief is afforded, coal miners will begin to leave the state in large numbers.

Aside from the territory in the Kanawha district served by the Chesapeake & Ohio Ry., the remainder of the Kanawha district served by the Kanawha & Michigan, and the Norfolk & Western field, the Guyan field, the Raleigh and New River fields appear to have been well supplied with cars this week. A strike in the Charleston yards of the Kanawha & Michigan Ry., Saturday morning, as a protest against the general yardmaster in charge there threatened, however, to tie up traffic on the Kanawha & Michigan and also to affect the interchange of cars to and from the Chesapeake & Ohio and the Coal & Coke railroads,, as well as to affect Government business, since the connecting roads mentioned have much freight for the Government powder plant at Nitro.

Conditions in the New River field, which have been so bad for the last fortnight, owing to an inadequate power supply, were much improved this week, the most gratifying feature of the situation there being a 100 per cent. car supply. This was directed by the Government authorities in order to meet the demand for navy and bunker coal. With cars available the mines in the New River district were able to materially increase their output.

Fairmont, W. Va.

The car supply in the Fairmont district (the Monongah division of the Baltimore & Ohio) has greatly overshadowed the labor supply recently, and with the scarcity of mine workers it has been found out of question to load all the cars coming into the region. D. R. Lawson, district representative of the Fuel Administration, who has his office at Fairmont, attributes the falling off of the car supply on Friday and Saturday of last week (the only light days in some time) to the submarine raiders. Boats did not make Curtis Bay or St. George on time, owing to the scare, which held up the loading of coal. Dumping started in earnest again Thursday of last week and the work has caught up Monday morning according to advices. All existing records for rapid loading were broken recently at Curtis Bay.

The car supply in the Fairmont district was good for the 19 working days from May 27 to June 17, averaging 1337 cars a day, which is in great contrast to the car supply from December to April when the average was 500 cars a day.

The 1769 cars in the Fairmont-Clarksburg region Monday were divided as follows: Coal 1769, coke 64, extra privately owned cars 55. A wreck on the Baltimore & Ohio near Clarksburg interfered with the Elliott mine getting its supply of cars Monday, the road being blocked.

Birmingham, Ala.

The Alabama mining district is in the grasp of a patriotic movement, and Sunday, at the principal mining centers, various speakers sought to impress on the workers the need of full coöperation in the Government program to increase the production of coal as a means toward winning the war. Meetings were held at Sayre, in the western part of Jefferson County, at Littleton and at Jones. Organizers Harrison, Prentice, Foster and Jones, of the United Mine Workers of America, and George Bondurant and P. H. Woodall, of the Four Minute Men, addressed the meetings. The miners were urged to work to their fullest ability and assist in the largest production throughout the coal district.

Increased output at mines is reported this week throughout the entire mining district of Alabama. There has been some sagging, but as a rule labor is putting forward its best effort and results show up most favorably as compared with the mine production 15 days ago. Production is 15 per cent. less than it could be if there was more effort given. Some of the mine employees charge the loss of production to the condition of mine and railroad facilities. However, the hope is expressed that before the end of the month the coal production will have taken on a big increase.

Toronto, Canada

Secretary W. M. Neal, of the Canadian Railway War Board, in a recent interview stated that it was impossible to exaggerate the gravity of the Western fuel situation. The movement of coal from the Western mines must increase at once if the people of the prairies are to have the means of keeping warm next winter. Canada's coal supply from American mines will be curtailed this year, and the West will find itself compelled to use Western coal. This must be ordered now and moved now, as in the fall every eastbound car from the foot of the Rockies to Winnipeg will be required for crop movement. The railways, under the direction of the Canadian Railway War Board, are prepared to move the greater part of next winter's supply before October, but the mines are only loading a fraction of the supply of cars available for them. Good explanations are offered. In one case the mine is unable to load cars on account of labor troubles, in another the mines are not receiving orders from the Western dealers. But whatever the reason may be, a solution must be found promptly. Last winter the railways were able to help out the public by supplying coal from their own reserves. Next winter this will not be possible, the reserves being depleted. Some towns are getting together to finance next winter's fuel bill for their people, and some of the mines are taking special measures to increase production and loading. These examples must be followed and enlarged upon if the West is to be saved from distress if not disaster, next winter.

PENNSYLVANIA

Anthracite

Shamokin—The yards of the Philadelphia & Reading Coal and Iron Co., at Newberry Junction, are choked with shipments of coal, and overhead docks are being built to expedite the work of coal engines engaged in moving the fuel.

Lansford—Three men were killed and two were seriously injured in the Lehigh Coal and Navigation Co.'s No. 4 mine on June 15. The men were engaged in timbering a turnout in the gangway when the top gave away, burying them beneath the mass.

Edwardsville—Charged with uttering disloyal remarks against the United States Government and the American Red Cross, Jacob Stanick, an Austrian, who gave his age as 25, was arrested on June 14 at one of the Delaware & Hudson collieries by special detectives of the company. He is now in the Lackawanna County jail, in default of $1000 bail.

Pittston—The men engaged at the Pickaway colliery of the Quinn Coal Co. held flag-raising exercises on June 14, and with the workmen and residents nearby a large crowd was present. In the various drives for the Third Liberty Loan and the Red Cross all the miners contributed a day's wages, placing the large plant in the 100 per cent. class.

Oneida—Mrs. Apolonia Ambrose has been awarded a total of $1328.50 for the death of her husband, who was employed by the Lehigh Valley Coal Co. He had his foot cut while at work and it caused a pre-existing tubercular condition of the lungs

to be aggravated. This award by the Compensation Board sets a new precedent, as it gives an award in a case where an injury caused an old ailment to be aggravated.

Kingston—Under the direction of F. E. Zerbey, general manager of the Kingston Coal Co., a sawmill was erected some time ago at No. 4 colliery, and systematic collection and cutting of waste wood was instituted. The result was the speedy accumulation of a large wood pile. The miners were quick to take advantage of the company's offer to sell this wood at cost. So far as is known, the Kingston Coal Co. is the first to inaugurate systematic use of waste wood.

Lavelle—An attempt of the Schuykill Coal Co. to obtain a right-of-way through the farm of George Mather met with legal resistance on June 13. The right-of-way extended through a field of oats, and Mather and his friends were guarding it with shotguns when Mather was called away. During his absence workingmen of the coal company entered the land and erected piers for an overhead railway to be used for the transportation of culm. Judge Bechtel granted a preliminary injunction against the company.

Old Forge—Edmund B. Jermyn and Joseph J. Jermyn have secured from the Lehigh Valley Coal Co. the culm pile at the old Sibley mine and will at once begin preparations for washing the coal and putting it on the market. With this end in view an application will be made on July 5 for a charter for the Dennington Coal Co. The bank is estimated to contain about 250,000 tons of coal. Some time ago the Lehigh Valley Coal Co. sold the remaining coal at the Sibley to the Pennsylvania Coal Co., and the coal mined in the Sibley workings is taken underground to the Pennsylvania's Old Forge colliery. After the coal was sold the Sibley washery and breaker was dismantled, and the company now has no means at hand of screening this coal unless a washery is erected. The Jermyns, who have acquired the dump, have a washery at their colliery, which is a few hundred feet from the dump just acquired.

Bituminous

Chambersville—Eliza J. Smith and brothers, operating the Peterman mine here have ten houses under course of construction for the use of their miners. This mine is a new operation, but the production has increased so rapidly that it has been necessary to make further provisions for the workmen.

Lovejoy—The Estep Brothers Coal Mining Co. has installed electrical power in its mine here. Electric locomotives, compressors, pumps, etc., are now in operation and the production has been increased greatly. A new drift mine is being opened near the present mine and the coal will be all loaded over the same tipple.

Butler—The Brewster mines of the Big Creek Coal Mining Co. at Wahlville, near here, are now electrically equipped. The power was turned for the first time one day last week and everything went off without a hitch. Electric mining machines, pumps and motors have been installed. It will increase the production more than four times what it has been in the past.

Johnstown—T. Stanton Davis, representing a syndicate of Cambria County coal operators, has purchased 4200 acres of coal land in the vicinity of Cambria township, the consideration being in the neighborhood of $850,000. The new field is in the vicinity of Ebensburg, the county seat of Cambria County, and a new town is to be developed there and called "Hart-Bee." Branches of the Pennsylvania and New York Central railroads are to be built into the new town.

Locust—The Locust Colliery Co., controlled by James Pierpont & Sons, of Philadelphia, is making many improvements to its new mine here. A new shop and power plant is being erected and machinery installed, the side tracks are being lengthened to provide for the increased tonnage and several houses are being built for the workmen. The new houses are the same type as was erected last year and provide comfortable and improved quarters for the miners, which Mr. Pierpont believes one of the essentials in keeping good men.

Pittsburgh—The Agricultural Department of the State of Pennsylvania, and the same department of the United States, have sent experts to western Pennsylvania to make tests with the lands which are being destroyed for agricultural purposes by the coal-stripping process, with a view of reclaiming the lands and putting them back into a condition which would again permit them to be farmed. The largest stripping operations of this district are in Washington County, and it is here that tests are being made. If successful it will reclaim hundreds of acres that would otherwise be useless after the coal has been excavated.

WEST VIRGINIA

Thurmond—The Clay Coal Co., of Thayer, of which C. M. Holliday is president, is erecting a new bin for smithing coal at its Ridgeview mine.

Harwood—A mine is being opened between Harwood and Shinnston by the New Superior Coal Co., and a new tipple is under construction. The company, which owns about 66 acres of coal land, plans to begin producing coal by July 15.

Huntington—As soon as a sidetrack from the Chesapeake & Ohio is put in, the Weewin Coal Co. on Arbuckle Creek will begin to ship coal, the plant being ready to operate as soon as transportation facilities are provided.

Phil C. Jack and others, of this city, have purchased the plant of the Glen Elk Coal Co. on the Kanawha & West Virginia Railway.

Charleston—The Mordue Collieries Co. expects to be able to begin shipping coal from its mines on Coal River in July.

The Boone County Coal Corporation has purchased from Paul Hardy and associates the Dobra mine on Coal River, from the Coal River Coal and Coke Co., this mine having a drift opening and a 5-ft. seam. With purchases recently made the Boone corporation now owns about 20,000 acres of coal land and is operating 12 mines producing about 40,000 tons of coal a month.

Mabie—Plans are being made by the Randolph Smokeless Coal Co. to build a plant near Mabie, in Randolph County, to cost approximately $100,000, covering electrical equipment, an incline leading to the mine or mines, etc. Engineers are now at work with a view to preparing specifications of what is needed. The coal will be reached by a drift mine. The organization of the company has been perfected by the election of A. F. Bennett as president; W. T. George as vice president; R. E. Talbott as treasurer and H. J. Wilcox as secretary. All the officers reside at Philippi.

NORTH CAROLINA

Cumnock—The Cumnock Coal Co. is building 20 new houses for its employees. The houses will be equipped with water and sewer conveniences, and will be modern in every respect. The company has completed a new tipple and will soon be taking out coal from the old shaft. At present two or three cars a week are coming out from the air shaft. The workings will soon be in shape to begin mining on a commercial scale, although the coal will not go into the market, as it will be used by the engines of the Norfolk Southern road. The Carolina Coal Co. on an adjoining property, is in about 5 ft. of nice, clean coal, and expects to be taking out coal for the local market in a few days. Analyses of these coals show a high volatile content, low sulphur and low ash.

KENTUCKY

Madisonville—The Memphis Coal Co. will shortly erect a steel tipple at Mannington, Ky., where the company has purchased the Lamb and Franklin mines, and plans opening a third mine. It intends to handle the output of the three mines over the one tipple.

OHIO

Zanesville—Fire, thought to have been of incendiary origin, destroyed the Pennsylvania R.R. trestle on the spur to the Monitor mine at Darlington recently. The Monitor mine is operated by the Burton-Townsend Brick Co. The loss from the fire falls on the railroad, which will rush the repair work.

New Lexington—Stripping operations in this vicinity are reaching considerable proportions, one company having just started work on a tract of 250 acres bearing a five-foot vein close to the surface. Stripping is expected to cut a larger figure in the production of coal this year than ever before, on account of the volume which can be produced at small expense and the need for increased production.

INDIANA

Brazil—Coal miners of Brazil, Knightstown and Harmony have called meetings for the purpose of framing a petition to submit to Director-General McAdoo asking that the miners' train on the Pennsylvania be placed back in service in order to transport the miners to and from work. They assert that such a move would increase the output of coal.

Hammond—Fires have been lighted in the first of the new openhearth furnaces of the $25,000,000 steel works of the Mark Manufacturing Co. at Indiana Harbor. Production of steel is expected in two weeks. The company has four rolling mills in operation producing plates. The new openhearth operation will be followed by the blowing in of a blast furnace, the first of several new ones to be built and the largest in the Calumet region of Chicago.

ILLINOIS

Pana—Harry Turner, who recently purchased 83 acres of the Hayward tract of land adjoining Pana, has sold the coal rights for $30 an acre.

Dawson—The Dawson coal mine has been sold by Mr. and Mrs. Edgar H. Buckley, of Bloomington, Ill., to L. E. Fischer, formerly general manager of the Illinois Traction System. The consideration is said to have been $100,000.

Bloomington—An appropriate flag-raising was enjoyed by miners of the McLean County Coal Co. on June 14. Addresses were made by Mayor E. E. Jones and Spencer Ewing, and community singing was a feature of the event. An 8-ft. flag was raised from the top of the shaft.

Hillsboro—The 325 members of Taylor Springs local, United Mine Workers, have voted to give $1 per month from their pay to the Red Cross for the duration of the war. This will amount to more than $4000 for the next year, beginning June 1, and this rate will be maintained as long as the war lasts.

O'Fallon — The following St. Clair County mines have been awarded Liberty Loan flags for going over the top with 100 per cent. of their employees as purchasers of the Third Liberty Bonds: Nigger Hollow No. 1, 301; Nigger Hollow No. 2, 590; Avery, 105; Shiloh, 392; Prairie, 300; Radium, 115; Little Oak, 298; Superior, 137; Muren, 144; Columbia, 114.

Marion—A new town is being built in the eastern portion of the county. It is three miles east of Pittsburgh and will be known as Paulton, on an extension of the Marion & Eastern R. R. A new mine is being sunk there by the Ernest Coal Co., which is controlled by Cosgrove & Co. of Johnstown, Penn. This new mine is going down on the 4500-acre tract and will be one of the largest mines in southern Illinois when finished. It is understood that the new town will be named after Paul Cosgrove, who died a few months ago and who was in charge of Cosgrove & Co.'s interests in the west.

Belleville—The question of whether the exigencies of war justify violation of mining laws is raised in an injunction suit that has been brought in the St. Clair County Circuit Court by the Signal Hill Coal Co. against Thomas C. Wright, state mine inspector, to enjoin him from keeping the company's mine shut down on account of the escapement shaft being less than 250 ft. from the main shaft. The company says in its petition that it operated before the law was enacted, with the shafts nearer than 250 ft. apart, and it is contended that the mine should be permitted to continue operating because of the critical shortage of coal. Arguments will be heard in a few days.

Harrisburg—The Wasson Coal Co., one of the big producers in Saline County, has filed suit against the Central Illinois Public Service Co. for $125,000 and another suit for $175,000 against the Southern Illinois Railroad and Power Co., which is a successor to the first mentioned defendant. The suits are based on the alleged failure on the part of the light companies to carry out the stipulations in a contract for power. During the past winter the mines depended upon the power companies and were shut down many times on account of no electricity. Many other mining companies in the southern Illinois field have contracts which have cost them enormous sums in idle times during the past winter.

Foreign News

Edmonton, Alta.—John T. Stirling, fuel administrator for Alberta, states that fuel orders are coming in satisfactorily from Winnipeg. There were on an average 1200 tons a day being shipped from the Drumheller mines to Manitoba, and the amount was steadily increasing.

Medicine Hat, Alta.—Work on the development of the Ainsley coal mine near Medicine Hat is scheduled to commence at once, and it is reported the daily output will be 1000 tons. The mine will employ

200 men. A spur track is to be built from Medicine Hat to the mine. The Ainsley mine was only a small enterprise before being taken over by an American financier.

Edmonton, Alta.—The provincial government is arranging a system of inspection for all cars of coal shipped out of the province. This is being done to remedy the complaint coming from the Winnipeg market that dirty coal is being shipped out. In order to hold the outside market the best grades of coal only will be shipped to the other provinces, and the softer grades used nearer home.

Winnipeg, Man.—Demonstrations showing how to use western Canadian coal to the best advantage were held for ten days commencing June 6 and were attended by hundreds daily. About a dozen hot-air and hot-water furnaces, ranges and stoves were in operation, with A. E. Wilson of Drumheller, Alta., acting as demonstrator. Printed instructions as to how to burn Alberta coal in the ordinary stoves and furnaces were distributed.

Personals

G. H. Marting, formerly mine manager for the Whitaker-Glessner Co.'s mines, is now managing the Milburn Byproduct Coal Co. at Milburn, W. Va. The company is owned by the Citizens Gas Co., of Indianapolis.

John T. Lewis, of Johnstown, Penn., has been appointed by Seward E. Button, chief of the Department of Mines of Pennsylvania, as inspector in the Twelfth Bituminous District, and will have headquarters at Punxsutawney. He assumed his duties on June 20.

George R. Henderson, of Philadelphia, Penn., has been appointed federal administrative engineer for Pennsylvania. Mr. Henderson has assumed his office and will supervise the inspection, survey and investigation of boiler houses and power houses in all plants in Pennsylvania outside of the Pittsburgh district.

Obituary

W. A. McCloud, one of the first men to develop the Linton, Ind., coal field, died at his home, 918 Fairfield Ave., Indianapolis, Ind., June 12. While superintending a mine in Clay County, Indiana, last July, he fell from a coal car, receiving injuries which had confined him to his room since and which gradually led up to his death. He was 65 years of age.

Industrial News

Hazard, Ky.—The Bewley-Darst Coal Mining Co., Hazard, Ky., has purchased the Coneva plant,, near Hazard, and plans expenditures of several thousand dollars in improvements and equipment.

Louisville, Ky.—According to unconfirmed reports, the Kentucky River Power Co., Hazard, Ky., is planning construction of 25-mile transmission line to furnish power to a number of coal mines operating in the district.

Bee Pee, Ky.—The Williams Byproduct Coal Co., J. W. Williams, president, Fountain City, Tenn., has purchased machinery for developing 1500 acres of land, for daily output of 1500 tons. Will spend about $150,000 on equipment.

Kimbolton, Ohio—The Kimbolton Coal Mining Co. is opening a new slope mine at this place, Willis E. Holloway Co., of Cleveland, Ohio, being the engineers and contractors. The tipple is designed to produce 2000 tons per day of No. 8 Ohio coal.

Reedsville, Ky.—The John Runs Coal Co., S. M. Bradley, of Morehead, president, recently increased its capital from $15,000 to $30,000, and will develop 2000 acres of land, planning an output of two cars at start. The company may later install machinery.

New York, N. Y.—E. Kelly Downey has been elected a director of the Wholesale Coal Trade Association of New York, to fill the vacancy caused by the resignation of W. R. Coyle, who has reëntered the military service as a captain in the Marine Corps.

Wheeling, W. Va.—Contracts have been let by the Bertram Coal Mining Co., of Wheeling, to the Willis E. Holloway Co., of Cleveland, Ohio, for the work in connection with its stripping property at Romaine, Ohio. The property is to produce 3000 tons per day

Star Hill, Ky.—The Star Hill Coal Co., recently organized, plans a small development on 135 acres of coal land, and will install mining machinery. E. W. Roach is president and manager, J. B. Rogers, vice-president and G. W. Nicholson, secretary-treasurer.

Charleston, W. Va.—The Brick Coal Mining Co. has been formed to operate mines in Upshur and Harrison Counties, the authorized capital stock being $100,000. The incorporators are J. Kandt, of Detroit, Mich.; D. J. Carter, Harry W. Sheets, B. B. Jarvis and C. D. Duthie, of Clarksburg, W. Va.

Paducah, Ky.—The Columbia-Panama Coal Co., H. H. Hardringe, Chicago, president; W. A. Calhoun, Paducah, chief engineer, plans development of 2000 acres of coal land on Cumberland & Manchester R. R., at Goose Rock. Has asked for prices on mining equipment, plans mining town, tramway, etc.

Morgantown, W. Va.—H. C. Greer, Albert Shuman, C. E. Watson, J. L. Hatfield, all of Morgantown; and J. P. Burbridge, of Dillslow, W. Va., are the incorporators of the Burbridge Coal Co., which has been incorporated with an authorized capital of $5000 to operate mines in Monongalia County, West Virginia.

Charleston, W. Va.—Among the new coal companies organized last week was the Guy Pocahontas Coal Co. of War, McDowell County, West Virginia, incorporated with a capital stock of $5000, the incorporators being W. M. Guy, S. E. Massey and Eulalia Little Guy, all of Bramwell, W. Va.; J. W. Johnson and V. T. Stricklen, both of War, W. Va.

Morgantown, W. Va.—The application of the Monongahela Railway Co. for permission to build a line along Scott's Run from the Monongahela River to Cassville, in order to accommodate mines at that place, has been denied. The application was opposed by the Morgantown & Wheeling R. R. on the ground that the proposed extension would parallel its own line.

Charleston, W. Va.—H. P. Brydon and brothers have secured a charter for H. P. Brydon & Bro., Inc., the company to operate coal lands and operate a supply depot for miners. The company is capitalized at $50,000 with the following as incorporators: H. P. Brydon and T. F. Shaffer, both of Cumberland; E. R. Brydon and S. B. Brydon, of Bloomington; Ned and Edward James, of Piedmont.

Columbus, Ohio—A flag-raising ceremony was held June 14 at practically every coal mine in the Buckeye State. Arrangements were made by the mine owners, state officials and Secretary W. D. McKinney, of the Southern Ohio Coal Exchange. The ceremonies consisted largely of patriotic songs, speeches, and the raising of the American flag. Practically every available large American flag in Columbus was purchased for the occasion.

Buffalo, N. Y.—W. C. Blodgett, Buffalo representative of Dickson & Eddy, has been appointed collector of statistics of anthracite shipments by lake for the lower lake ports, by the anthracite commission now sitting in Philadelphia. All shipping agents report to him daily the amount of coal loaded, also destination and consignee. He has long been acquainted with this work The former connection will be maintained, with the Buffalo office as headquarters.

Toledo, Ohio—More activity in lake shipments is shown by the reports of loadings at the Toledo & Ohio Central and Hocking Valley docks during the week ending June 15. During the week the Hocking Valley docks loaded 160,713 tons as compared with 11,744 tons the previous week, making a total of 892,293 tons for the season. The Toledo & Ohio Central docks loaded 79,000 tons compared with 7000 tons the previous week, making a total of 484,000 tons for the season.

Columbus, Ohio—Double-tracking, the building of new yards and the enlargement of present ones, the construction of a 15-stall roundhouse at Galion, and other improvements on the Big Four, requiring an expenditure of approximately $10,000,000, for the purpose of bettering and facilitating the movement of troops, munitions and coal for the winning of the war, were announced by Chief Engineer C. A. Paquette. The plans provide for double-tracking 58 miles of the Columbus-Indianapolis division and 38 miles of the Chicago division.

Bradshaw, W. Va.—The Bradshaw Coal Co., Bluefield, W. Va., organized by Edwin Mann, president; George S. Strader, secretary-treasurer, of Bluefield, W. Va.; Robert J. Hancock, Lynchburg, Va., vice-president; C. L. Biddilson, War Eagle, W. Va., engineer, has purchased the holdings of the Bradshaw-Pocahontas Coal Co. in McDowell County and plans improvements costing $75,000. Electricity will be purchased from the Appalachian Power Co., Bluefield, W. Va. The company was recently incorporated with capital of $300,000 at Lynchburg.

Buffalo, N. Y.—The supply of coke is only fair, and consumers are doing all they can to get a regular connection with some byproduct plant building their own where possible, as it appears to be more economical to obtain the coke in that way where all the products are made use of. Development of the byproduct plant projected by the Buffalo Union and Donner companies in Buffalo has not begun yet, as it is hard to get men and material for the work. Beehive coke is bought of producers direct, and no prices are made here. Receipts of iron ore by lake for the week were 248,604 gross tons.

Cleveland, Ohio—Eastern Ohio operators are protesting against the alleged discriminatory distribution of coal cars in the eastern Ohio district as compared with certain parts of West Virginia. A statement issued recently shows that the car supply on the Wheeling division of the Baltimore & Ohio during the month ending June 15 was only 40 per cent of requirements, and that fully one-third was taken for railroad fuel, leaving only a small number of cars for the lake trade and to fill commercial contracts. It is also claimed on the Monongah division that operators are given approximately 100 per cent. car supply. Efforts have been made to call attention to this discrimination to the proper authorities, but without results. In the meantime eastern Ohio operators see their miners leaving for other fields or to enter steel and iron plants because of lack of work.

St. Louis, Mo.—Creation of a new railroad operating region west of the Mississippi River, to include the southwestern lines, with headquarters of the regional director at St. Louis, is the culmination of months of effort directed by the St. Louis Chamber of Commerce, with the purpose of having this district separated from the territory under the jurisdiction of R. H. Aishton, regional director of Chicago. It is the belief here that the action taken by the Government will greatly facilitate transportation matters in this district. Benjamin F. Bush, president of the Missouri Pacific Railroad Co., has been appointed regional director for the southwestern railroad division and has resigned the railroad presidency to take the position. The territory west of the Mississippi River is now divided into three districts, with Aishton directing the Chicago division, Bush the southwestern division and Hale Holden, president of the Burlington R.R., directing the central division.

Newark, N. J.—United States Attorney Lynch ordered a coal company to remove from the summer home of Forrest F. Dryden president of the Prudential Life Insurance Co., at Bernardsville, 56 of the 235 tons of coal it had delivered there. In his application for the coal Mr. Dryden explained that while last winter he had used only 195 tons, new buildings had been completed since then which would require a greater supply of coal next winter. He will have in his bins, when Mr. Lynch's order has been carried out, only two-thirds of the supply that he deemed necessary.

Louisville, Ky.—Coal rates in Kentucky will not be increased 15c. a ton over what they were on June 1, 1917, before adding the increase of 25 per cent. authorized by General Order No. 25, Railroad Administration. This was the contention made by the coal men at a hearing ten days ago, when a protest was launched against a 25 per cent. increase on top of the proposed increase of 15c. a ton, which had been accepted.

St. Louis, Mo.—The Interstate Commerce Commission hearing on the petition of the St. Louis Chamber of Commerce for the abolition of the bridge arbitrary of 20c. per ton on coal, which had been in progress two weeks, adjourned Friday, June 14, to July 9. The petitioners have finished their side of the case and several witnesses have been heard for the defense. The adjournment was necessitated by Commissioner Mackley having to return to Washington. It is expected that several more days will be needed to complete the hearing. The commissioner will then make his report to the commission. Attorneys for the Terminal Railway Association and the railroads will ask the commission to throw the case out on the ground that Director-General McAdoo's order increasing all freight rates directed that all existing differentials be preserved. Attorneys for the petitioners will contend that under the act creating the railroad administration authority to pass upon complaints was reserved to the commission.

MARKET DEPARTMENT

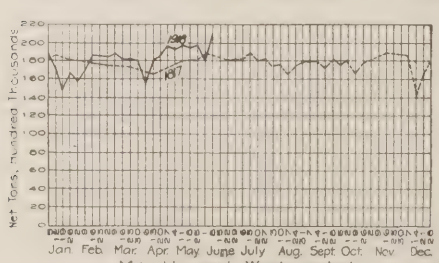
Weekly Review

Record Output of Bituminous Brings Feeling of Optimism—Anthracite Production About Normal—Car Shortage Gives Way to Scarcity of Labor—Bureau of Production to Speed Up Mines—New England Shipments Large—No New Industries for Atlantic Seaboard—Market Conditions Active

A FEELING of optimism is engendered by the record production of bituminous coal during the week ended June 8, when the output of soft coal reached the unprecedented total of 12,465,000 short tons. This exceeds by 1,691,000 short tons the production of the preceding week. The average daily output was well above 2,000,000 short tons, which amount of coal must be shipped every working day for the rest of the coal year if estimated demands are to be met. It must be remembered, also, that to date we are behind considerably more than 26,000,000 short tons of bituminous coal. Shipments of anthracite for the week ended June 8 totalled 40,754 cars, which is about normal output for the hard-coal mines under the existing labor conditions.

Though the shortage of cars continues to act as a bar to the greater production of bituminous coal, particularly in West Virginia, this condition is being alleviated rapidly. There is promise that ere long the most important producing sections will be receiving close to 100 per cent. car allotment. The laying of the car-supply ghost, however, has seen the rise of another to haunt the coal operator. This time it is labor shortage, a factor which bids fair to become the chief deterring reason to maximum output.

Realizing that labor in the coal mines must be inspired to do its best, James B. Neale, who heads the newly formed Production Bureau of the Federal Fuel Administration, is planning a nation-wide campaign to speed up coal production. The workers at the mines are to be addressed by well-known men, and the operators will be urged to do their utmost to expedite production by providing every facility and convenience which will aid the employees to mine more coal.



After a careful study of New England's requirements, the Fuel Administration apportioned 30,000,000 short tons of bituminous coal to that section. Steps have been taken to insure the delivery of 60 per cent. of the total amount by Oct. 1. To do this it will be necessary to ship considerable coal to New England during the next three months, as forwardings in April and May were below the average which should have been maintained. Mines in Central Pennsylvania have been ordered to ship to New England 45,000 tons a day, or almost 20 per cent. of the entire production of the soft coal mines of Pennsylvania.

Industrial development in the East and in New England having reached the point where it is no longer feasible to permit the erection of new plants and factories, further industrial expansion in these sections has been prohibited by joint action of the War Industries Board and the Fuel Administration. The order is intended to force new industrial activities in districts where fuel and raw materials can be transported over lines that are not congested. The restricted area consists of the New England States; eastern and southern New York; Pennsylvania, as far west as Williamsport and Altoona; all of New Jersey, and Delaware and eastern Maryland, not including Baltimore.

Market conditions are quite active. The sharp demand for domestic and steam grades continues, and the storing of domestic coal is going on at a good rate. However, receipts by dealers are not half the tonnage desired.

COAL PRODUCTION

Bituminous coal production during the week ended June 8 was the largest in history. The soft coal produced (including lignite and that made into coke) is estimated at 12,465,000 net tons, an increase over the week of June 1 of approximately 1,900,000 net tons, or 17.8 per cent., and the same increase over the week of June 8, 1917. The average daily production is estimated at 2,077,000 net tons, considerably in excess of the 1,791,000 net tons during the week

preceding and 1,789,000 net tons during the same week of the preceding year. Anthracite shipments during the week ended June 8 were 40,754 cars, an increase of approximately 9000 carloads, or 28.3 per cent., over June 1.

Beehive Coke—Production of beehive coke in the United States during the week ended June 8 is estimated at 638,000 net tons, an increase over the week preceding of 26,000 net tons, or 4 per cent. The average production per working day amounted to 106,000 net tons as compared with 102,000 net tons during the week of June 1. The principal operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania produced 362,075 net tons of coke during the week ended June 8, or 77.2 per cent. of their present capacity compared with 75.6 per cent. during the week ended June 1. Of the factors limiting production, amounting to 22.8 per cent. of present capacity, 0.5 per cent. is due to shortage of coke cars, 18.3 per cent. is attributed to insufficient yard labor, 0.2 per cent. to plant disability and 3.8 per cent. to all other causes. The same operators produced 161,400 net tons of coal.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended May 18	May 25	June 1	June 8
Bituminous shipments, 123 roads	205,026	207,036	188,318*	220,607†
Anthracite shipments, 9 roads	41,011	40,594	31,762*	40,754†

* Revised from last report. † Subject to revision.

Byproduct Coke—Operating conditions in the byproduct industry improved during the week ended June 8, causing slight increase in production. The plants of the country operated at 88.3 per cent. of their present capacity as compared with 87.7 per cent. the week preceding. Of the total losses of 11.7 per cent., 2.7 per cent. was attributed to lack of coal, 3 per cent. to labor shortage, 5.1 per cent. to repairs to plants, 0.2 per cent. to "no market" and 0.7 per cent. to all other causes. Material improvement was reported by operators in Maryland and Ohio, production by the operators in the former state rising from 98.7 per cent. to 100 per cent., and in the latter state from 94.5 per cent. to 96.7 per cent. Lack of byproduct coal caused the operators in Tennessee to report the ratio of production to present capacity at 62.7 per cent. Labor shortage and plant repairing in Pennsylvania continue to be the factors limiting production, thereby causing Pennsylvania operators to report the lowest ratio of the large producing states—73 per cent. of present capacity. "No market" losses in Minnesota declined sharply during the week ended June 8—from 9.3 per cent. to 5.4 per cent.

BUSINESS OPINIONS

Dry Goods Economist—Early this week the announcement was made that the War Industries Board had determined to stabilize the prices asked for cotton fabrics and had called upon leading cotton goods manufacturers and distributors to name the prices that should be asked for various grades of cotton goods and to explain the basis on which the prices suggested had been determined. Manufacturers, converters, wholesalers, retailers and even consumers are affected by this action of the War Industries Board, since in the future all will be called upon to pay for cotton goods on the basis of the prices to be determined by the Board. Even contracts already entered into will be subject to revision if the goods they call for are delivered later than certain specified dates.

Bradstreet's—In its broadest respect, business in general eclipses that of this time last year, but of course the largest single disburser is the government, its daily expenditures now averaging about $57,000,000. In ordinary channels business is getting closer to a cash basis, and naturally so, for such sellers as have goods available are in a position to make terms as well as to select customers. Jewelry, liquors, beer, ordinary building and other so-called less essentials are in the doldrums, as it were, and liquor dealers are going out of business.

Marshall Field & Co.—Current wholesale distribution of dry goods has been very

much in excess of the large shipments during the corresponding period a year ago. Road sales for the week for immediate and future delivery show a splendid increase over those of the same week in 1917. Customers have not been in to market in such large numbers as last year. Collections show a good increase over those of the corresponding week a year ago. The cotton goods market is firm.

Atlantic Seaboard

BOSTON

More hopeful outlook for New England due to Mr. Storrow's success at Washington. New plan now assumed to be in operation, but it will be some weeks before anything like maximum movement is realized. Query whether present plan will increase number of contracts with operators for consignment to this territory. Opinion is that producers will continue shy of commitments. Great interest in actual working out of distribution program. Multiplicity of reports, etc., is to its disadvantage, but local policing is the more sensible method. The main thing is for this territory to get its quota now when the railroads can haul the coal. Slow movement coastwise means a considerable loss in receipts. Hampton Roads dumpings decrease due to fewer arrivals of tonnage and the consequent diversion of shipments from tidewater to line and connecting railroad points.

Bituminous—June 10 was a favorable day for New England. The fuel authorities at Washington ordered certain district representatives to make up the quota for this territory all-rail by instructing operators to consign 100 per cent. on such contracts or orders as were on hand, and in addition to that volume of coal to send forward to the New England gateways enough more each week to bring consignments all-rail up to the full New England ratable proportion. In central Pennsylvania this would amount to 4500 cars weekly, based on current output. At the conference in Boston on June 4 on the "zoning" problem, it was shown by representatives of the New England railroads that the latter could easily handle 450 carloads more per day. This was brought to the attention of Mr. Garfield and the Railroad Administration with such force by Mr. Storrow and others interested in the New England situation that the whole New England program has been rearranged, so far as concerns all-rail deliveries. It has been understood that during May, for instance, all-rail consignments into New England from central Pennsylvania amount to only about 1700 cars weekly. The new order therefore calls for 2800 cars more from that one district, but this does not look so heavy as it might for the reason that the same readjustment of program provides that coal which formerly moved into New England from the Somerset, upper Potomac and Fairmont districts, which moved into New England all-rail, has been shut off upon the understanding that such coal will reach Providence or Boston via Curtis Bay or Port Covington piers at Baltimore.

The result of these broad instructions has been the cancellation of all directions to district representatives to ship only to preferred requirements. It is an important part of the plan that the policing is to be done by state administrators, and it will be the function of Mr. Storrow's office not only to regulate the flow of coal to all grades and kinds of consumers, but through the district representatives to put each buyer who has no contract in touch with an operator who will be in position to supply him, always bearing in mind that when production falls off then New England's volume of coal likewise drops down.

There are going to be enough problems involved in the operation of this plan, but obvious though some of them are, and large as the job is, it is much more feasible for an office like Mr. Storrow's, with representatives in every part of New England, to control it either at the gateways or at destination than to have the same thing attempted from Washington or by the district representatives. Any sag between the volume of coal covered by contracts in hand and the 4500 cars weekly is to be destined according to orders from Mr. Storrow, and to this end a considerable number of destinations have been furnished the Altoona office. The 4500 cars are to include railroad fuel as well, and it is expected a real effort will be made to build up stocks of locomotive coal. The whole program is subject to orders from Washington, and any day there may be heavy inroads on the New England quota to make up deficiencies from other districts. However, it is a real move in favor of coal for New England and comes as a decided relief after the alarming slump in receipts all-rail that was disclosed during May.

The fact that from Washington it is insisted that requirements be classified and tabulated in such way as to show in detail the course of each requirement only adds to the machinery of operation, but those who formulated the system have good courage and everybody wishes them well. The big thing is to get coal forward in due proportion during the months when the railroads are in position to handle it. Losses in movement during favorable weather are never made up later in the season.

While traffic is relatively light on the New England lines the question of car-miles is not so important, and for that reason any "zoning" of consuming territory is likely to be postponed. Without doubt it will come up prominently when there is any sign of congestion, and at that time the plan outlined at the June 4 conference will probably be carried out. It was agreed there should be a 30-day notice in order to give consumers a chance to adjust their contracts. As it is, the embargo of all-rail coal via Shippensburg is causing uneasiness to a good many consumers who for years have drawn their supply from territory tributary to the Baltimore & Ohio.

An important conference in Mr. Storrow's office on June 18 was attended by state fuel administrators and representative shippers, called there to discuss what compensation the state administrators should fix for "wholesalers" who handle coal only through barges or steamers which they charter from trip to trip. Application was made by one or two interests to have the charge extend to 5 per cent. of the delivered price, the argument being that the overhead, the capital involved, etc., were so large that 15c. per net ton was entirely inadequate. The subject was thoroughly gone into and all the points of view examined, but clearly the consensus of opinion was that any increase in compensation in view of approaching freight increases would be such an additional burden on the consumer as would not be warranted; that to allow a larger commission would only make it easy for some shippers to divide with "scalpers" nearer the mines; and that the net result would not be more coal for New England but would be merely taking away from the established agencies a certain tonnage that would normally come forward through the regular channels. A feature of the meeting was a clear statement by Thomas F. Farrell, vice president of the Pocahontas Fuel Co., representing the Pocahontas operators. He called attention to the price differential as between the smokeless coals and showed the complications that grew out of it. Mr. Farrell made a further impressive statement with regard to the draft and its effect upon labor supply for the mines.

Later the same day the state administrators gave attention to matters of policy with regard to the new distribution program. It was agreed that in all respects the six New England states should be handled as a unit and the amount of stock that should be supplied preferred requirements and other needs not preferred was discussed in detail.

The movement coastwise has not yet quite recovered from U-boat activity, but a considerable gain was made this week. There has been no day recently when the volume of coal was not largely in excess of the tonnage waiting at the piers. It was only natural that as dumpings decreased last week coal should be diverted to line points and to connecting roads.

Anthracite—Unhappily, there is no increase in the volume of domestic sizes that can be pointed to so far as this territory is concerned. For the first 16 days in June the average daily movement was but 524 cars, still well below the program. The percentage of steam sizes still hovers about 30 per cent.

NEW YORK

The trade urges appointment of state fuel administrator. It sees coal slipping to other markets. Anthracite retail dealers' receipts continue light. Shortage of coal feared by civic organizations. One company advances mine prices of buckwheat and smaller sizes. Bituminous continues short for commercial uses, but bunker coal is in good supply.

Anthracite—The appointment of a state fuel administrator to succeed Albert H. Wiggin, who resigned several weeks ago, would be welcome news to the trade here. Letters have been written to Dr. Garfield urging him to announce Mr. Wiggin's successor, and conferences have been held by representatives of various civic organizations in sections of Greater New York with the local fuel administrator urging such appointment.

Requirements in the Greater City are steadily increasing, and although the allotment made by the anthracite committee of the fuel administration of the entire state represents an increase of 12 per cent., that tonnage could practically be absorbed by local consumers. The trade points out that while the state is without a state fuel administrator to urge its needs this market is not reaping any benefit from the cutting down of Western shipments or of shipments to the 29 counties in western Pennsylvania as ordered by State Fuel Administrator Potter of that state.

The Bronx County Board of Trade is fearful that there will be a decided shortage of coal in that county next winter and has started out to find the reason for delayed shipments. It is claimed that the 21 retail dealers in that county have orders on their books for more than 400,000 tons, while the requirements for the county are placed at 1,344,000 tons.

Although it has been announced that the city authorities have options on 300,000 tons of coal to be sold to the needy next winter, the trade is still in the dark as to where this tonnage is to be obtained.

There has been no change in the situation regarding the sizes larger than and including pea, although some dealers did receive slightly increased shipments over the previous week because of the shortage of boats to carry coal to New England. Some of the largest yards in this city are reported to have contained less than 100 tons of coal at times during the week.

The steam coal situation has gained some strength, and one of the large producing companies has advanced its mine prices for buckwheat, rice and barley 25c. per ton. It has not yet been learned if any of the other companies will do likewise. The demand is spotted, and while some shippers have plenty of barley on hand others have none. Culm is plentiful with some of the shippers.

Current quotations, per gross tons, f. o. b., tidewater, at the lower ports of the follows:

	Circular	Individual		Circular	Individual
Broken	$6.50	$7.25	Pea	$4.90	$5.65
Egg	6.10	6.85	Buck	4.85	5.60
Stove	6.35	7.10	Rice	4.35	4.80
Chestnut	6.45	7.20	Barley	3.85	4.00

Quotations for domestic coals at the upper ports are generally 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice and barley are not fixed by the Government.

Bituminous—The record production as recorded by Government statistics for the week ended June 8, when there was an increase of 1,900,000 tons over the previous week, made practically no change in the local situation. Coal was decidedly short for the spot buyers, while regular customers did not obtain any more than they could conveniently use. There has been no let up in the demand.

Producers and shippers were somewhat surprised by the announcement from Philadelphia on Monday that J. J. Storrow, fuel administrator for New England, had obtained permission from the Fuel Administration at Washington to ship to New England 900 cars of bituminous daily from the central Pennsylvania coal fields. Meanwhile it was pointed out that industries engaged in war production along the Atlantic seaboard are clamoring for coal. If this order is allowed to remain in force it will no doubt result in the New York market losing a portion of its already too meager supply.

Public utilities and their customers are again being urged to exercise the utmost caution in using electricity for advertising purposes and other display illumination. Should this alleged waste continue the suspension of the so-called "lightless night" order may be recalled.

PHILADELPHIA

Anthracite deliveries short. Retail labor troubles serious. New allotment not yet fixed. Production good, as well as car supply, with New England still preferred. Non-war plants denied buckwheat exemption. No coal in company storage yards. Steam prices advanced 25c. Government may act. Culm demand grows. Bituminous trade upset. Heavy rail shipments due to submarines. Car supply sharply cut in favor of southern shippers.

Anthracite—From the point of receipts the local situation continues unsatisfactory. The yards are bare, as coal is delivered as promptly as received. Despite real summer

weather consumers do not let up in their efforts to have deliveries made. As a consequence the dealers increase their pressure on the shipping agencies. During the past week the number of dealers calling on the sales agents has increased. That the dealers are losing no opportunity to get every ton of coal possible is shown by the number who in looking up their records have come across single cars of coal which they purchased in the 1916 period and are coming in to be assured that they will receive this car of coal.

The labor question is becoming more acute with the retailers each day, and they find it extremely difficult to keep enough men on hand to deliver what coal is received.

There has not as yet been any decision as to what part of the 18 per cent. increase of anthracite allotted to this state will be received by local dealers. It is understood that the decision in this matter hinges on the matter of how much coal the various operators have been shipping into the various territories which have now been prohibited from using anthracite.

From the production standpoint it can be said that the tonnage is almost up to the record of last year. The reason that it is not more is only because the men are not in the region, and while the reduction of labor from month to month is not heavy, yet in the aggregate it is bound to make itself felt. Unlike the bituminous region, however, there is hardly any trouble with the car supply, as during the past year or more there have been only a few occasions when any operation was idle for the lack of cars. Following out the request of the fuel administration all operations are now making daily reports of the car supply, and the authorities intend to keep the closest watch possible on this phase of the situation.

Practically all the local manufacturing plants have now had replies from Washington in reference to their applications for exemptions for the use of buckwheat coal. Of course, those concerns on war work found this application to be merely a matter of form. However, those engaged on non-war lines are finding themselves in trouble. Their use of the No. 1 buckwheat has been denied, and they are advised to go on either No. 2 or No. 3 buckwheat coal. Even this does not let them out of their difficulties, for most of them find themselves unable to procure any No. 2 or No. 3 buckwheat, as even these grades are closely sold. As a consequence of these refusals of exemptions a few of the smaller operators have had a few cars of buckwheat coal for sale, which generally have been sold around $4.50 for single cars. In this connection retailers who are selling anthracite for steam use are being closely pressed by the authorities to be careful that all such sales are covered by the exemptions necessary. With the big companies it is at times possible to get small quantities of barley or No. 3 buckwheat, as at times their production of this size is a little in excess of their current needs; but even they are not willing to take on new customers for any definite periods.

It is also well to note in connection with the general anthracite situation that the storage yards of the big companies, which in ordinary years begin about this time to fill up with all sizes of coal, from the domestic to the steam grades, are completely bare and do not hold a pound of coal. There is little likelihood, too, that they will receive any coal, except for a light tonnage of barley as midsummer approaches.

The trade was somewhat surprised when on the 12th inst. the Philadelphia & Reading Coal and Iron Co., from its general offices here, announced an increase of 25c. per ton on all steam sizes from buckwheat No. 1 down. There was nothing to indicate that such a plan was in contemplation, and the increase means quite an item to manufacturers, as in addition to this on the 25th inst. the new freight rates with advances approximating 25 per cent. go into effect. The big companies have little of their steam sizes under contract and this means that they will get the new price on fully 75 per cent. of their production. A feature of the present increase is that the price of Lykens Valley No. 1 buckwheat is higher than the same grade of pea coal, and this has caused quite a little comment. It would not surprise any one to see this price adjusted, for some months back individual shippers were selling their buckwheat to steam users at a higher price than they were getting for their pea coal. The Fuel Administration in this instance simply called their attention to the inconsistency, without requesting any action; but that was sufficient, and the prices were adjusted to a more equitable basis. It is possible that the Government might take the opportunity now that the question is opened to set the prices for steam grades the same as they have for domestic fuel and also for bituminous coal.

While the market locally is not active on culm, it is known that heavy shipments of this material are being made to eastern points. In New England the demand for this coal is increasing and heavy tonnages are going there. While heretofore the independent operators have had the bulk of this trade, having practically blazed the way for it, the larger companies have now gone into the market and are selling a fair tonnage. Most of their trade as yet is through middle houses, who have developed a market for it and called on the big companies for supplies.

The prices per gross ton f.o.b. cars at mines for line shipment and f.o.b. Port Richmond for tide are as follows:

	Line	Tide		Line	Tide
Broken	$4.90	$6.25	Buckwheat	$3.40	$4.40
Egg	4.50	5.85	Rice	2.90	3.80
Stove	4.75	6.10	Boiler	2.70	3.70
Nut	4.85	6.20	Barley	2.40	3.30
Pea	3.45	4.70	Culm	1.25	2.15

Bituminous—Late in the week the bituminous operators received quite a jolt. Due to the good car supply which they suddenly began to enjoy a few weeks since, they were feeling comparatively comfortable as to the immediate future. Then came a drastic ruling that on account of the submarine activity off the coast a greater tonnage of coal must go via all-rail from southern points into New England. This order of the fuel administration simply laid on their backs the central Pennsylvania operators, who had begun to ship heavy tonnages into this market. While recognizing the fact that New England is entitled to a fair proportion of coal, they cannot see why the entire market should suffer so drastically. Prior to this latest edict, on the 14th inst., the tonnages of soft coal coming into this market were quite sizable and consumers were storing for future use. The changed conditions in the car supply up to the 14th inst. were particularly noticeable among the jobbing houses, who after just about existing for months past were again receiving a fair volume of coal, with every prospect of doing some good business for the rest of the year. Even at that no one is without hope that the situation may change as quickly as the unfortunate circumstances arose which made the new ruling on cars necessary.

BALTIMORE

Application of the Maryland compulsory work law comes to aid of coal business. Soft coal supplies fairly liberal, but poor as to grade. Anthracite situation still troublesome.

Bituminous—The iron hand of the law is being extended by the Compulsory Work Bureau of the State of Maryland, of which George A. Mahone is director. In Baltimore the coal yards have been placarded with signs which tell all workers, of whatever degree, that the law of Maryland requires every man between the ages of 18 and 50 inclusive to be continuously employed. Notice is given that three or four days does not constitute a week's work, and prosecution followed by fines and imprisonment, or both, will be inflicted on work slackers. The distribution of coal in the city will be greatly aided by the move. There is now a plan being worked out which will probably extend the same law over every branch of the coal business in Maryland, and mine work should be greatly speeded thereby. Meanwhile the diversion of coal to this city continues comparatively heavy, and there is not much talk now that this or that industry is near the danger line as to supply. There has been some kicking by customers, however, as to the grade of some of this coal. As a matter of fact some of the coal coming here is very poor, and there have been continued heavy rejections by the fuel administrator at the tidewater pool.

Anthracite—The hard-coal situation, with receipts still comparatively light at a time when the big inrush should be taking place, still troubles the retailers and the local fuel administration. Little satisfaction has been gained by either as to the source from which Baltimore is finally to get its coal, if at all, in the proportion needed. The general statement is made that a plan is still being evolved to eliminate long and cross-hauls, and the coal will come through finally—when, no one can say. Meanwhile the trade, despite the protest sent from here to Washington against a freight rate increase before Sept. 1, is prepared to see the raise go into effect before the end of the month. Just how the increase will be apportioned is a matter worrying the trade, but the dealers cannot see how their profit margin can be reduced any in view of the steadily mounting costs of materials and general overhead charges. Receipts here the past week were light, with the exception of pea coal, which is coming through freely.

Lake Markets

PITTSBURGH

Production somewhat improved. Moderate amount of stocking. Car shortage chief limiting factor. Occasional slight price shading.

Production in the Pittsburgh district has been improving slightly, along with the rest of the country. The excellent report made public at the beginning of this week, showing for the whole country 12,465,000 tons of bituminous coal mined in the week ended June 8, is believed to have been helped by the Pittsburgh district as much as by other districts, and production was fully as large last week. Curtailment in this district is still due almost wholly to car shortage, according to operators' reports, little loss of production being ascribed to labor shortage; whereas there is the curious contrast that in the Connellsville region car shortage is about past, and labor shortage is the restrictive influence. With a full-car supply in the Pittsburgh coal district, however, a labor shortage might be uncovered.

There is a trifle more stocking of coal, but on the whole not as much as there should be, to insure an absence of trouble next winter. Retail dealers are well supplied and by reason of the propaganda householders are laying in their stocks early in many cases.

On the whole the market is holding up to the set maximum prices, and brokers are occasionally able to secure a commission from the consumer in addition. There are, however, occasional instances of large consumers buying at a trifle under the set maximum, say 10c., particularly for screened coal. This still nets the operator a shade more than mine-run, as there is no difficulty in securing the full price for slack. The general market remains quotable at the set prices: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district, jobbers being permitted to charge 15c. brokerage in addition.

BUFFALO

Bituminous trade dull. Jobbers looking to Pittsburgh for relief, but not getting much. Some stocking up now. Anthracite scarce. Lake shipments good.

Bituminous—The trade continues unsatisfactory to the jobbers, who are wondering when the better showing is to take place. They recall that the authorities who talked to them at the jobbers' national convention were all sure of a better arrangement, so that they could handle the coal that goes out, but they do not see any change for the better yet.

Last week a large number of Buffalo jobbers were in Pittsburgh looking for coal, but it does not appear that much was obtained. The fact is that demand is not what it ought to be from a jobber's point of view. The consumption is good and there are more reports of consumers stocking up, but the coal appears to slip by without coming into the hands of dealers here.

The supply conditions are much the same as before. Canada has a surplus westward and is gaining on the shortage in the St. Lawrence district. New York state is pretty well provided for but New England is short. It is learned that the authorities are working on a plan to carry coal on the canal, which ought to help solve the transportation problem eastward. One difficulty is that the supply of canal boats is small.

The latest rulings of bituminous prices make them as follows for Buffalo: $4.65 for thin-vein Allegheny Valley, all sizes; $4.45 for Pittsburgh lump; $4.20 for Pittsburgh mine-run and $3.95 for slack, all per net ton, f.o.b.

Anthracite—The demand locally much exceeds the supply, which has run down lately to about half the former amount. The claim is that the Government is taking it. A light supply once or twice a week is all that can be depended upon. Dealers are complaining of a note put in the local papers by the county fuel administrator urging people to lay in their coal now, when the present supply is so light that consumers are raising a big din about it.

The amount of anthracite loaded in the lake trade for the week was 109,000 net tons, of which 49,200 tons cleared for Duluth or Superior, consignee's option, 16,900 tons for Milwaukee, 15,800 tons for Sheboygan, 14,900 tons for Chicago and 12,200 tons for Fort William. Freight rates continue easy at 48c. to Duluth and Fort William, 50c. to Sheboygan, 55c. to Milwaukee and 60 to 65c. to Chicago.

DETROIT

Deficiency in receipts of anthracite and bituminous continues. James Couzens is

named chairman Wayne County fuel committee. Lake movement drags.

Bituminous—Jobbers and consumers alike are inclined to regard the present conditions as lending a far from reassuring outlook to the future. The volume of bituminous coal shipments arriving in Detroit shows no material increase. Receipts range around 400 cars a day and below, when current requirements and the necessity for accumulating reserves should be supplied with from 700 to 800 cars daily. Mine-run is constituting the larger proportion of the incoming shipments. Slack, domestic lump and other sizes are not plentiful.

Despite the fact that Edgar B. Whitcomb has disregarded the demand of W. K. Prudden, Michigan fuel administrator, and continues to decline to turn in his resignation as chairman of the Wayne County fuel committee, the state fuel administrator has proceeded to announce the appointment of James Couzens as Mr. Whitcomb's successor. Mr. Couzens is the multi-millionaire police commissioner of Detroit, former vice president of the Ford Motor Co. In earlier life he was a clerk in the coal office of Alexander Y. Malcomson. He was a member of the Wayne County fuel committee, of which Charles A. Dean was the third member. Mr. Prudden has not indicated whether Mr. Dean is to continue on the committee with Mr. Couzens. Meantime petitions have been circulated in Detroit and are to be sent to the Federal Fuel Administrator and Governor Sleeper, of Michigan, asking for the removal of Mr. Prudden as state fuel administrator or the creation of a new district including Detroit and Wayne County, independent of the remainder of the state.

Anthracite—There is no improvement in the matter of anthracite supply. The daily receipts in June have averaged little more than 30 cars a day. Household consumers are vainly striving to get their winter supply. Retailers are unable to fill orders and some of them are declining to book orders.

Lake Trade—Shipments of coal over the lake routes are falling short of the expectations of shippers and vessel owners. During the early part of last week average daily loading of vessels was about 100,000 tons. Toward the end of the week the movement eased off. To supply needs of the Northwest, it is calculated that weekly shipments should amount to about 1,000,000 tons until the coming of cold weather.

COLUMBUS

Labor shortage as well as shortage of cars is cutting production in Ohio mining districts. Demand for all grades continues active in every locality.

The coal trade in Ohio has been rather slow during the week. This was due largely to a reduction in production, which was reported from all of the mining districts of the state. With the demand for steam, domestic and lake tonnage as insistent as ever, the curtailment of output had a serious effect on the trade in general. The tone of the market is generally satisfactory and prospects are for a strong demand during the remainder of the year.

Domestic trade is still one of the strongest features of the market. With the campaign to "buy now" progressing satisfactorily, dealers report a better demand from all sections. In most cases retailers have orders booked ahead for several weeks, and many cannot possibly be filled until August. Surplus stocks have been depleted and all efforts to accumulate stocks have failed. Available trucks and wagons are kept busy making deliveries. The private consumers who have been waiting for Pocahontas and other fancy grades are now satisfied to take Ohio-mined varieties. Retail prices are firm at the levels which have prevailed since the last change at the mines. Pocahontas is quite scarce. Considerable splint from certain fields of West Virginia is on the market. Jackson lump is not selling actively because of the higher Government prices.

The steam trade is active in all directions. Buying for future needs is now the ruling motive among the larger users. Some of the larger consumers have succeeded in laying in a surplus which is to guard against an emergency. The smaller users are trying to follow the example of the larger consumers. Railroads are taking a large tonnage, as their freight movement is increasing. Taking it all in all, the steam business is gaining in volume.

Lake trade is active, although the tonnage going to the Northwest is not so large as the program provides. This is caused mainly by the shortage in cars in the sections producing lake tonnage. The vessel movement is good, and in some instances boats have been compelled to go up the upper lake ports light in order to keep the ore trade moving. New dock prices recently announced are at lower levels than those prevailing earlier in the year. There is no congestion on the upper lake docks as the interior movement is brisk.

Production has been decreased in practically every section of the Buckeye State. This is especially true of eastern Ohio, Pomeroy and the Hocking Valley. It is estimated that the output in eastern Ohio is about 60 per cent. of normal and in the Hocking Valley and Pomeroy bend about 75 per cent.

CINCINNATI

Heavy demand from all quarters continues to run ahead of available supplies. The Lake movement is up to a large volume.

So far there is no indication of the slightest change in the volume of demand for coal, and unless the deliveries within the next month or so become so large as to take care of the winter's requirements for many consumers, this demand will apparently continue right into the winter season. The ability of dealers to secure and deliver coal to take care of orders on their books is of course limited by their receipts, and these have not been of such proportions as to speed up the storage demand very much. However, as far as domestic consumers are concerned, it is worth remembering that already there has been more coal placed in bins for next winter's consumption than is usually the case by September, and that this will be an important factor in next winter's demand from this class of consumers. It is the large industrial consumers that worry the trade most, as it is virtually impossible for them to store enough coal to make more than a slight reserve against their daily requirements. The business of getting much of the domestic demand out of the way will help materially in handling this problem next winter, however. The Lake movement through Cincinnati is now of considerable proportions, as it normally is during the entire summer season, and the usual large volume of coal from fields supplying this market is therefore going to the Lake ports.

LOUISVILLE

Domestic demand keen, with result that deliveries are so heavy that little surplus stock is being laid up by local yards. Steam demand steady and good. Shortage of eastern Kentucky coal, with improvement of western Kentucky deliveries.

Louisville jobbers and retailers are experiencing considerable trouble in securing eastern Kentucky coal, which is in considerable demand, as such grades are going to the coal byproducts plants and also being shipped to the Southern cotton mills, which are on the exempted list. Some little Hazard coal is coming in, but little of the more preferred Harlan, while Blue Gem is hardly known on the local market.

The situation in western Kentucky has eased up somewhat in the past ten days or two weeks, and the mines are securing a far better car supply, many foreign cars now coming in under the new regulations of the Railroad Administration. This has enabled the mine operators to hold labor, and as a fact they are now obtaining slightly better forces. The situation in that section is more hopeful, and production has shown an increase.

All western Kentucky coal moving into the Louisville district is being unloaded and delivered rapidly on stocking orders, little stock being accumulated on local yards, and retail yards generally near empty. However, with the stocking orders well in hand the retailers expect to accumulate some yard stocks shortly and be in position to take better care of steam inquiries.

Eastern Kentucky is still suffering from shortage of labor, although there is no kick coming just now on the car supply which is equal to all demands. However, labor is not to be had, and nearly all mines are working with small forces; on the other hand, new development concerns are going in so rapidly that it is a question as to where labor will come from for the greatly increased operations.

Due to the embargo against anthracite moving into Kentucky some 48-hour coke is now coming on the market and is meeting with ready demand. The St. Bernard Mining Co., which has large coke ovens at Earlington, Ky., is shipping coke into Louisville. This concern is also getting along nicely with a new power plant at Earlington, which will supply power to a number of mines.

BIRMINGHAM

Market conditions active. Sharp demand for domestic and steam grades continues. Improvement in production as a whole is slight. Much idleness of mine workers, and shortage of labor holds down production 20 to 25 per cent. below normal.

The scarcity of coal is still the dominant feature in the Alabama field, though much effort is being expended by mine owners to stimulate the output by appealing to the patriotism of the miners and other classes of labor around the operations, which is expected to bear some fruit in the way of a better production. There is no hope entertained of bettering the labor supply, hence the stimulation to greater effort on the part of the present organizations must be attempted as the only measure of relief.

Many industrial plants are suffering for an adequate supply of fuel—particularly brick manufacturers, some of which have large contracts for brick to be used in the construction of Government buildings and industrial plants being erected at the behest of the Federal authorities. Coal men point to the fact that there could be no more vital or important step taken by the Fuel Administration than the appointment of a committee on production. A representative in the field to look after this phase of the industry could be of untold assistance in increasing the production.

The storing of domestic coal is going on at a good rate, though receipts by dealers are not half the tonnage desired. Car-load lots are being ordered in increased numbers, the fuel committee issuing 144 permits during May. Figures compiled by the secretary of the commission show approximately 20,000 tons of domestic coal provided for in May.

It is understood that the fuel administrator is now engaged in compiling figures on cost of production of coal in Alabama with a view to formulating a new schedule of mine prices.

Coke

CONNELLSVILLE

No material change in coke production. Slight increase in byproduct coal production. Shortage in labor performance. Furnaces working fairly well.

Coke production in the region continues to hang around the average of 340,000 to 345,000 tons a week. Only in rare instances is car shortage now reported, but there is much said of labor shortage, particularly in the yards. Production of coal in the region, for shipment to byproduct plants, continues to increase somewhat, but on the whole there is inadequate labor performance. Representatives of the Fuel Administration are investigating matters and hope to induce the men to work more regularly.

The blast furnaces in operation have practically a full supply of coke, but few of them have been able to accumulate any surplus. A furnace here and there is out of blast through not being able to secure a regular supply. The Carnegie Steel Co. blew in an additional stack at the end of last week, now having 56 of its 59 furnaces in operation, a remarkably high proportion. Two are out for relining and one is too small to operate when labor is so scarce.

There has been practically no contracting for coke for the period beginning July 1, except for the renewal of a few furnace coke contracts that run on a monthly adjustment basis. Many foundries have been in the market for contracts, but operators prefer to sell from time to time rather than make contracts. The market remains quotable at the set limits: Furnace, $6; foundry, 72-hour selected, $7; crushed, over 1-in., $7.30, per net ton at ovens. Coke screenings from old dumps are bringing up to $6.50, according to the care exercised in preparation.

The "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended June 8 at 341,020 tons, a decrease of 2000 tons.

Middle Western

GENERAL REVIEW

Labor shortage cuts down production. Car supply better than for months.

The shortage of labor continues to be a serious problem with all coal-producing companies in the Middle Western territory. The loss of men is felt more plainly in sections where the railroads have been able to provide a full car supply. Operators who have been making careful checks report that the miners as a class are not availing themselves of the opportunity to get more coal to the surface. Then, too, since the beginning of the war operators have been asking Government officials either to exempt or put the miners in a deferred class.

Production during the past week reached approximately 80 per cent., which seems to be about the limit, unless more miners are available.

H. K. Mack, formerly commercial agent for the Burlington R. R., Paducah, Ky., has been selected by the railroads entering Williamson and Franklin Counties as central car distributor, with headquarters at Herrin, Ill. It is understood that this central distributing office will have telephone connections with all the various yardmasters, and with all coal mines, thereby permitting the distributing office to know early each day the number of cars to be had for the next day's loading. Mr. Mack will also have full details as to what was done, how many cars left over, etc., at all mines under his jurisdiction. If this newly created office meets with the expectation, the same arrangement will be adopted in other large producing centers.

CHICAGO

Heavy buying continues. Large stocks desired before freight rate advance. June 25.

The fact that there becomes effective June 25 a substantial increase in the present freight rate on coal has caused some buying that might have been delayed to a later date. It is not uncommon, however, to hear sales managers say they have more orders on their books for size coal than they can fill for the next 60 or 90 days, unless they can get more coal out of their mines. This condition does not exist on fine coal, although quite a number report they are comfortably ahead with screening orders.

Quotations in the Chicago market are as follows, per net ton f. o. b. cars at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Springfield	Carterville	Grundy, La Salle, Bureau and Will.
Steam lump	$2.55@2.70	$2.55@2.70	$2.95@3.10	$2.55@2.70	$2.55@2.70	$3.25@3.40
Domestic lump	2.55@2.70	2.55@2.70	2.95@3.10	2.55@2.70	2.55@2.70	3.25@3.40
Egg or furnace	2.55@2.70	2.55@2.70	2.95@3.10	2.55@2.70	2.55@2.70	3.25@3.40
Small egg or nut	2.55@2.70	2.55@2.70	2.95@3.10	2.55@2.70	2.55@2.70	3.25@3.40
Stove	2.55@2.70	2.55@2.70	2.95@3.10	2.55@2.70	2.55@2.70	3.25@3.40
Chestnut	2.55@2.70	2.55@2.70	.....	2.55@2.70	2.55@2.70	3.25@3.40
Pea	2.55@2.70	2.55@2.70	.....	2.55@2.70	2.55@2.70	.....
Washed egg	2.75@2.90	.....	.....	2.75@2.90	2.75@2.90	3.45@3.60
Washed stove	2.75@2.90	.....	.....	2.75@2.90	2.75@2.90	3.45@3.60
Washed nut	2.75@2.90	.....	.....	2.75@2.90	2.75@2.90	3.45@3.60
Mine-run	2.35@2.50	2.35@2.50	2.75@2.90	2.35@2.50	2.35@2.50	3.00@3.15
Screenings	2.05@2.20	2.05@2.20	2.35@2.50	2.05@2.20	2.05@2.20	2.75@2.90
Washed slack	2.05@2.20	.....	.....	2.05@2.20	2.05@2.20	2.75@2.90

MILWAUKEE

Fuel administrator orders anthracite deliveries to begin, leaving prices to be adjusted later. Soft coal schedule fixed. A fair supply of hard coal thus far.

The coal situation at Milwaukee has loosened up to the extent that anthracite is now being delivered from all the docks which handle this grade of coal. Dockmen were holding their stocks until such time as the Government price schedule was announced, but retailers and consumers were so clamorous that State Fuel Administrator Fitzgerald directed that deliveries be made without further delay, leaving the matter of price open to Federal regulation. Because of the temporary check in output there is a goodly accumulation of anthracite to be distributed. From the opening of navigation up to and including June 17, 101,150 tons went over the docks here. In addition, some has come by rail. The sum total is somewhat more than was received last year during the same period.

The schedule of prices for anthracite will be fixed when the cost of handling coal over the docks has been determined. The inquiry as to this is still on. The margin between dock prices and the figures charged the consumer is put at $2.25 per ton with an extra charge of 50c. per ton when fuel is carried in to bins. This includes the retailer's overhead expense and also his loss due to shrinkage. Only six Milwaukee firms receive anthracite, but there is an army of middlemen.

Soft coal is moving out freely. Receipts are falling behind those of last year and it is thought there will be a shortage of steam coal when the season ends. Manufacturers are being urged to economize in every way possible. For the present dealers are allowed to charge as follows for soft coal, delivered: Pittsburgh, Youghiogheny and Hocking—Lump, $6.80; pile run, $6.55; screenings, $6.30. West Virginia Splint—Lump, $7.30; pile run, $7.05; screenings, $6.80. Kanawha Gas—Lump and egg, $8.05; pile run, $7.05; screenings, $6.80. An extra charge of 50c. per ton is made when fuel is carried in.

Coke is selling at $10.75 with the sanction of the fuel administration. This is somewhat higher than usual and presages a stiffening in hard coal prices in order to maintain a proper margin between the two grades of fuel. Thousands of tons of coke are being delivered by the local producers.

Dealers are adhering strictly to the rules laid down by the Federal Fuel Administrator. Users of anthracite are allowed only two-thirds of their normal supply, leaving the other third subject to circumstances later. Manufacturers are being refused anthracite, unless they have special permission, nor can anthracite be furnished to consumers who can use bituminous. Chestnut anthracite is being reserved for consumers having self-feeding magazine stoves. Dealers have orders to report sales at regular intervals.

KANSAS CITY

Plenty of slack going in storage. Dealers accepting orders only for mine-run. Some dealers allowing their stocks to dwindle.

A gratifying volume of slack is going into storage at Kansas City, industrial plant managers going as far as they can in providing against the expected shortage of next winter, and patriotically doing their part in helping the movement this summer. It is said that more than 100 cars of Arkansas semi-anthracite slack has been taken by industrial plants, and much even by office buildings. Many former users of Cherokee and other Kansas slack are storing the semi-anthracite. The latter has a freight rate of $1.60 and mine price of $2.75, against the 90c. freight rate and $2.80 mine price of Cherokee; but the Kansas softer coal will not store. The reduction in price of the Arkansas coal June 1, from $2.85, has had less effect on promoting the movement of Arkansas slack than has the coming advanced freight rate.

The demand for slack from Arkansas is exceedingly strong over a considerable part of the district, and consequently the production can be maintained at a high level. Previously to June, the mines were handicapped by inability to move slack in cars and by lack of equipment and labor to store the slack at the mines. Now that the slack is moving freely, the lump coal is also going rapidly over the district.

ST. LOUIS

An unusual condition, with practically a full car supply on all roads. Transportation improved and all coal easier. Railroad buying still light. Steam market gone to pieces, while domestic demand continues good. Country business improved. Labor shortage greatest handicap.

The St. Louis market enjoys at the present time practically a full car supply on all roads. Transportation has improved, and there is a better movement of loads and empties. In the Carterville field the mines are working steadily, but the labor shortage continues and the tonnages fall slightly week after week at most mines. There has been, during the past week, a heavier tonnage of this coal moving into the St. Louis market than for many weeks previous, but not near as much as the market could absorb. The railroads seem to be buying heavily in this field in preference to other fields. The same conditions prevail in the Duquoin district.

The Mt. Olive mines are working steadily, producing just about enough coal to take care of the demand, with an exceptionally good car supply and with less labor difficulty than in any other field. Throughout all the fields there has been an exceptionally hard time moving steam sizes of coal, and some mines have been idle on account of their inability to move screenings.

In the Standard field the conditions are unusually bad. There is an overproduction, and several mines are having a hard time working on account of the surplus of steam coal. The railroads are not buying the tonnage in this field that they were a year ago, or that they should be buying now. The car supply is full and transportation is much improved, but there is going to be a labor shortage here that is going to grow worse than in other fields, for the reason that the mines are not working steadily and the miners are going to other places where they can secure steady work.

Standard screenings got down to $1.25 and 2-in. lump to $2.15 during the past week, and many mines had a surplus tonnage left over with no place to ship it. In the face of these conditions the brick plants have been shut down because they have used the coal allotted to them for the present year. There is an unusual demand for brick, and there is an over-supply of coal.

The demand for coal from the country is fairly good. Especially now, in view of the fact that on the 25th freight rates increase 25 per cent.

The prevailing circular at St. Louis is, per net ton f.o.b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.90	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.90	2.55@2.70	2.35@2.55
2x3-in. nut	2.55@2.90	2.55@2.70	2.35@2.55

Ocean Shipping

OCEAN FREIGHTS

W. W. Battie & Co.'s Coal Trade Freight Report

June 17—The steamers available for Cuban and West Indian coal orders have decreased materially, a few having been sunk by submarines and a large number diverted to other trades, this causing an actual shortage, particularly of prompt boats. The Chartering Committee has named rates for Bermuda and Curacao, as noted below. To other destinations, little business is being completed, owing to the tonnage scarcity. Rates are as follows:

STEAM

	Tons Discharge
Havana, $6	1,000
West Indies, $7.50	600
Cardenas or Sagua, $9	300
Cienfuegos, $9	500
Port of Spain, Trinidad, $11	500
St. Lucia, $11	500
St. Thomas, $10	500
Barbados, $11	500
Kingston, $9.50 and p.c.	400
Santiago, $8.50	500
Santiago, 9.00	400
Guantanamo, $8.50	500
Guantanamo, 9.00	400
Bermuda, $9.50 and p.c., and discharged free	300

SAIL

Rio	$19.50 net	Montevideo	$19.50 net
Santos	19.50 net	Pernambuco	18.50 net
Buenos Aires	18.50 net	Bahia	18.50 net
La Plata	18.50 net	Para	15.50 net

Gross rates $1.50 per ton in excess of net rates.

On all above rates charterers pay vessels' towage to coal port.

To nitrate range about $16.50 gross prepaid.

The Chartering Committee's rate by steam is $18 net to the Plate and $19 net to Rio or Santos, but at the moment there are no steamers offered for this business.

General Statistics

BALTIMORE & OHIO

The following is statement of coal and coke tonnage moved over the Baltimore & Ohio system and affiliated lines during the month of March, 1918, as compared with the corresponding month of the previous year:

	1918 Tons	1917 Tons
Coal	3,644,103	2,999,163
Coke	272,725	318,194
Total	3,916,828	3,308,357

COAL AGE

Volume 13 NEW YORK, JUNE 29, 1918 Number 26

Without Women or Culm Piles

By R. Dawson Hall

OF ALL the national problems in Great Britain during the war, none has been more difficult than that of recruiting the labor forces of the war industries. The problem would never have been solved with any degree of success had women not been available to do much of the work.

It may safely be said that there is less danger in depleting the forces of our machine shops and the clerical and road-maintenance forces on our railroads than in reducing the forces in our mines. Women can run the lighter kinds of machines. They can operate, and have for years operated, telephones and telegraphs as successfully as men. They can handle express and even light freight and are doing so extensively in Great Britain and France. Already they are tamping ties in some states of this Union. But they cannot by any possibility, without a grievous shock to all our innate impulses, work in the mines. By stringent laws they are excluded even from working around such places.

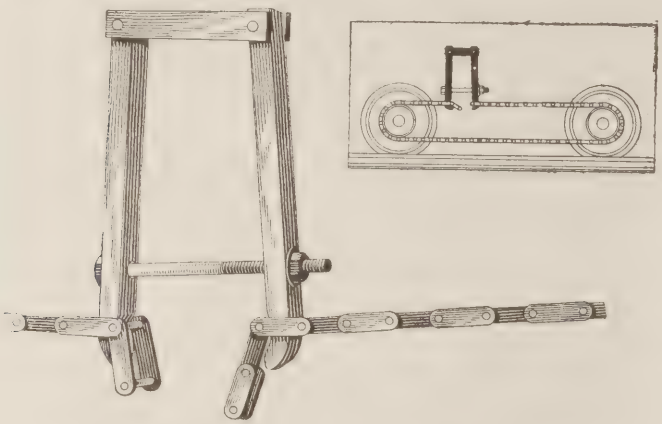
Hence many lines of machine and railroad work and, be it added, farm work can be supplied with labor as soon as the labor forces are depleted, but mine work cannot be so supplied. For this reason, if for no other, mine labor, and especially anthracite mine labor, should be zealously guarded. The supply should never be allowed to dwindle. The draft should not for an instant be allowed to curtail the power of production of the industry.

Once crippled, it is hurt beyond recovery. There is no substitute labor force available. Only young men would have spirit enough to try the hazards of this new trade, and all such men have been drained away by the war. To older men living in cities or farming districts, the mines seem vested with a horror all their own. Thus the enterprising males are gone, and the women who are willing to undertake any kind of honest labor for the national advantage or for a generous wage are unavailable, because the industry is not permitted to accept their services.

It looks, therefore, as if accretions to the mining forces are unlikely. For this reason it is necessary to guard against depletions, certainly against further reduction in the working force. When the war broke out in Europe the anthracite region was quite short of men. New men ceased to come in. Many went to Europe to fight, and others went to the munition factories. The enlistment of men was followed by the draft, and now there is only 82 per cent. of the former scant force.

Up to the present time, the culm piles have made up the deficit. But this easy source of supply, afforded us by the labor of past generations, is fast being used up. Be it noted that the unsightly, but useful, culm banks hid the true situation from the public. We may yet for that reason regret that they ever existed. They have innocently disguised from a not too well instructed people the fact that the mine workers were being spirited away in numbers and were thus leaving flat on their back all the industries dependent on the coal that those mine workers were wont to produce.

Let us wake up to the situation and deduct the culm-pile product from the total and thus determine where the industry will be. Present coal production is not sufficient to meet requirements; it will be still less when the washeries have prepared the last pound of culm. Is it wise, therefore, to draft or enlist any more anthracite miners in the national forces? Anthracite production is slim to famine now; it will unquestionably be slimmer yet if remedial measures are not taken.



IDEAS AND SUGGESTIONS

Traction Chain Splicer

BY FRED W. SAKON
Johnstown, Penn.

On ordinary mining machines the propelling chains after they have been used for some time develop a certain amount of slack. If this is not taken up it will cause trouble through the chain slipping over the sprocket teeth. In other words, the chain slips a tooth.

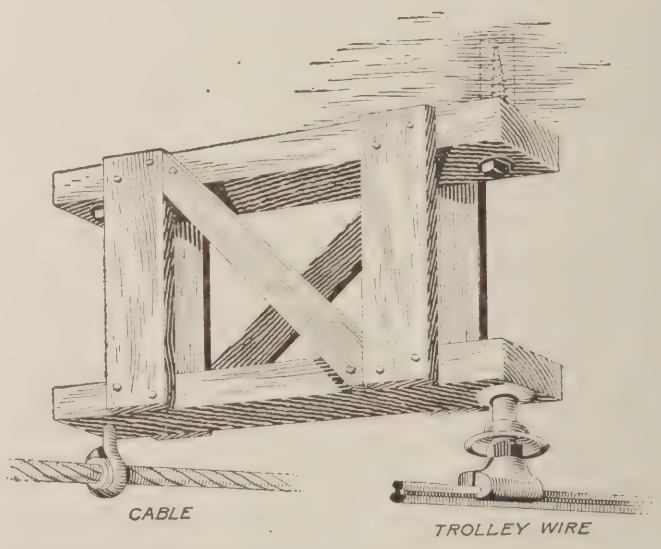
A simple device for taking up slack and pulling the chain together in case it is broken can be made by a

SIMPLE DEVICE FOR TAKING UP SLACK

blacksmith in a short time. This requires two pieces of steel 1½ in. square by 12 in. long. One end is forged to pass through the chain and is notched to fit the bushing so as to prevent slipping out when pulling. Drill a $\frac{11}{16}$-in. hole in the opposite end of both pieces, also in each end of two pieces of $\frac{3}{8}$ x 1½ x 5-in. strap iron. These straps are bolted at the top end of the main hooked bars so as to form a hinge joint. Another $\frac{11}{16}$-in. hole is drilled about two-thirds of the way from the hinge to the hook. This is to take a ½-in. bolt 9 in. long threaded 6 in. of its length, which acts as a drawbolt.

To use this device simply insert the chain puller in the chain and tighten up the nut. This draws the chain tight and a link may be removed or the chain spliced. The device eliminates the tiresome job of trying to pull the chain together by hand or with bars that may slip and possibly injure the man doing the work.

Combined Feed Cable and Trolley Wire Hanger



BY R. W. MAYER
Connellsville, Penn.

The United States Coal and Coke Co., of Gary, W. Va., uses one hanger to support both the trolley wire and the feed cable which supplies it with current. Two pieces of hard wood, about 3 ft. long, 3 in. thick and 6 in. wide, are used in making the hanger. One of these is fastened to the roof crosswise of the entry, by means of four lag screws. Two are sufficient when the load is not heavy.

Holes 1½ in. in diameter are drilled into the roof to a depth of 8 in. and wooden plugs driven tightly into them. The ends of these plugs are then cut off even with the roof. The holes for the successive hangers are kept in line by sights or by plumbing up from the rail.

By means of a templet the holes in the roof for each individual hanger are drilled the correct distance apart for the lag screws. Then, through the holes in the timber placed against the roof, the lag screws are driven into the wooden plugs already referred to. Lag screws ½ in. in diameter and 10 in. long are used. These hold the timber rigidly in position, the latter forming the support upon which the balance of the hanger is built. All the lag-screw holes and bolt holes are bored through the timber outside the mine. Templets are employed to get the holes in the correct position.

A second piece, the same dimensions as the roof timber, is supported by means of 1 x 6-in. lumber. Four of these pieces are used as upright supports, two being fastened on each side of the timbers about 8 in. from their ends. Each pair of uprights is placed on directly opposite sides of the timbers. The upper or top end of the upright is fastened to the roof timber and the lower or bottom end supports the lower timber by being

HANGER SUPPORTS BOTH TROLLEY WIRE AND FEED CABLE

fastened to its side. The height of the lower timber is maintained a uniform distance above the top of the rail throughout the entry. This is accomplished by varying the length of the 1 x 6-in. pieces. The trolley and feed wire are fastened to the lower cross-timber.

Cross-braces of 1 x 6-in. lumber are fastened X-wise between the uprights and connect the two cross-timbers. One piece fastened to the edge of both cross-timbers

on each side is usually sufficient. The ends of these braces are cut beveled, so that they will rest against the edges of the upright supports.

The ends of the hangers are placed as close to the rib of the entry as practicable. The trolley wire is fastened to the wooden crosspiece by the usual insulated metal hangers. The feed cable is supported by a metal hanger fastened to the lower timber near the end next the rib.

To Speed Up Development Work

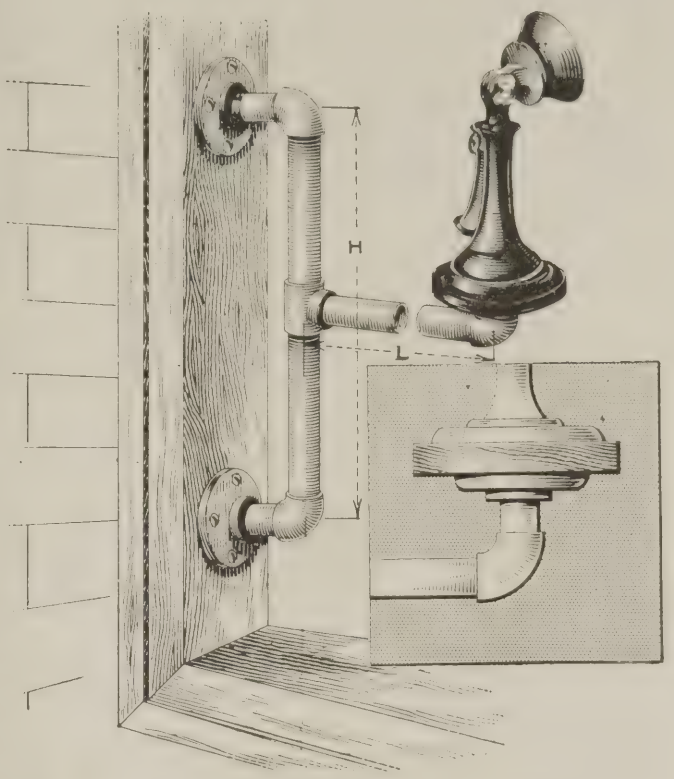
By Harry Goodman
Duquoin, Illinois

In order to obtain the full benefits under the now commonly used panel system it is necessary to work out quickly the panel when once it is started. That this may be done, as much entry driving or development work as possible must be completed so that the panel entry will be driven to its boundary before commencing on the room.

Thus when all these rooms start to work together so much coal comes from this limited area that it pays to keep a motor parting or branch on the main entries between each (or every second) pair of panels. This means grading and laying a motor road. which necessitates a simple system of keeping such work up close to the face without stopping the entries during construction.

To begin with, the location of such partings should be determined in advance so that the main entry can be widened out to hold the parting while it is being driven. Secondly, where it is customary to keep the track only in the haulage entry, except for a turn through every second or third cross-cut to get the coal out from the back entry, exactly the opposite should be done so that the track will be kept up in the back entry from the end of the motor road. As soon as the main entry is up to where new panels are to be turned off construction work may be started in the now vacant haulage entry. This work can be completed easily, before the main entry has again advanced to another parting, and an hour's work will suffice to cut in the temporary track, over which the entry coal has come uninterruptedly, to the main line.

As there can be only six places (the main and right and left panel entries) ahead of such work the slight disarrangement of air should not be dangerous except in an extremely gassy mine. Anyhow, the great advantage is secured of doing the track and wiring when convenient while the development work continues all the time.



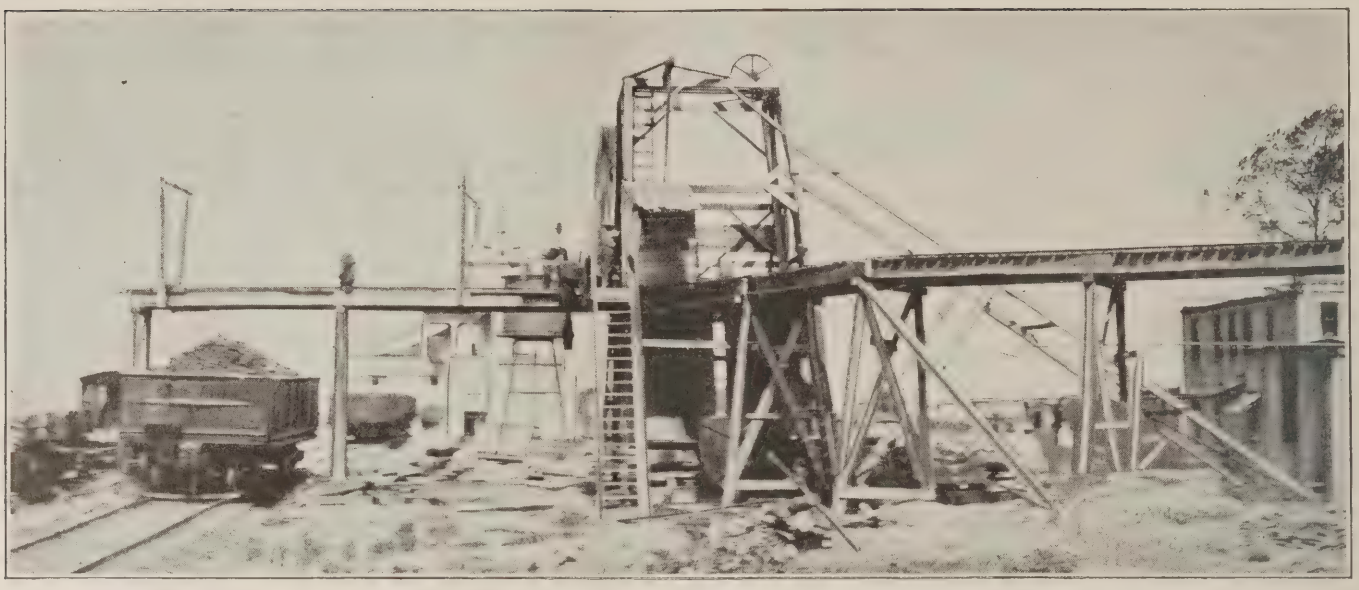
Light for the Drafting Room

It often occurs that a room not originally intended for drafting purposes is used as such and it is also frequently situated on the wrong side of a building, causing annoyance and inconvenience on account of the direct rays of the afternoon sun falling upon the drafting table. This condition may be eliminated, without sacrificing any of the light, by tacking or pasting a single thickness of tracing paper over the offending window. The paper diffuses the light without detracting from its usefulness, and is easily and quickly applied.—*Engineering and Mining Journal.*

Swinging Telephone Bracket Made From Pipe Fittings

By A. L. Renard

In a certain power plant the engineer's office was a small room in one corner of the building. A window in this office opened into the engine room. The engineer's telephone normally reposed on his desk in the office. But when he was in the engine room and a



FIGS. 1 AND 2. SWINGING BRACKET AND DETAILS OF ARRANGEMENT

call came, it was his practice to reach through the window and pick up the desk set so that he could use it without having to go around through the door into the office.

The dangling telephone cord gave some trouble by catching on ink bottles and on papers, and finally became a real nuisance. Fig. 1 shows how the difficulty was eliminated by the application of a swinging bracket, which was, in odd times, made up of old pipe fittings, which were picked up around the plant. Fig. 2 indicates the details of the arrangement.

This drawing is almost self-explanatory. The distance *H* should, for satisfactory operation, be about 3 ft. The length of the arm *L* will vary according to conditions. For the bracket which is being described, this length *L* was such that when the telephone was swung into the office it assumed a position directly over the center of the flat-top desk. The base of the telephone was held to the $\frac{3}{4}$-in. wooden disk with straps of $\frac{1}{16}$ x $\frac{1}{2}$-in. sheet brass which are not shown in the illustration. The cord of the telephone was carried through a leather loop on the window frame in such a way that it swung with the arm and did not catch on things when the arm was moved. The idea may be adapted for use in many other instances.

TEMPORARY SINKING HEADFRAME AND TRESTLES AT SITE OF PROSPECTIVE MAIN KATHLEEN TIPPLE

Kathleen Mine of the Union Colliery Company at Dowell, Illinois

ON A tract of over 3000 acres about 5 miles south of Duquoin, Ill., development is well under way for a big 1000-ton-per-hour coal plant. There is no bigger operation contemplated or under construction in the state. Eugene McAuliffe, of St. Louis, Mo., is the president and general manager of the Union Colliery Co., the owner and operator of this new plant—the Kathleen mine.

The improvements already made give abundant evidence of the character of the new operation. Substantial up-to-date buildings are equipped with the most modern devices for handling coal efficiently and economically. Possibly the most striking object at the mine today is the reinforced-concrete tipple at the air shaft, the only structure of its kind in the Illinois-Indiana field. The main tipple will be of structural steel and will occupy the site of the temporary sinking outfit, which is south of the concrete tipple. Both air and hoisting shafts are through the coal, and the two shafts were connected up on June 8, 1918. Coal is now being hoisted to the surface through both shafts and loaded on railroad cars for shipment.

The concrete tipple was built to handle coal until the steel tipple could be constructed. Steel in large quantity for quick delivery is practically out of the question for most industrial requirements. In view of this the Union Colliery Co. used cement in the structure in question. This tipple will be available at any time later to handle 2000 tons of coal per day if need be, in the event of a temporary failure of hoist motors at the main shaft or stoppage of operations at the large tipple from any cause. The main shaft tipple is equipped with a one-car rotary dump and screens for making several sizes of coal. The mine cars have solid ends, roller bearings and a capacity of five tons.

In the face of most trying circumstances and during a winter of most unusual severity, work was prosecuted and the tipple built. Concrete was run with the thermometer at 24 deg. below zero without freezing. This was accomplished by housing-in the tipple with lumber and brattice cloth and using salamanders to keep up the inside temperature. In addition the water used in the concrete was heated (as were also the other component materials) by means of steam coils.

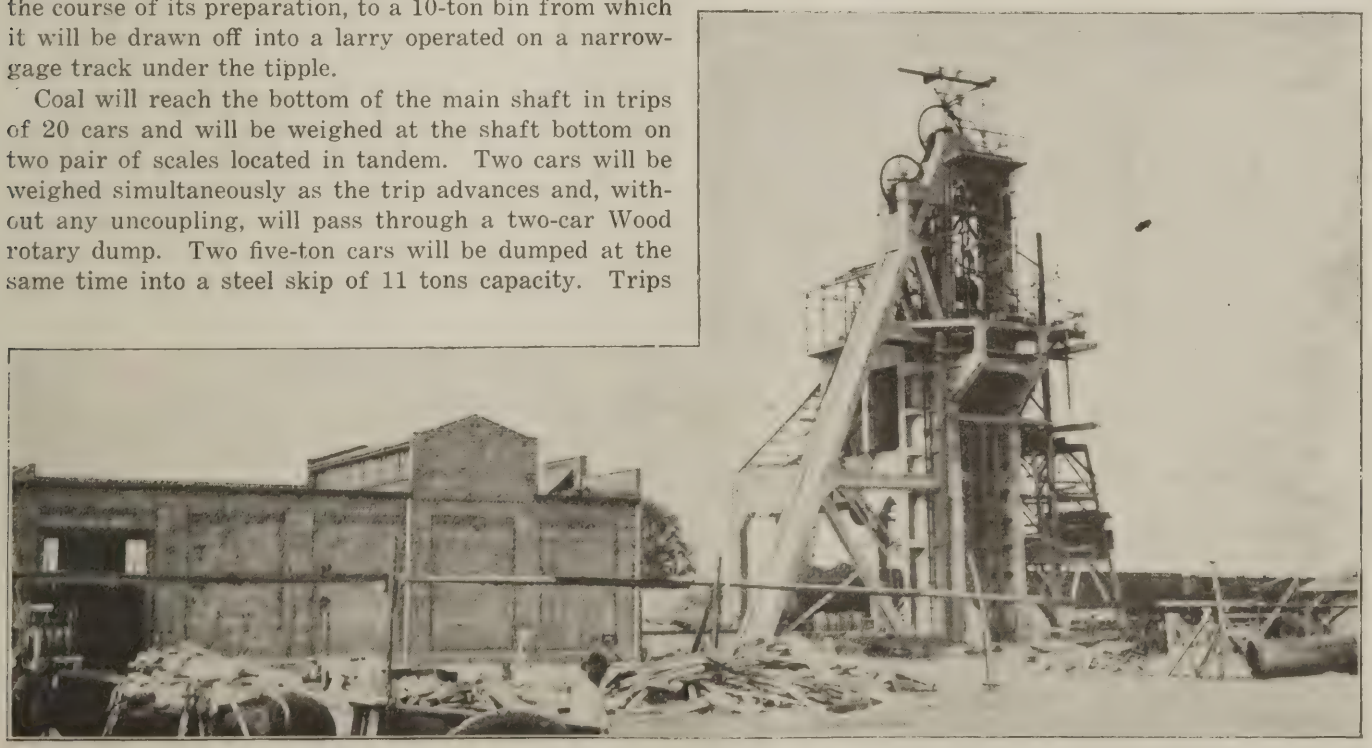
Men and materials will be hoisted through the shaft at the concrete tipple. This shaft also will be used for ventilation. It will be equipped with one double-deck cage for handling coal and materials on the lower deck, or 50 men on the combined decks at one time. This cage is counterbalanced with a steel frame filled with a concrete of cement and scrap-iron aggregate. The hoisting equipment consists of a Wellman-Seaver-Morgan outfit, with an 8-ft. cylindrical drum operated by a three-phase, 60-cycle, 2300-volt, alternating-current, 250-hp. motor. The motor is connected to the hoist by a Francke flexible coupling and Fawcus herring-bone gear. This hoist is air-controlled and is provided with overwind and maximum speed-control devices.

In the power end of the room is a 200-kw. motor-generator set transforming 2300 volts alternating current to 250 volts direct current. This electrical outfit is to operate six-ton Goodman locomotives. With the development of the mine the motor-generator sets will be carried below, having one set on either side of the mine. The engine and power house has concrete foundations, vitrified brick walls and steel roof trusses. Near the engine and power house is a 20,000-gal. water tank with concrete foundations and steel supports. This will supply water to the washhouse.

Near the power house is the outdoor substation constructed by the Delta-Star Electrical Co., of Chicago, Ill. The concrete brick building contains the oil switch equipment. The outdoor substation transforms a line voltage of 33,000 alternating current to 2300 volts. The inside substation eventually will contain switch boards and transformers for changing 2300-volt alter-

nating current to 220-volt current. During development 220 volts alternating current will be carried to the bottom through the air shaft on the high-voltage cables. Later 2300-volt current will be carried to the bottom, thence to a transformer located as close as practicable to the machinery, where it will be reduced to 220 volts. An extension of the air-shaft power house will be used as a boiler room and contain two 50-hp. tubular boilers. One boiler is to be maintained for heating water for the miners' washhouse and for heating the office and engine room in winter. The second boiler will be kept as a reserve.

A Jeffrey fan (5 x 12 ft.) is being installed close to the air shaft. The fan will be of steel, of reversible type and be housed in a concrete, vitrified paving brick building. The fan motive power will be a 200-hp. alternating-current motor. An emergency fan drive will consist of an 80-hp. steam engine.



The air shaft is 12 ft. by 26 ft. 4 in. inside dimensions. This shaft is lined to the rock with 2½ ft. reinforced concrete, which serves as a foundation for the tipple. Below the rock the concrete lining is from 6 to 18 in. thick, depending on the strata. Steel H-beam buntons are embedded in the concrete. The air shaft has an air compartment 8 ft. by 8 ft. 6 in. and a hoist compartment 8 ft. by 12 ft. 6 in.; the remaining space contains a stairway and a compartment for the counterweight, electric cables and pipe lines.

The main shaft is 11 ft. by 19 ft. 1½ in. inside dimensions. It is 250 ft. from the surface to the bottom of the coal seam at this shaft. The thickness of concrete lining and its construction is the same as in the air shaft, and the steel buntons are bedded in the concrete the same as in the other shaft. The steel tipple will rest on the heavy concrete lining, extend over four railroad tracks and make the several grades of coal generally made in Illinois. The tipple will be equipped with shaker screens and three picking tables. Conveyors will carry refuse, separated from the coal in the course of its preparation, to a 10-ton bin from which it will be drawn off into a larry operated on a narrow-gage track under the tipple.

Coal will reach the bottom of the main shaft in trips of 20 cars and will be weighed at the shaft bottom on two pair of scales located in tandem. Two cars will be weighed simultaneously as the trip advances and, without any uncoupling, will pass through a two-car Wood rotary dump. Two five-ton cars will be dumped at the same time into a steel skip of 11 tons capacity. Trips after dumping, and without the necessity of recoupling, will be pulled from the empty car tracks to the working places by motors. The labor and delay of coupling and uncoupling cars is thus eliminated. The loaded trip will pass through the dump under the control of three sets of Lepley cagers.

There is under construction, for hoisting at the main shaft, a Wellman-Seaver-Morgan, cylindro-conical drum hoist. The small end of the drum will be 8 ft. and the large end 11 ft. in diameter with a face of 5 ft. 3 in. The diameter of the brake ring will be 10 ft. This hoist is to be operated by a flywheel (Ilgner) set made by the General Electric Co. This electrical hoist is a 600-kw., 500-volt set with a 20,000-lb. flywheel. Underground the main haulage motors will be 18- to 20-ton machines with six-ton Goodman locomotives for gathering. Goodman alternating-current shortwall mining machines with 7-ft. 6-in. cutter bar will be used. The mine track will have 40-lb. rail on the main lines and 20-lb. rail in rooms. It is also interesting to note that steel ties will be used on mine tracks. The No. 6 seam averages 8 ft. 3 in. in thickness at this mine, and 1 ft. to 1½ ft. of top coal will be left up to protect the top in entries and rooms to be recovered on retreating. The mine will be developed on the panel system, and where conditions are favorable the pillars will be recovered.

The track construction at this new plant is somewhat unique for this flat country. The track is 5 ft. above the flood line in the creek bottom. As the expense of a gravity grade was considered prohibitive, the track was planned without a grade with the exception of 800 ft. of track extending from above the air shaft to 100 ft. below the track scales. Cars will be moved by gravity on this grade. Empty and loaded cars in yards above and below the tipple will be moved by a narrow-gage steam locomotive operating between storage tracks. A suitable device on the locomotive engages

KATHLEEN CONCRETE TIPPLE WITH HOIST AND BOILER HOUSE ON THE LEFT

SOUTHWEST VIEW OF KATHLEEN CONCRETE TIPPLE

the end sills of cars, moving ten empties at a time to a point where they are handled by gravity. Subsequently the loaded cars are moved back five at a time, thus making car control independent of load, bad brakes, freezing weather and other adverse conditions.

A shop and store room 40 x 120 ft. at the first story has been constructed of concrete vitrified paving brick and steel roof trusses. The shop is covered with a tile roof and is equipped with a 30-hp., alternating-current motor operating a power hammer, lathe, drill press, planer, iron and wood saws, blowers, emery wheel, etc. At one end of this building is a second story with 40 x 40-ft. floor space, containing mine offices with separate fireproof vaults for engineer's and office records. Below one end of this second story and next to the supply room are the offices of the storekeeper and time clerks.

Two 150-ton railroad track scales—50 ft. long, of concrete and steel—to weigh coal are installed; these scales are on parallel tracks below the tipples. The Central Illinois Service Co. will furnish power, having built a 33,000-volt line from Royalton. A town site of 360 acres has been purchased and laid out in building lots. Part of this tract is covered with a fine growth of timber, six acres of which are to be improved for park purposes and provided with recreation equipment for the children. This new town is to be called "Dowell" and has under construction at present a hotel, brick store building and 25 houses.

The public utilities connected with this company will furnish a market for the entire output of the mine. The main office of the concern is at St. Louis, Mo., with branch offices at Milwaukee, Racine and Kenosha, Wis., and Detroit, Mich. This company also owns the Western Kentucky Coal Co., which operates nine mines in western Kentucky, with the largest fleet (300 barges) of barges on the Ohio and Mississippi Rivers. It is about the only river company left. The local officials of this company at the Kathleen mine are Edward Bottomly, general superintendent; Charles Gottschalk, chief engineer; Robert England, top foreman, and James Wilson, mine manager.

Test on a Jeffrey Fan

By W. D. Owens
West Pittston, Penn.

The Lehigh Valley Coal Co. recently erected a ventilating fan of the Jeffrey type at its No. 10 tunnel, Campbells Ledge Mines, on which I had the privilege of making a test on July 1, 1917. I found conditions as follows: Diameter of fan, 7 ft. 11 in.; width of fan, 4 ft. 1½ in.; including the rims to which the blades are attached at the outer end and also the center plate.

The test was made in vacuum; that is, the mine was walled off so that no air could enter the fan. The fan then ran at 136⅔ r.p.m. The theoretical depression produced by such peripheral speed per minute, according to Daniel Murgue's theory, equals $\frac{V^2}{G}$ found as follows: The peripheral speed was $\frac{7 \text{ ft. } 11 \text{ in.} \times 3.1416 \times 136.66}{60} = 56.64_3$ ft. per sec. The barometer reading during the test was 29.60 in., and temperature equaled 76 deg. The weight of the air per cubic foot was consequently $\frac{1.3253 \times 29.60}{460 + 76} = 0.07318$ lb. Hence $\frac{56.643^2 \times 0.07318}{32.16 \times 5.2}$ 1.40 in. of theoretical pressure or water gage.

Two water gages were used, and each agreed with the other, both showing 1.18 in. of pressure. The fan thus developed an actual pressure equal to $\frac{1.18}{1.40} = 84$ per cent. of its theoretical capacity. This is the best

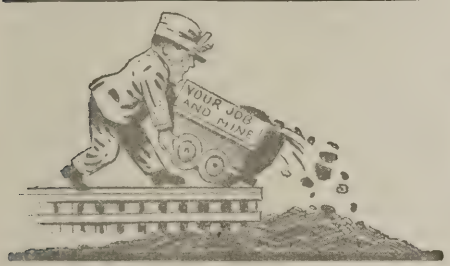
result I have ever obtained from many experiments. The fan was then tested while ventilating the mine. It then ran at 132 r.p.m. and produced a mine depression or water gage of just 1 in. The theoretical depression at this speed is found as follows:

$$\frac{132 \times 3.1416 \times 7.916}{60} = 54.71\ ft.$$

and

$$\frac{54.71^2 \times 0.07318}{32.16 \times 5.2} = 1.309\ in.$$

Therefore the fan produced a water gage of $\frac{1}{1.309} = 76$ per cent. of the theoretical depression. This was a splendid result, particularly so considering the great volume of air the fan produced. Several tests showed this quantity to be not less than 110,000 cu.ft. per minute.



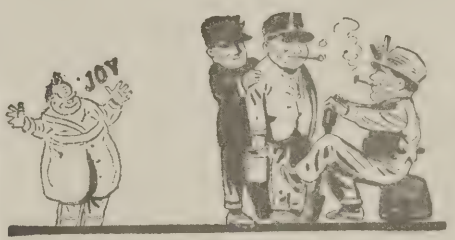
The fan is driven by electric power, and during the test when the fan was running in vacuum it required 8 hp. to operate it; but when ventilating the mines, running at 132 r.p.m., it consumed 33 hp. Now the horsepower in the air circulated was as follows:

$$\frac{110{,}000 \times 5.2}{33{,}000} = 17.3\ hp.$$

And this proves, as might be expected, that there is no definite relation between the horsepower circulating the air through the mines and the horsepower required to operate the fan. It is true that the horsepower developed in the air by a fan of the Guibal type is relatively nearer to the engine power, simply because of the inability of this type of fan to produce a large volume of air and at the same time to produce a high percentage of mine depression compared with the theoretical depression. The Guibal types of fans in general are only able to produce their own cubical contents, even when operating in the open atmosphere, and much less when applied to actual ventilating of the mines. But the Jeffrey fan, as shown by this test, produces considerably more.

The total width of this fan was given heretofore as 4 ft. 1½ in. This dimension includes the circular rim on each side of the fan to which the blades are fastened, also a plate in the center of the fan. This leaves the actual unobstructed width of the fan, which forces the air out, as 3.56 ft. The diameter of the fan as previously stated is 7 ft. 11 in.; therefore, the cubical contents of the fan space is 175.9196 cu.ft., and this multiplied by 132 revolutions equals 23,221.389 cu.ft. The quantity of air produced by this fan was previously stated as being 110,000 cu.ft.; therefore, the fan produced 4.73 times its own cubical contents; and even if the "rims" and center "plate" are calculated into the volume of this fan, taking the width as 4 ft. 1½ in. its volume would be 203.81 cu.ft. and this times the revolutions per minute or 132 = 26,900 cu.ft. Thus this fan produces $\frac{110{,}000}{26{,}900} = 4.08$ times its own cubical contents of air.

This fan has quite a number of blades, some short and some long. I do not know whether there is any advantage in the principle of long and short blades; but I am sure there is considerable benefit in putting in a great number of blades. D. W. Evans of Pittston, Penn., has constructed a fan with numerous blades, their depth being only 5 per cent. of the diameter of the fan. These blades are attached to a rim and central plate, at an angle of about 30 deg. This fan also produces about four times its own cubical contents per revolution, and should be put on the market.



Out on the dump will go your job and mine

How About It?

Written Expressly For "Coal Age"

By BERTON BRALEY

Joy in Berlin

Your job and my job—how much do they mean?
What is our place in the wartime machine?
Are we essential, and do we produce?
For, if we don't, we are simply no use;
Worse, we are brakes that impair and impede,
Hampering progress and vigor and speed.
If we don't fit in the mighty design,
Out on the dump will go your job and mine!

Your job and my job—how well are we placed?
What do we represent, Service or Waste?
Miner and manager, checker and clerk,
How are we handling our share of the work?
Slackers aren't lasting long, over the foam,
This is no time to have slackers at home,
We must be faithful as soldiers in line
Else there's a finish for your job and mine.

Your job and my job—the Nation demands
All we can do with our heads and our hands.
Don't think this war is for others to win,
You and I, brother, have got to fit in;
Each hour we loaf and each task that we slack
Weakens the force of our country's attack,
There is rejoicing far over the Rhine
When we let up upon your job and mine!

Your job and my job—they're worthless and vain
Save as we labor with muscle and brain,
Striving to serve at the top of the breast,
Each of us toiling his hardest and best.
Let us be part of the great honor roll,
Soldiers who fight with the Army of Coal,
Giving our all with a zeal that is fine,
Your job and my job for your land and mine!

The Cost of Coal

SYNOPSIS—*Many factors enter into the expense of producing coal. Some of these are capable of decided reduction from present averages. Others, such as the cost for labor, may be reduced through stabilization. Intensive mining would result advantageously to all concerned.*

FOR analysis, the cost of coal may be divided into promotion, royalty, equipment, labor, distribution and profits. Promotion comes too cheaply, general opinion to the contrary notwithstanding; but the service rendered is small. While, if properly performed, the direct charge for promotion would be increased, thousands of dollars paid in litigation now charged to "cost," and many more thousands considered a legitimate hazard of mining, would be cut off the price of fuel.

To make this economy it is necessary to employ an attorney of recognized standing, an experienced operating official, and a competent engineer. These three should be given definite instruction to include in all deeds, specifically, all rights necessary to mining and prospecting, including release from all damages resulting, so written as to be legally defensible. At no later time can these rights be so cheaply acquired, and if they can be had in no other way the property should be purchased in fee simple.

During the term of the option the mineral should be thoroughly prospected. My experience would dictate a prospect to each 100 acres. This provision alone would have saved in the past millions invested in comparatively worthless lands. A property survey (if extensive, on a triangulated base) should be made, the field locations compared with title plots and all reservations definitely described and located. Property which has been surveyed in recent years should be purchased by the acre, according to the company's location, while parcels which have not been measured within a half century should be purchased in the lump. The cost of all this will be recovered in the royalty.

Preliminary Knowledge Is Important

Before any attempt is made to develop, a topographic survey should be imposed on the property map, showing all buildings, streams, highways and surface contours less than 100 ft. above the topmost bed of coal. The entire field should be projected for mining so as to determine where and how many openings shall be made. This will save thousands of dollars frequently wasted by haphazard location of mines and improper projections.

From the data collected there can be determined the probable life of the field and the net acreage, after deducting barren, unmerchantable and unrecoverable coal. By use of these two factors the amortized royalty per ton can be calculated.

By recognition that fuel is one form of wealth which can never be replaced, and that rather than force its exploitation the process should be discouraged, society can do its bit by exempting all undeveloped coal from taxation. On the other hand, developed coal should be taxed enough to stimulate its prompt recovery, and a surtax should be charged against lost coal in exhausted areas, to force thorough mining.

Before striking a pick the last detail of a proposed mine should be determined and the work should be developed in logical order. First comes the railroad, then the village with water-works, store, etc., then the mine and so on. A modern power plant designed to utilize the lowest grades of near-fuel is required. A mine too small for a power plant of advanced design should purchase its power, and a power plant with antiquated equipment should be scrapped. Electric distribution should by all means be employed.

Delays for Supplies Are Expensive

Where a well-stocked supply house is not maintained, much money is lost in waiting. On the other hand, where one is handy it is apt to be wasteful. A careful check on all supplies and small tools will well repay the expense; every old machine part should be exchanged for a new one, and the worn part should then be examined by a responsible man and refitted, or put in the junk shed. Please note the shed; the tons of junk lost or stolen, if known, would be staggering.

Mine tracks are too light, too poorly graded and aligned, and the bonding is "rotten." Heavier rail and the same track maintenance that a railroad receives would pay big dividends. A pit for annealing old rail would help cut expenses. Why the rail on main hauls is not welded for bonding is a mystery; there are no temperature changes for which to allow.

Mine repair shops as a rule depend too much on hand labor, and I believe large companies lose by not doing more rebuilding for themselves. Large companies should produce their own timber, sand and crushed stone. Possibly a brick kiln would pay.

Small mine cars and few of them (to say nothing of obsolete trucks) is the rule, I believe, because the miners' time seems to cost nothing to the operator. Cars should be plentiful and placed promptly by locomotive. Without wearisome listing, I know of few mines that use enough machinery or have enough of the kinds they do use. An extra machine, as well as repair parts, is always an economy.

The tracks under the tipple should be graded so as to get a free movement of cars in the winter. In cold climates fills rather than cuts on all outside grading will save much labor. I must confess a leaning toward the rotary dump of full trip capacity.

Insurance can be saved by fireproof construction. This need not necessarily be expensive. To get a 100 per cent. return on the investment, all equipment should be operated as nearly 24 hours a day as necessary repairs and overhauling will permit. I know how hard it is to operate a night shift. But why a night shift at all? Take a hint from those industries which must operate continuously and have an early morning and a late afternoon shift; then change shifts each week. Don't forget depreciation and obsolescence and charge enough therefor.

Insufficient equipment and inadequate supervision are responsible for many inefficiencies in coal mines, rather

than the basis of payment. Intermittent operation has been caused by an insufficient car supply and an excessive number of mines. The present high earnings of coal miners are due to the establishment of rates which would give an average miner a living under spasmodic working conditions. In order to correct these it will be necessary to insure full-time work. I expect our Uncle Sam will take care of the car supply; and if the Fuel Administration takes full advantage of its powers before normal industrial conditions are resumed, the superfluous mines will have been wiped out.

In order to radically reduce the cost of digging coal, the change will probably have to be "camouflaged" to avoid serious disturbances. I would suggest a task and bonus system. All men on a day basis and many "company" men can be cut off and the work done on idle days, thus steadying the employment, if necessary. A wage must always be sufficient to keep an adequate working force. For mine work, I imagine we must pay average wages for the class of men desired, plus something to overcome living conditions.

Welfare Work Is Important

Assuming that most of the work about the mines can be done by unskilled labor, it is necessary to gather statistics to show what common labor actually gets in other industries. To this wage should be added the same percentage figured against mining by insurance companies. Man is a pleasure-loving animal, and the less his culture the more he depends on outside sources for his amusement. This is the reason why the average laborer prefers city employment. To overcome this prejudice another allowance is required. If he is to be held any length of time, so-called "welfare" work must be instituted.

By welfare work I don't refer to the maudlin stuff which now passes muster. Everything attempted by a company should be on a strictly business basis definitely understood by all. The reason the company does thus and so—is because it pays.

I would recommend that the housing (in style and type) be the equal of any found in any "open" town of similar size. The streets should be kept up similarly, and sanitation should be pushed to an extreme. All this can be collected in rent.

Public amusements will pay their own way and should be fostered for men, women and children. Education should be encouraged, especially for adults; this may cost the operator some money, but it will be returned a thousandfold in the increased efficiency and number available of petty officials.

I would caution against trying to get wage increases back in company store profit. A company store operated on a narrow margin, managed by a "merchant," and served by real salespeople, would become one of the greatest assets for goodwill an operator can possibly obtain. I have yet to see that kind of store.

One of the gravest wastes in the coal mines is the use of skilled miners to shovel coal. A real miner is as highly skilled as any kind of mechanic. The normal wage he gets is probably not excessive in comparison with other skilled labor. Instead of spending three fourths of his time at work that any navvy can do, he should act as squad leader to several. On the average, in machine mines, one miner to eight navvies would be about the right proportion. This squad, provided with a mining machine, a gathering locomotive and plenty of cars, would revolutionize the output.

A foreman should be provided for as many men as he can conveniently visit constantly, not once or twice a day. He should be paid more than he can earn as a miner. The general foreman and assistants should confine their attention principally to transportation and supplies, and their duties should be restricted to the inside of the mine. Adequate supervision today is a hard problem, mostly because of the ridiculously low salaries paid, but partly because most practical miners rarely have any education. This takes us back to the school problem.

It would pay any coal company to make a special effort to train officials. An apprentice system, made the avenue to promotion, wherein each candidate would serve about a year in each department, whose activities he will touch in later work, is a necessary innovation.

To be eligible to promotion a certain minimum of schooling, or its equivalent, should be required. For instance, a mine foreman should be able to pass an examination in common school branches; a superintendent should have the equivalent of a high school training; an engineer should at least be able to pass the examination for engineer in the Government service.

The functions of officials above pit boss should be specialized. The system of mining should be left entirely to the engineer and safety to the mine inspector. The superintendent being the instrument through whom they work, both should be superior to the superintendent, and of course more highly paid.

Mining ought to be limited to the highest grade of fuel which is of sufficient quantity to fill the demand. This could be accomplished by requiring the operator to pay the freight on the ash content, plus a graduated penalty on all impurities above a fixed maximum. An operator who could not compete on this basis, if he found it impossible to prepare his product profitably and make it come within the specifications, would have to shut down until exhaustion of better fuels brought his up to grade.

Delivery Expenses Are Heavy

Cross-hauling is a waste recently brought to public attention, but I venture to say that the loss through freight cross-hauls is only a fraction of the loss from competitive retail delivery. Probably the use of waterways would cut the freight charges on coal. Domestic consumers who persist in ordering their fuel during the winter months ought to be penalized.

Sales agents should be abolished. There is no reason why the large consumer and the retailer can not deal directly with the mine operator. A fuel engineer who would be able to specify the kind of fuel best suited to individual conditions and name the producers capable of supplying that grade could be jointly supported by the operators logically contributing to a consuming center.

Finally there must be a profit. Capitol is unconsumed wealth. Without capital our present civilization—well, there would be "no sich animile." Unless we offer an inducement, no one will lay aside any of his production. Not being an economist, I will leave the wages of capital for someone else to settle, and will content myself by saying that it must be enough and should not be more.

To treat so vast a subject requires many volumes and many brains. I have condensed this contribution almost to extinction, and it sounds much more dogmatic than I feel. The points I wish to emphasize are:

Mines are generally opened with insufficient data for an engineer to work intelligently. Lack of surface rights adds an enormous burden to the industry, as it is forced to pay damages on valuations that the operations themselves have largely created. This should be remedied in operating properties as soon as possible and new developments should avoid such errors. Coal mining is not carried on as intensively as it should be. In brief we should adopt modern factory methods. More supervision is urgently needed, and a higher standard should be set. Living conditions must be made to compare with those available in other industries.

How Far Does a Belt Slip?

By W. F. Schaphorst
New York, N. Y.

Not long ago I read the following statement in a technical publication, "It is obvious that the chief wear on belts is occasioned by their swift curling and uncurling motion around the pulleys." It is true that this is possible in belts that contain no internal lubricant. If the belt is dry, the fibers rub against one another with considerable friction, and consequently the wear will be great for the same reason that an unlubricated bearing will wear more rapidly than will a lubricated one. This holds true even with ball bearings. But if the belt is properly treated with a preserving lubricant similar to the natural lubricant that is in the hide while on the animal, the internal wear is small indeed. Experience with dry and treated belts bears out these statements, and I believe the author of the quotation given above will agree with me.

While thinking this over, however, the fact developed that there has been given no formula, in textbooks or elsewhere, for computing the distance a belt slips or creeps in a given time—a year, for example. I thought it might be because the total slip for a year is a small amount—not worthy of much thought—but after doing a little rough figuring my eyes opened to the astounding figures that resulted.

Let us take an example. A 4-ft. pulley rotates at the rate of 250 r.p.m. Its belt does not slip, but the creep is 2 per cent. It is used 10 hours per day during 300 working days in the year. How far does it creep per year?

Multiply the 4 by 3.1416 and then by 250 and we find the pulley travels 3141.6 ft. per minute. Multiply this by 2 per cent. and we find that the belt creeps (this is sometimes erroneously termed "slip") about 63 ft. per minute. That immediately looks like an almost impossible amount, but it is true nevertheless. This is equal to 3780 ft. per hour, 37,800 ft. per 10-hour day, or 11,300,000 ft. per year of 300 working days—a total of 2140 miles.

Does it seem strange now that belts wear out? Isn't it remarkable that belts last as long as they do? And isn't it plain that pulleys should be smooth in order that the wear may be reduced to the minimum? Two thousand, one hundred and forty miles of rubbing even on a smooth pulley is considerable. And if there is any slip on the pulley in addition to the creep the matter is all the more serious.

It must be remembered, however, that a given point on the contact side of a belt is not in contact with the pulleys all the time. During each complete trip of the belt around the pulleys the given point is in contact with one pulley for a short time during which there is a rubbing action to some extent, then the given point is not in contact with anything until it reaches the next pulley, when it again rubs. The greater the distance between shafts, then, the less the yearly slip or creep of the given point. Thus if we could connect a driving pulley on the earth with a driven pulley on a distant star a given point on the contact side might not touch a pulley for several years, even when running at the speed of the belt cited in the example above. Such a belt should last millions of years, were the length of life dependent solely on friction. A short belt, on the other hand, is subject to greater punishment because the given point comes in contact with the pulleys frequently.

To aid in computing the slip plus the creep of a point, taking into account the radii of the pulleys and the distance between shaft centers, I have developed the following rule:

Multiply the "total yearly slip of the belt" as obtained above by 3.1416, and then by the sum of the radii of the pulleys in feet. We will call this amount "A." Now multiply the distance between shaft centers in feet by 2, and to it add the product of 3.1416 multiplied by the sum of the pulley radii in feet. Divide "A" by this sum, and the quotient is the total number of feet a given point slips and creeps in a year's time.

For example, let us assume that in the problem above the distance between shaft centers is 30 ft. and the pulley radii are 1.5 ft. and 2 ft. respectively. What is the total creep of a given point on the contact side of the belt in a year's time?

Adding the radii we get 3.5 ft. Multiplying by 3.1416 we get 11. Multiplying that by 2140 miles we get 23,540 miles, which we call "A." Now multiplying 30 by 2 we get 60, and multiplying 3.5 by 3.1416 we again get 11. Adding 11 and 60 we get 71. Lastly, dividing 71 into 23,540 miles we get 332 miles as the total slip of a given point per year.

For the convenience of those who prefer rules of this kind in the form of an algebraic equation, we have the following:

Yearly slip plus creep of a given point on a belt =

$$\frac{3.1416DNSM(R+r)3.1416}{[(R+r)3.1416+2L]5280}$$

where

D = Diameter of the driving pulley in feet;

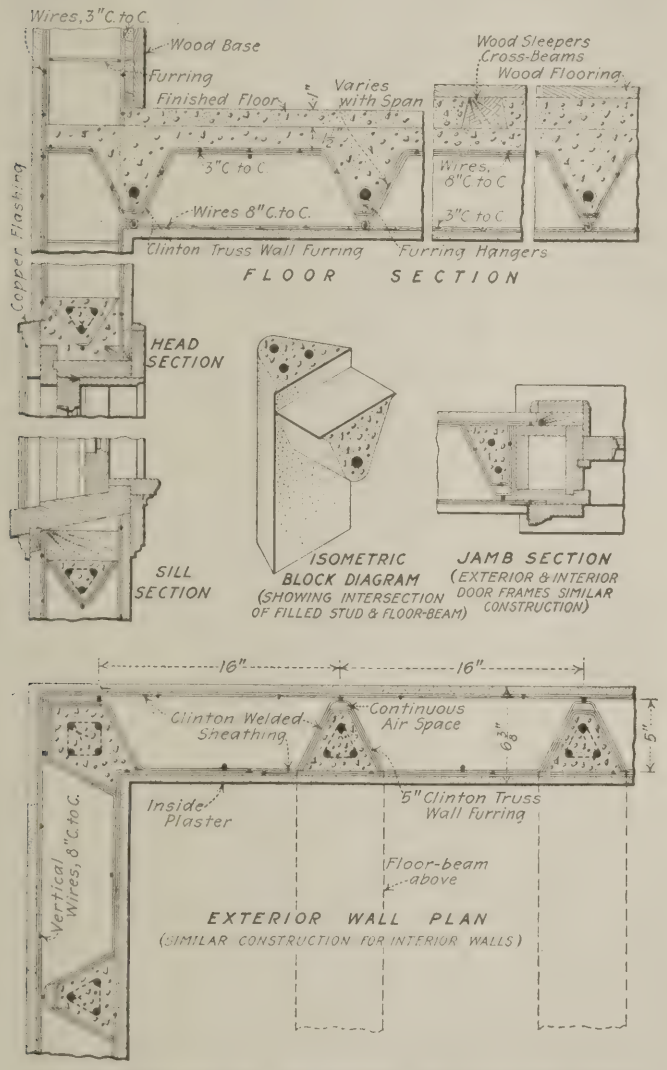
N = R.p.m. of the driving pulley;

S = Slip plus creep of the belt;

M = Number of minutes belt is operated per year;

R = Radius of driving pulley in feet;

r = Radius of driven pulley in feet;



L = Distance between shaft centers in feet.

This, then, explains why belts wear out. It can well be imagined that if a belt is dragged along on even a smooth surface such as found on pulleys for a distance of 332 miles there is bound to be some wear and this would be equal to the yearly wear on the belt.

Two All-Concrete House Designs*

SYNOPSIS—*Forms made of wire cloth, an ingenious way of keeping water from the inside of a concrete house and a system of incorporating precast beams integrally into the house structure are here described.*

THE great need for houses throughout the industrial and shipbuilding centers of the country has led to the preparation of a number of designs providing safe and comfortable homes at reasonable cost and lending themselves, at the same time, to quantity construction. Among these are two embodying somewhat similar details. Both of them plan to use

STUDS AND BEAMS OF FRAME ARE OF CONCRETE POURED INTO SHEATHED WIRE-CLOTH FORMS

concrete or concrete and plaster throughout. They have reinforced-concrete frames with double walls of stucco and plaster, all erected with a minimum use of forms or stages.

Two experimental houses are now being built, in accordance with one of these designs, near a mill of the Pennsylvania Cement Co., at Bath, Penn. Sheathed wire cloth is used to construct the forms into which to pour the concrete units making up the house frame. The type of construction has been named the "Alcho System" and is being developed by Albert Oliver, of the Clinton Wire Cloth Co., New York.

One of the fundamental elements in the design of the house is its triangular reinforced-concrete studs. These studs support on the inside a plaster wall and on the outside a concrete-stucco facing, an insulating air space being left between them. Each stud carries floor and roof beams of similar triangular design, and integral with these beams is a reinforced-concrete floor or roof.

The studs are erected on the concrete walls of the cellar or basement, the forms for the studs being continuous sheets of Clinton welded sheathing, which is a building paper woven into a wire cloth. This is bent to the shape of the studs to be formed, and the concrete is poured inside.

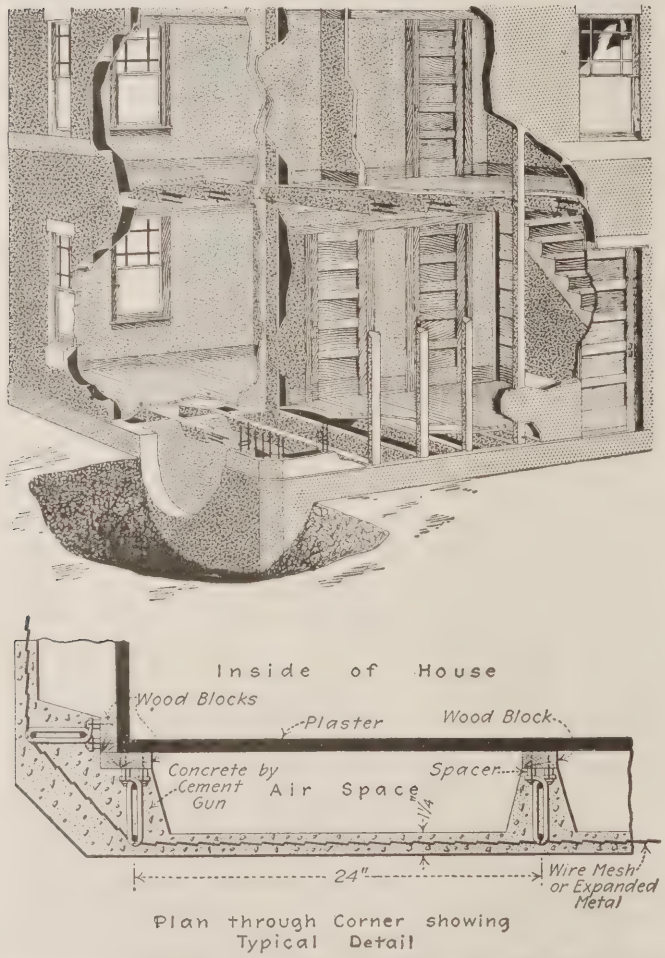
Outside the sheathing are rows of furring rods which project beyond the apex of the stud triangle and to which are fastened the sheathing, making the inside form for the outer wall. This leaves a small air space at each stud, preventing water even at these points from permeating into the wall. The base of the stud also has sheathing against which the inner wall is plastered.

The beams are varied in depth according to the span required. They, too, are cast within sheathing forms, the sheathing being supported on struts during construction. Hangers left in the beams carry furring on which the ceiling is plastered. The floor itself is poured so as to be integral with the beams and can be finished as desired.

The wood-frame doors and windows are detailed as shown in the drawings. The stairs are of concrete, and the partitions are of concrete or plaster applied on wire cloth. The roofing, where the roof is flat, will be of fire-resistant material placed on a concrete slab. It will probably be placed on timber framing where the roof is sloping.

It is intended that the houses now being built at Bath, in accordance with these designs, shall be of poured concrete with hand-plastered walls and partitions. Provision is made, however, for the use of the cement gun in placing the concrete, in which case the studs are turned with the base of the triangle outward to facilitate placing.

In the other type of house, which has been devised by John V. Schaeffer, the president of the Cement Gun Construction Co., Chicago, the studs and walls will be built entirely by the cement gun, while the beams will be precast concrete and the floors will be poured in the usual manner.



On the page following a sketch is shown of the broken corner of a proposed house of the cement-gun type with all elements of construction in view, and a horizontal section through the wall with the details of a characteristic design. This wall structure comprises studs on 24-in. centers integral with a 1½-in. outer wall

*Article entitled "Two New Designs of Concrete Throughout" appearing in "Engineering News-Record," May 16.

and separated from the inside plaster wall by wood blocks fastened both to the studs and to the wall, leaving an interior air cell for insulation against temperature and moisture.

In building the house a cellar is first excavated, and cellar walls are built in the usual manner except that recesses are left in which are set the precast joists for the first floor, spaced on 24-in. centers to match the studs. On this frame as a platform subsequent construction is carried on A temporary timber framework is then erected on the platform, and the wood blocks of the studs are then set up. The reinforcement, as shown in the floor section herewith, is attached to these wood blocks before they are erected.

After the reinforcing fabric of the wall is placed, the walls and studs are shot with gunite from cement

WALLS AND STUDS ARE SHOT WITH THE CEMENT GUN AND BEAMS ARE PRECAST

guns. When the upper floor is reached, precast beams are placed with protruding reinforcement which is intertwined with the reinforcement of the studs. Connection is made by the use of the cement gun. Plastering, or wire mesh, is then placed on the inside wall and belt courses are shot around the tops of the studs so that all air spaces are isolated at each floor, and after the plastering is in place each air space or cell is a unit. This is designed to prevent circulation of air or migration of vermin.

To provide the backing, against which the cement-gun concrete is formed, several methods have been proposed such as the use of separate unit forms which can be used over and over and the employment of sheathed wire fabric. In the latter case the fabric, being inside the wall, can be left in place.

The system followed in either scheme of operation can be varied to suit the details of the layout and the architectural treatment. It is stated that reliable contractors have submitted estimates of cost, which though higher than are customary for lumber construction compare favorably with the actual cost of the cheaper type of brick house with wood floors. The method is less costly than that followed in the erection of most fire-resisting buildings.

Shipments of Anthracite for May, 1918

The shipments of anthracite for the month of May, tion at Philadelphia, amounted to 6,887,256 tons against 6,917,525 tons in May, 1917, and 6,368,373 tons in April of this year. The shipments last month, therefore, show 1918, as reported to the Anthracite Bureau of Informa- an increase over April of 518,883 tons, but a decrease as compared with May a year ago of 30,269 tons. This decrease as compared with last May, under ordinary conditions, might be considered insignificant, but a serious aspect is given to it by the fact that the shipments of the domestic sizes decreased 174,896 tons, whereas the shipments of steam sizes increased 144,627 tons, all of which increase and more was recovered from the culm banks, and was not fresh-mined coal. In May, 1917, the shipments of domestic sizes amounted to 4,707,246 tons, or 68.04 per cent. of the total; last month the shipments of domestic sizes amounted to 4,532,350 tons, or 65.8 per cent. of the total. The shipments of steam sizes increased from 2,210,279 tons, or 31.96 per cent. of the total in May, 1917, to 2,354,906 tons, or 34.2 per cent. of the total in May of this year.

Compared with April of this year the shipments of domestic sizes increased 283,787 tons, or 6.7 per cent., while the shipments of steam sizes increased 235,096 tons, or 11.1. The decrease in the shipments of domestic coal, all of which is fresh-mined, as compared with last year, and the relatively smaller increase over April as compared with the increase in steam sizes, are due entirely to the inroads made upon the labor supply in the anthracite region, chiefly by the activities of munition plants and other war industries, several of which are located immediately in or adjacent to the mining districts. Some of these establishments are working on contracts of a "cost-plus" basis in which the cost of labor or of materials is of little importance, as profits on any costs are guaranteed, but their action in taking the labor from the mines is threatening the comfort and safety of the communities dependent upon the anthracite mines for their winter fuel.

Distributed by carrier companies the shipments during May were as follows:

	May, 1918	May, 1917	Coal Year, 1918	Coal Year, 1917

Safety, Direction and Warning Signal

By R. H. COULSON
20 Hornby St., Wigan, England

SYNOPSIS—*Most hoisting accidents arise either from a temporary lapse of attention on the part of the engine driver or from a mistaken position of the reverse gear. An apparatus is here described that is simple and positive in operation. Through a display of light signals it tends to lessen the accidents arising from either or both of the causes mentioned above.*

ANY IMPROVEMENT that can be devised for the purpose of preventing winding accidents will meet with the approval and commendation of the mining community. Undoubtedly the last 25 years have witnessed the introduction of great advances in detail in the operation of and accessories for hoisting engines. Nevertheless hoisting accidents continue to be reported, and many of them, no doubt, have occurred because the engineman in charge started with the reverse gear in the wrong position, due to momentary neglect, or having his attention directed elsewhere at the critical moment. The importance of safeguarding the hoist will be realized when it is remembered that in addition to it being employed for the purpose of raising the mineral, at least twice each day the lives of all the men employed underground depend upon the successful working of this equipment.

Successful Apparatus Was Designed

It was to the end that greater safety might be secured that the agent of the Collins Green Collieries, in Lancashire, some time ago suggested to the manager, Thomes D. Watson, that he might go into the matter of attaching some mechanically controlled arrangement to the hoisting engines so that the engineman in charge would know at any time whether his reversing gear, when starting or stopping, was in the right or wrong position. The agent outlined what was really required, and after working some time on the problem Mr. Watson devised a fairly successful apparatus. His agent further suggested that if he could make a warning signal sound an alarm at any predetermined point to warn the engineman that he should shut off steam it would be a still further improvement. This was fairly easy to accomplish on the existing arrangement, and the apparatus ultimately devised will tell the engineman in charge whether he is right or wrong with his reverse gear. The device is called the safety direction and warning signal and is intended for use in connection with hoisting, haulage and other machinery in which movement is to be reversed or stopped at regular intervals.

The apparatus gives a special signal, if needed in addition to any other indication, to warn the person in charge of the machinery that a certain predetermined point has been reached and also to show that the reversing gear is or is not in such a position that the intended depth or distance may be exceeded. The apparatus consists of three screens, rectangular, curved plane, or circular in form, with suitable gearing for altering the relative positions of two of them in relation to each other, and to the third, which is a fixed screen. Each of these screens is perforated in such a manner that at the predetermined point or points the light from a lamp placed behind becomes visible, either clear or through colored glasses, or other media, as may be desired, to the person in charge of the machinery. If desired a bell can be made to ring on approaching visibility. One of the movable screens is operated through suitable connection with the reverse gear; the other movable screen is moved through suitable connections by the drum or machinery shaft.

How the Lights Work

The latter movable screen is provided with red and green glass and is worked by a rack in mesh with a pinion fixed on an extension of the clock-face indicator spindle. Two lights are displayed, "red" and "green," but only one of these is visible at one time, the other being hidden by the screen actuated by the reversing gear. Near the end of the wind, at least two revolutions of the drum before the actual finish, a red light appears and remains visible until the reverse gear is put in the proper position for the next wind, when the red light disappears and the green light appears. This green light gradually disappears on starting the hoist and after the first two revolutions becomes invisible. After three-quarters of the wind has been completed (or any predetermined point reached) a small red light gradually appears, warning the engineman to shut off steam, when the small red light slowly disappears and when within two revolutions of the landing the larger red light appears and is full on at the completion of the wind. This operation is repeated as often as a wind takes place.

The glasses fixed on the movable screen actuated by the drum gear can be adjusted by a thumb screw arrangement to suit any position of the wind that is required and any reasonable number of glasses, if so desired, can be attached to suit any landing arrangement.

A horizontal depth indicator devised by Mr. Watson is placed under the center of the fixed screen. In this depth indicator the figures move and the pointer remains stationary, and on completion of the wind the end of the movable indicator comes to rest under the center of the red light.

Where great depths have to be shown, the indicator can not be easily seen. With this depth indicator the engineman has only to keep his eye fixed on the center of the depth indicator both for warning signal and depth indication.

This warning signal apparatus can be used for main rope and main and tail rope haulage (having fixed points to go to and from) whether worked by steam or electricity. It can be arranged to suit any number of landings, each being denoted by a different colored glass.

The secretary and agent to the Lancashire, Cheshire

and North Wales Enginemen's and Boilermen's Federation (Thomas Watson) who visited and examined a model of the apparatus, in a written communication says:

I have carefully thought over the merits of your invention, and I am fully satisfied it is a decided improvement on all appliances brought out up to the present for making overwinding less frequent. For instance, there are two distinct features associated with your invention not peculiar to others.

It gives visible warning to winders in a most clear, definite manner when engines are exceeding speed at various important points and similar warnings also in the event a winder attempts to start the wrong way; the whole construction being both simple and moderate in cost. Certainly I can honestly say and it can be verified by those having an extensive knowledge of overwinding accidents, that at least 50 per cent. take place through starting the wrong way, which without doubt your contrivance will reduce to a minimum.

If by a stud arrangement a bell is made to ring when the red light was approaching visibility, introducing sound to remind sight, bringing another special sense into operation, it would perhaps add to its utility.

The new device has also been examined by William Forshaw, assistant secretary and agent to the Lancashire, Cheshire and North Wales Engineers' and Boilermen's Federation, and the following is an excerpt from his letter:

From a winding engineman's point of view it (this apparatus) appears to have no objectionable features, while it has distinct advantages. It will, I consider, be helpful to the engineman and will conduce to the safety of life and property by tending to reduce overwinding accidents due to starting the engines in the wrong direction.

In addition to the foregoing and others the apparatus has been examined by the enginemen at the colliery where Mr. Watson is the manager, and all express their appreciation of this apparatus and its simplicity. One person who examined the device has no hesitation in saying it was the "Engineman's Friend."

Referring to the illustrations of the safety, direction and warning signal, Fig. 1 shows the apparatus ready for descent, while Fig. 2 shows it ready for ascent. Fig. 3 shows the rack screen which carries the colored glasses. Fig. 4 shows the movable screen in relation to

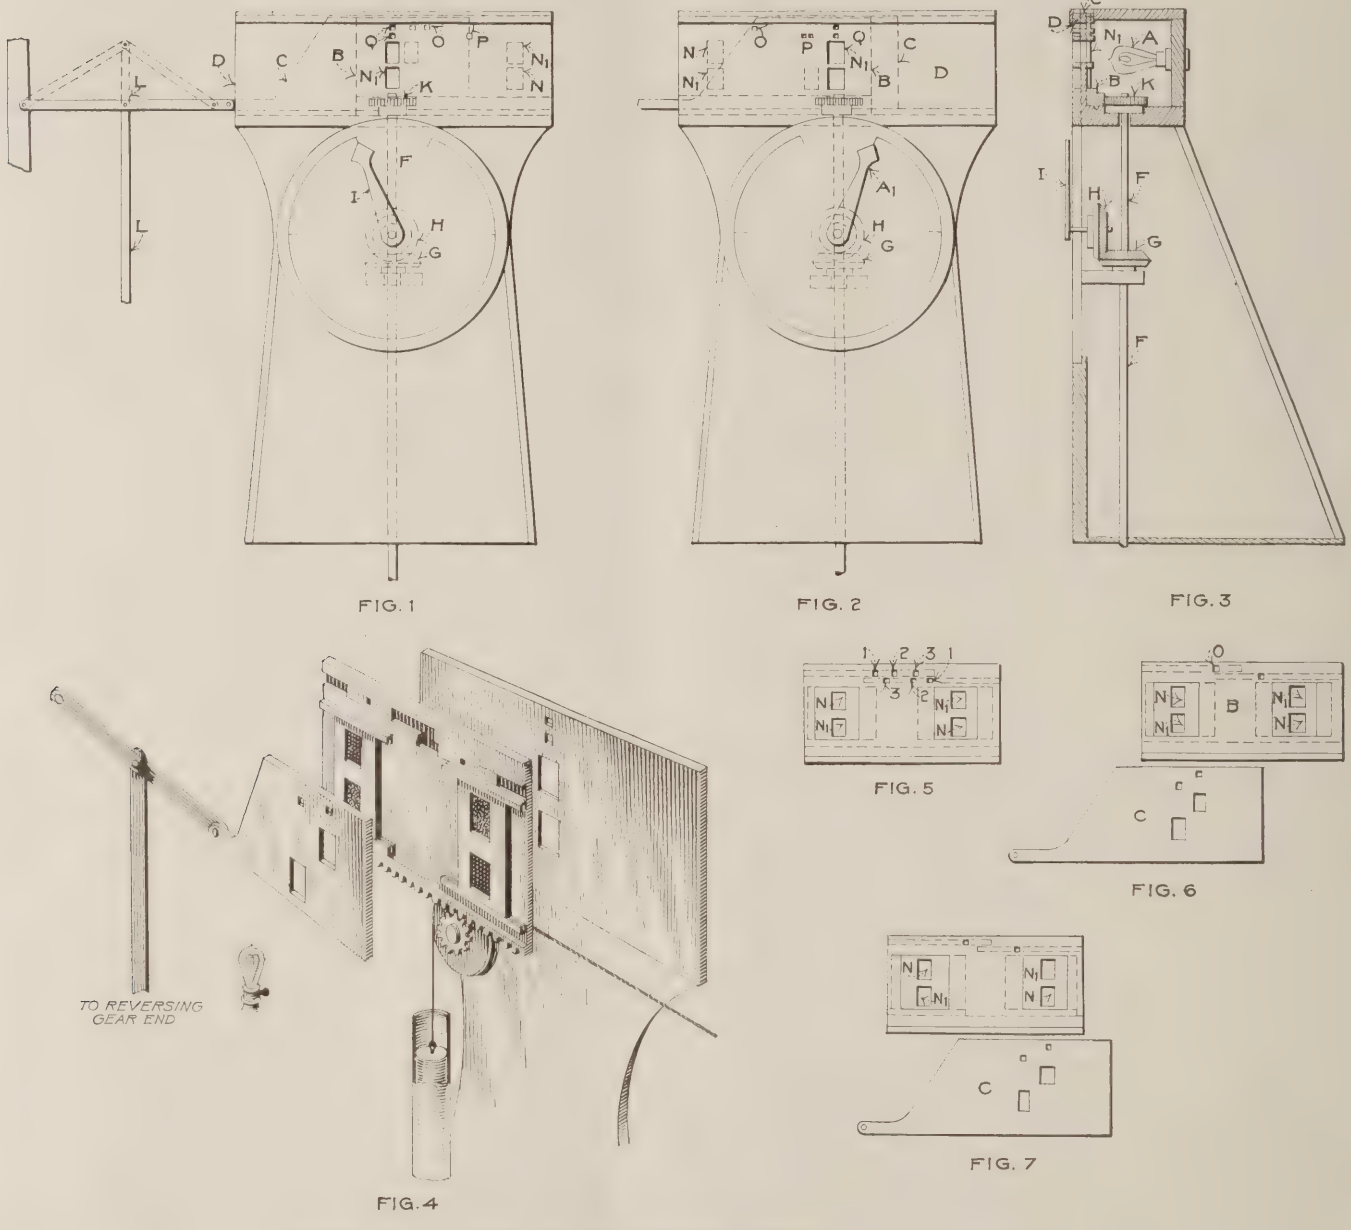

FIG. 1 FIG. 2 FIG. 3

FIG. 4 FIG. 5 FIG. 6 FIG. 7

FIGS. 1 TO 7. DETAILS AND VARIOUS VIEWS OF THE APPARATUS

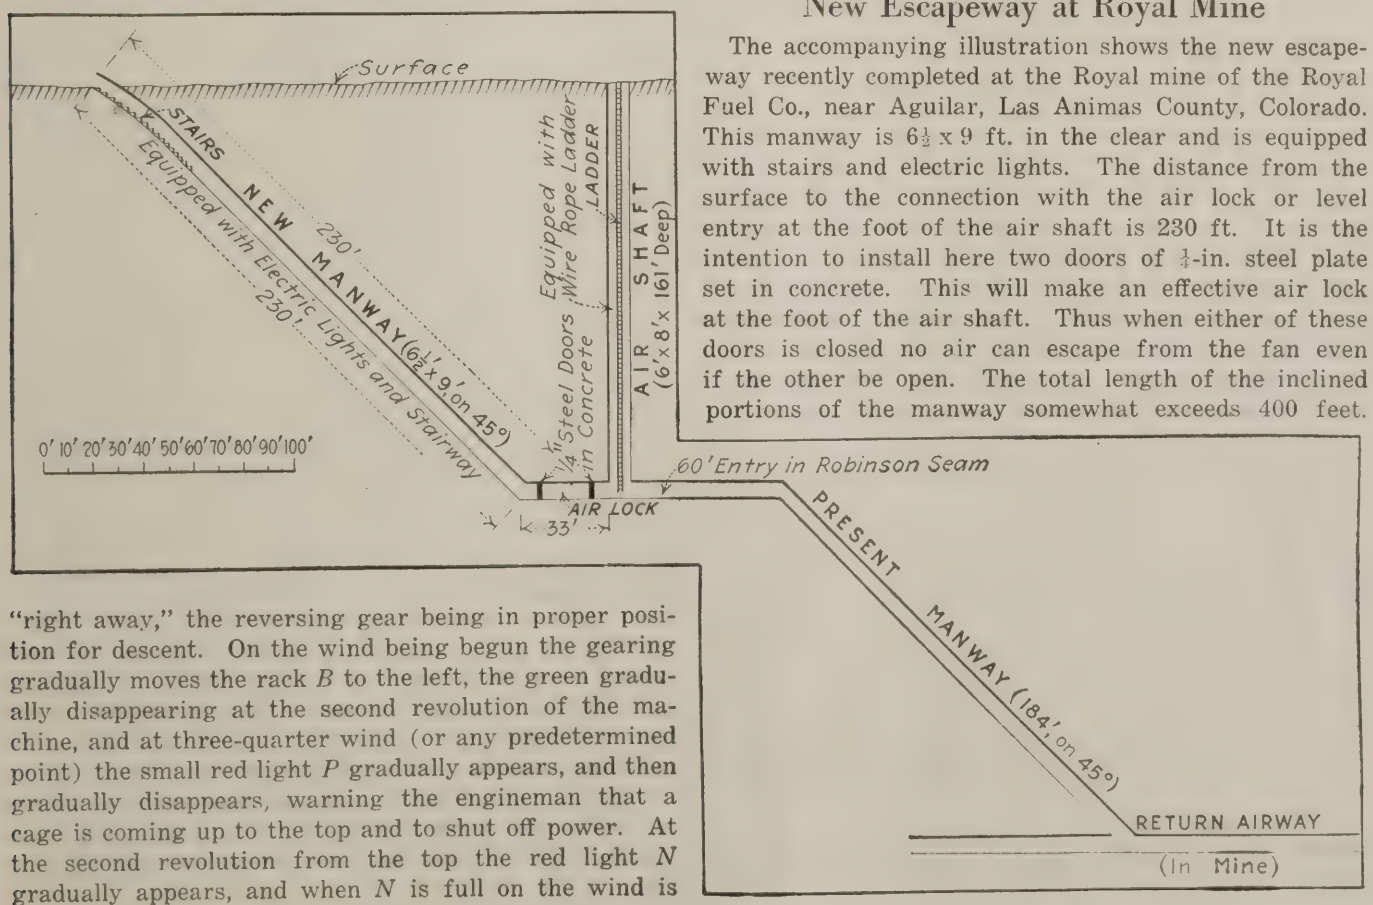
the reversing gear position. Fig. 5 shows the rack screen with glasses separately. Figs. 6 and 7 show the movable screen in relation to the reversing gear positions. Fig. 3 is a section of the apparatus as shown in Fig. 2. Fig. 5 shows a rack screen for haulage underground with a starting and stopping point with three landings of shunts between them, each shunt being denoted by different colored glasses, and Fig. 4 shows the apparatus fixed to a cord indicator ready for an ascent.

Examining the accompanying figures it will be seen that the device consists of the lamp *A*, the screen *B*, moved by means of the spur gearing *K* meshing with a rack carrying a screen with glasses, and as the cage moves up or down the pointer *I* is actuated by the shaft *F*, through the bevel gears *G* and *H*. *C* is the screen operated by the toggle lever *L* from the reversing gear. *D* is the front screen which is fixed. This, as shown in Figs. 1 and 2, is of such length as to allow the other two movable screens to work behind it. *B* is the rack screen, shown clearly in Figs. 3 and 4. It has guides whereby the openings filled with colored glass can be regulated and adjusted by hand when required. The colored glasses *N and* N_1 are respectively "red" and "green," and appear when the perforations in the screens coincide.

Small Lights Show When Power Can Be Shut Off

The little glasses *P* and *O*, colored red, alternately appear opposite their respective openings and show when the cage has reached such a point that the power can be shut off. This forms a warning signal.

The apparatus is shown ready for descent in Fig. 1. The screen *B*, as shown, has the bottom perforations opposite, and the green glass N_1 shining through shows "right away," the reversing gear being in proper position for descent. On the wind being begun the gearing gradually moves the rack *B* to the left, the green gradually disappearing at the second revolution of the machine, and at three-quarter wind (or any predetermined point) the small red light *P* gradually appears, and then gradually disappears, warning the engineman that a cage is coming up to the top and to shut off power. At the second revolution from the top the red light *N* gradually appears, and when *N* is full on the wind is complete. The rope cage is now at the top. By changing the reverse gear the screen is moved to the position shown in Fig. 6, and the apparatus is ready for another wind, as shown in Fig. 2.



Precisely the same operation takes place in the reverse direction, but instead of the small red light *P* gradually appearing the small light *O* gradually appears, warning that the other cage is coming to the top and it is time to shut off power. If so desired electric contacts at *O* and *P* can be fixed so that when these lights appear sound can be made to remind sight.

The screen *D* can be made of sheet iron $\frac{1}{8}$ in. thick; screen *C* of sheet iron $\frac{1}{16}$ in. thick; screen *B* of the same material $\frac{1}{8}$ in. thick, with shoes for glasses, rack and spur wheel of cast metal. The lamp chamber is preferably enameled white so as to give better results. As to method of lighting, any lamp is suitable for the apparatus.

The following claims of advantage are made for this device: The small red light gradually appearing and disappearing warns the engineman that it is time to shut off steam. The larger red light gradually appearing warns the engineman of nearing completion of wind, and when full on tells him that the hoist is finished. The larger red light warns the engine driver of the danger of restarting his machine until movement of reversing gear obscures the red light and shows the green light. The green light informs the hoistman that the reversing gear is correct for restarting the machine when the signal is given. The whole arrangement is simple, compact, inexpensive and has few parts to get out of order. The inventor acknowledges his indebtedness to his fellow officials and workmen for criticisms and suggestions.

New Escapeway at Royal Mine

The accompanying illustration shows the new escapeway recently completed at the Royal mine of the Royal Fuel Co., near Aguilar, Las Animas County, Colorado. This manway is $6\frac{1}{2}$ x 9 ft. in the clear and is equipped with stairs and electric lights. The distance from the surface to the connection with the air lock or level entry at the foot of the air shaft is 230 ft. It is the intention to install here two doors of $\frac{1}{4}$-in. steel plate set in concrete. This will make an effective air lock at the foot of the air shaft. Thus when either of these doors is closed no air can escape from the fan even if the other be open. The total length of the inclined portions of the manway somewhat exceeds 400 feet.

SNAPSHOTS IN COAL MINING

MINERS AT WORK IN A THICK SEAM OF ANTHRACITE

COAL-LOADING PIER AT NORFOLK, VA.

GENERAL VIEW OF DORRANCE COLLIERY, LEHIGH VALLEY COAL CO., WILKES-BARRE, PENN.

NO. 3 TIPPLE OF NEW RIVER COLLIERIES CO., ECCLES, W. VA.

READERS are invited to submit photographs suitable for reproduction in the pages of COAL AGE. Views of surface plants, scenes underground and snapshots of coal-cutting and conveying machinery are especially desirable. Good photographs will be paid for liberally, and whenever requested will be returned after they have been used. If you are proud of your company buildings, surroundings and equipment, send in some photographs so that COAL AGE readers may see why.

PARTIAL VIEW OF TIPPLE AND WORKS AT THE MINES OF THE VICTOR-AMERICAN FUEL CO., DELAGUA, COLO.

To Classify Industrial Users of Coal

All industrial concerns using 500 tons or more of coal annually are to be classified on the so-called preference list of the War Industries Board. In order that no hardships may result all concerns are urged to return at the earliest possible moment the questionnaire which has been sent to them by the Fuel Administration. Dealers are not to be allowed to add increased freight charges to coal transported prior to the increase in rate. The Fuel Administration expects to penalize severely any dealer who adds the freight rate increase to coal on which this increase was not actually paid.

Explains Order Regarding Railroad Fuel

"The Government prices for coal are maximum prices, and it follows as a matter of course that any consumer including the railroads may purchase for less than the Government price provided it is mutually agreeable. The preferential car supply has been discontinued and will not be a consideration of any contract or understanding." Dr. Garfield made this statement in clarifying the intent of the order covering railroad fuel.

Large Tonnage to Northwest and Canada

A total of 28,000,000 tons of bituminous coal will be handled through Lake Erie ports to the Northwestern States and to Canada, it has been announced at the Fuel Administration. Of the total, 24,000,000 tons will go to the Northwestern States. Every effort will be made to expedite the movement of the Northwest supply so that early diversion of coal may be made to Ohio and Michigan. This will obviate the difficulties of last year when the supplies for the last-mentioned states did not become available until late in the fall.

Shipping Board Proud of "Tuckahoe"

The Shipping Board is proud of the performance of the "Tuckahoe," one of its new colliers. The ship was built in 37 days. During the first month that it was in service, ending June 21, it took four cargoes of coal from Norfolk and Baltimore to Boston. The four cargoes aggregated 19,000 tons. Two round trips a month have been the average performances of steam vessels engaged in the New England coal-carrying trade. One of the round trips of the "Tuckahoe" was made in seven days.

Tidewater Coal Must Be Dumped Immediately

Coal for tidewater must be dumped immediately, the Fuel Administration has ordered. Some shippers have delayed dumping in order to hold the coal for bunkering, thereby allowing them to take advantage of the higher price.

Priority in Labor Supply

Priority in labor supply soon is to take definite form. Labor probably will be supplied in the following order: Shipbuilding activities; operation of railroads; production of coal, coke, oil and essential minerals; munition manufacture and other supplies for Army and Navy use. This classification will be extended at length, but some time probably will be required.

To Restrict Coal for Use of Breweries

Coal for breweries probably will be reduced to 50 per cent. of the consumption during a normal year. Conferences to this end are in progress. Pooling of the manufacture of beer is meeting with favor. It is believed that several hundred breweries located at a distance from a coal supply could be closed, thereby confining the making of beer to plants which could be operated more economically so far as fuel is concerned.

Weekly Production Statistics

Previous performance in the entire history of coal mining in the United States was exceeded again during the week ended June 15, when production reached 12,571,000 short tons. This compares with a production of 11,434,000 short tons in the corresponding week of last year, which in itself was a record at that time. The daily average production for the week ended June 15 was 2,095,000 net tons. This is regarded as a truly wonderful accomplishment when it is considered that serious car shortage still exists; that thousands of the most productive operatives have been taken by the draft and that labor conditions generally are in a demoralized state.

Anthracite production for the week under review showed an increase of 3 per cent. Shipments aggregated 41,960 cars. This is the best showing that has been made in many weeks.

Beehive coke production for the week ended June 15 was 658,000 tons. This is an increase of 3.5 per cent. over the week preceding. Byproduct coke production

continues to hit its stride around 89 per cent. of full-time capacity. Production for the week under review was 484,290 tons. Extensive repairs to plants continue as the principal limiting factor.

The percentage of full-time output during the week ended June 8 was the highest ever recorded. During that week, the mines of the country were operated at 82.3 per cent. of their full-time capacity.

Telegraphic advices to the Fuel Administration covering output during the week ended June 22 show a slight decrease. It is believed that the remarkable performance of the week ended June 15 will be the peak of production for some weeks to come.

The figures referred to in the foregoing are estimates made by C. E. Lesher, the geologist in charge of coal statistics for the United States Geological Survey.

Rates Equalized on Bunker and Cargo Coal

Railroad rates equalizing charges on bunker and cargo coal to all ports have been issued by the Interstate Commerce Commission. The commission sees no justification during the present emergency for lower rates on bunker coal than on cargo coal originating at the same point and delivered to the same vessel.

Coal Prices Changed in Texas

Prices for bituminous coal and lignite mined in Texas are as follows: All bituminous coal, except that produced in Erath, Palo Pinto and Young Counties, run-of-mine, $4.25; prepared sizes, $5.05; slack or screenings, $2.25.

Erath, Palo Pinto and Young Counties, run-of-mine, $3.40; prepared sizes, $4.20; slack or screenings, $2.25.

All lignite, run-of-mine, $1.55; prepared sizes, $1.75; slack or screenings, $1.

The regular allowance for wage increase may be added. In the case of bituminous operations, summer discounts must be made.

Rigid Inspection Leads to Cleaner Coal

Out of 621 inspections made at the instance of the Fuel Administration during the week ending June 22, 390 showed that coal was being prepared improperly. No case was sufficiently flagrant to cause the closing of the mine. The Fuel Administration finds, however, that "the rigid inspection is having constructive results in securing cleaner coal and thus conserving transportation and time."

To Discontinue Preferential Car Supply

Discontinuance of a preferential car supply for railroad fuel, effective June 24, has been ordered on the Pennsylvania lines and on the Baltimore & Ohio. The principal is to be extended to other roads as rapidly as possible, in accordance with a recent agreement.

New Coke Prices Announced

Additional coke prices have been announced as follows: Beehive ovens, in Cumberland County, Tennessee —Blast furnace, $7.25; 72-hour selected foundry, $8.25. Beehive ovens at Ansted, West Virginia—Blast furnace, $7; 72-hour selected foundry, $8.

To Bring Mexican Labor Into United States

Immigration regulations have been suspended so that Mexican labor may be contracted and brought into the United States for specified occupations, which includes lignite coal mining.

Fuel Oil Users Urged to Buy Early

The Oil Division of the Fuel Administration is urging plants which operate on fuel oil to fill their available storage now and, if possible, to create a reserve which could be used next winter. Only in this way will plants be protected from emergencies that may arise next winter. The heaviest demands will be made on petroleum products and the greatest difficults are likely to be experienced as regards railroad congestion.

At the present time, it is pointed out, the oil industry is getting exceptionally good service out of the oil transportation equipment. Tank cars are moving as high as 300 miles a day now, as compared with the general average of under 30 miles per day last winter. This means that an immense amount of fuel oil can be delivered now, as compared with what can be handled under the handicaps of next winter's weather conditions.

New Prices for Anthracite at Lake Docks

To provide for the increase in freight rates and the cost of handling at the docks, new prices on anthracite at Lake Superior and Lake Michigan docks have been ordered as follows: Broken, $10.20; egg, $10.10; stove, $10.35; nut, $10.45; pea, $8.80. The prices are subject to the summer reduction of 30 cents.

Brief Washington Notes

Martin Gerry has been appointed fuel administrator for Montana. Mr. Gerry is a civil engineer and resides at Helena.

T. B. Davis, president of the Island Creek Coal Co., has been made chairman of the National Coal Association's committee on mine supplies and priorities.

Cement plants have been assured of a sufficient fuel supply to handle all production needed for war requirements and for other demands of exceptional importance.

W. W. Miller has been appointed fuel administrator for the State of Washington. He succeeds David Whitcomb, whose appointment as executive secretary to Dr. Garfield is announced.

For violating the regulation with regard to bunker coal, the Penn Fuel Co., of New York, has been deprived of its license by the Fuel Administration. Further action is to be taken by the Department of Justice.

Purchase of 125,000 acres of coal land by the Government and the purchase of the Virginian Ry. are provided in a bill introduced by Senator Lewis of Illinois. The field would be operated by the Government with the idea of supplying the coal needs for the Navy and the Army.

THE LABOR SITUATION

EDITED BY R. DAWSON HALL

General Labor Review

There is a growing sentiment in favor of a distinction being made between essential and less essential industries in the operation of the draft. It is stated by the National Coal Association, which has just completed a survey of the situation, that by Sept. 1, when the second draft calls will be completed, more than 2,000,000 men will have been drawn from the ranks of labor in the coal-producing states for service in the United States Army. It is becoming increasingly hard for those who are carrying the industrial burden of the war to do so in the face of the depletion of the working forces. Meanwhile the less essential industries are continuing to operate under as many privileges as to draft and labor as the essential industries, under few or no restrictions as to production and under absolutely no restrictions as regards price of product.

Anthracite operators unable to meet the requirements of the coal market by getting new men, by hiring women or boys below the age limit, or by a suspension of the Gallagher bill, are trying to increase their tonnage by decreasing absenteeism and inducing miners to put in a full day.

The Susquehanna Collieries Co. in the Mt. Carmel-Shamokin district called together 20 to 50 of its best miners in every colliery and presented the coal situation to them in all its perplexities. The Susquehanna officials requested the men to work a full eight-hour day. The company's officers declared that they wished to see the miners making big wages and would do all they could to aid them in that endeavor.

PROMISE TO WORK STEADILY AND WITH ENERGY

Nearly all the men pledged themselves to work a full eight-hour day in the cutting of coal. They were assured that the company would not fail to supply cars as fast as they were needed. The conference also took up the question of the slow-work days following every pay-day. The company expects shortly to announce a system of bonuses to be paid to the men who do most toward increasing coal production.

Pledge cards, which earnest mine workers started ten days ago to circulate among their fellows, are already showing their value. At every mine where they have been used, it is noted that the average of absenteeism has appreciably decreased, with the result that the men, as a body, are working much more nearly 100 per cent. time. There is still a wide gap, however, between the nominal 48 hours per week per man and the actual time made.

Statistics go to show that the war calls upon the anthracite army of workers have had the effect of bringing down the average effectiveness of the whole body of labor engaged in the anthracite industry. This is partly because a large number of men, new to the work, have come in, partly because there is an abnormally large turnover in the labor force, but chiefly owing to the fact that the largest drain has been from men between 20 and 31 years who, in the natural order of things, are more capable than others of the steady performance of exacting toil.

Labor statistics for April have just become available today. They show that for that month the anthracite workers numbered 153,092. That is a decrease of 2888 men from the number employed the month before. The loss included 644 certificate-holding miners, men whose places, under the law, it is impossible to fill in less than two years. The average output of anthracite by a single miner is 165 to 170 tons per month. Of course, the miner only dislodges that much coal; he has a laborer to load it; motormen and drivers haul it; a host of men keep the mine in order and another host prepare the coal. But all these stand idle if the essential miner does not do his bit. The loss to the industry of 644 miners means therefore a loss of about 1¼ million tons per year and that at a time when the demand greatly exceeds the supply.

Since April the draft has taken several hundred mine workers, and other causes have drawn away from the anthracite industry an even larger number of men, so that the total available force in the anthracite mine workers' army today, as closely estimated, does not exceed 145,000, which compares with the 177,000 mine workers employed in the anthracite region before the war. The only way now possible to keep production up to anywhere near a maximum point is by better average working time and by increased accomplishment of the mine workers in working hours, greatly aided as these are, by the developments in machinery and mining equipment of recent years.

	Men Employed, March, 1918	Men Employed, April, 1918	Increase or Decrease
Miners	42,830	42,186	D. 644
Miner's laborers	21,990	20,768	D. 1,222
Company men (inside)	42,763	42,143	D. 620
Company men (outside)	42,949	42,515	D. 434
All other employees at collieries.	5,448	5,480	I. 32
	155,980	153,092	D. 2,888

The attention of the Secretary of War, N. D. Baker, has been called to the recruiting going on among mine workers in the Shamokin district. He promised to have it stopped. The draft will take enough men without adding to the depletion by enlistment. Provost Marshal Crowder is said to have taken the position that neither miners nor other mine workers shall be exempted or placed in the deferred class. The tonnage last month despite all the efforts of loyal mine workers and operators fell to a level 30,000 tons lower than in the same month last year, the year of the coal famine.

Reports from the Lehigh field show that the mine workers there are somewhat generally opposed to the suggested extension of the working day to nine hours, claiming that longer hours would not cause the production of any more coal. The strike at the Coal Brook colliery of the Delaware & Hudson Co., recorded at length in our issue of June 22, came to an end June 20. An order of John P. White, former president of the United Mine Workers and now a member of the United States Fuel Administration, dated June 15, was, at first, disregarded by the mine workers. A meeting was held on the evening of June 19, the men being addressed by the officers of the local and by W. H. Connell, of Scranton, the president of the Anthracite Conciliation Board. The latter pledged his word that the Board would make a careful inquiry and reach a decision as soon as possible. The vote showed 248 in favor of resumption and 114 in favor of continuing the strike. The dispute is about the placing of laborers in rooms of their own, and the alleged non-payment of the scheduled rate for the regular mining and for the removal of "shelf-rock."

On June 17 Charles P. Neil, the umpire of the conciliation board, decided in favor of the men at the Clinton colliery of the Delaware & Hudson Co., to which reference has just been made. He declared in his decision that they were entitled to an increase of 7 per cent. instead of the 3 per cent. that had been paid them under the company's interpretation of the last contract. The footmen at the Packer No. 3 colliery of the Lehigh Valley Coal Co., near Shenandoah, also received a favorable verdict, men receiving 27c. per hour being awarded 32c. by the umpire.

The principal recent feature in central Pennsylvania has been the propaganda in behalf of increased production. Successful meetings have been held at Barnesboro, Johnstown, Indiana, Kittanning, Dubois, Punxsutawney and Philipsburg, about 45,000 persons being present. The producers and mine workers of the district declare that production can be kept up to the level provided by railroad trans-

portation facilities without any necessity for lengthening the hours of labor or resorting to the conscription of working men. Pledge cards, the signers of which agree to increase their production to the limit of their power, have been freely circulated and 40,000 of them have been signed.

The foreigners in Ohio bitterly resent the action of the union in refusing work to all unnaturalized aliens and are displaying revolvers in support of their demand that they be not removed from their union affiliation. At Shadyside Belmont County, Ohio, near Bellaire, it is said that 16 revolvers were shown during a meeting of the local where a motion further supporting the expulsion of aliens was presented. At the Big Run mine of the Rail and River Coal Co. 40 or 50 Austrians and Russians hooted a man who proposed the exclusion of foreigners. At Pulteney two men who opposed the expelling of aliens presented revolvers in defense of their contention.

In the Fairmont region of West Virginia the work of unionizing continues. A single evening saw 500 members enter the union at the largest mine in West Virginia. This mine belongs to the New England Fuel and Transportation Co. The same night 245 members joined the union at Baxter, where the Monongahela Valley Traction Co. has a mine. Both these plants are on the Big-Paw-Paw Creek in Marion County. At a point remote from these, namely Masontown, Preston County, a village on Decker Creek above Morgantown, much union activity is being exhibited. Between 700 and 800 new members are joining the union.

The union in the Georges Creek region of Maryland loses its president, William Diamond, the aforetime international statistician. He had intended to go back to work in Michigan as a mine worker, but he will ply that occupation near Altoona, Penn., because of the difficulty in getting his household goods transported. Francis J. Drum has succeeded him as president of the district, No. 16, and will reside at Cumberland, the terminus of the one and only railroad which serves the Georges Creek coal mines.

"Mine the Tons That Beat the Huns"

The crowd of mine workers shown assembled in the streets of Indiana, Penn., in the illustration herewith, probably did not put their thoughts into the slogan "Mine the Tons That Make the Guns To Beat the Huns," but the idea was there and animated the meeting. It was one of a series of gatherings held throughout central Pennsylvania under the auspices of the Central Pennsylvania Coal Producers Association, for the purpose of increasing the production of coal.

John P. White, of the United States Fuel Administration, former International President of the United Mine Workers of America, was the leading speaker. Capt. Frank Schwab represented the British Army and Lieut. Robert J. Bagnes the army of heroic France. Joseph Poggiani, also of the Central Pennsylvania Coal Producers Association, spoke to his fellow countrymen in their own language. Gazy Carol addressed the Slavs in their tongue, and John Brophy, of Clearfield, president of District No. 2, pleaded with all who could understand English for a big output of gun-making coal, without which no success against the enemy of our people could possibly be secured. It is estimated that 6000 men attended the meeting.

It would be impossible to record all the rallies held in central Pennsylvania. A notable one was held the day before at Johnstown in the Cambria Theater, the presiding officer being the Hon. Francis J. O'Connor. Some of the speakers have been referred to already as being present also at Indiana. They were John P. White, Captain Schwab, Lieutenant Bagnes and Joseph Poggiani. To these were added Lieutenant Clark of the United States Army, who was in charge of an alien squad of 17 men of different nationalities, Charles O'Neil, Secretary of the Central Pennsylvania Coal Operators Association, and Father John Martvon, of Johnstown. At the back of the program was printed a pledge which every man was asked to sign. Every mine with 100 per cent. of signatures will get a National Service Flag. The pledge runs:

"I pledge allegiance to my flag and to the republic for which it stands—one nation indivisible, with liberty and justice for all. And I do sincerely believe in the proposition that coal will win the war, and therefore promise to do everything in my power to improve and increase the production of coal by every means at my command, doing so in firm belief that in this way I will contribute to the success of my country in her struggle with the Imperial Government of Germany."

The words "I pledge allegiance to my flag" are now usually written, "I pledge allegiance to the United States flag," and with this change all ambiguity is removed.

INDIANA, PENN., MINE WORKERS PROMISE THAT THEIR WORK SHALL ATTEST THEIR PATRIOTISM

Means for Increasing Hard Coal Output

"Anti-slacker" committees are to be formed at every colliery, and men who do not work steadily, or who do not aim continually to maintain a maximum tonnage, will hear from their fellows. Perhaps longer hours will be worked. The union leaders have been asked to sound the men on that proposition. No one can fail to regret the necessity for this, but after all it is by no means as grievous and unkindly a necessity as that which already takes the best young men of our nation to the field of slaughter.

And now comes a novel proposal: to reduce the consumption of coal at the mines, replacing coal, even there, by the use of wood. The Kingston Coal Co. purposes to saw wood at a mill just erected at its No. 4 colliery, at Edwardsville. To this mill waste wood of every sort will be brought. Around every mine is a lot of old timber—crosspieces, posts, ties and discarded building material. The Edwardsville mill of the Kingston Coal Co. will get busy on this waste lumber. It will be sold at cost, and it is hoped that the housewives will use it to the exclusion of wood, at least during the summer and early fall seasons, when fuel is used solely for cooking and water heating. C. F. Huber, the general manager of the Lehigh & Wilkes-Barre Coal Co., believes that a material saving of anthracite will result from the wood-burning plan, if the mine workers take to the idea patriotically.

A Patriotic Straw-Boss

The illustration herewith shows a view in the stable of the Claridge mine of the Westmoreland Coal Co., Claridge, Penn. The stableman, Robert Lisinger, painted on the brick

PAINTS BIG FLAG IN UNDERGROUND FEED ROOM

wall of the feedroom the large United States flag shown, which teaches its silent lesson of patriotism to the drivers and others having occasion to enter the stable. This stable is entirely below ground. The picture was taken by the mine foreman, Robert Ridley.

Hecla Urges Patriotism and Production

The Hecla Coal and Coke Co. in an effort to secure the coöperation of all its employees in an 100 per cent. output during the war, has inserted the following notice in all its pay envelopes, in English, Italian, Slovak, Hungarian and Russian.

"To the Employees of the Hecla Coal and Coke Co.: Over 1,000,000 Americans, including many of your friends and relatives, have given up good jobs and are now fighting in France to keep the Germans out of America. They cannot win the war without guns, ships and other supplies, in the manufacture of which coal and coke are used.

"It is your duty to support these men and to protect yourselves and your families by working every day and by producing every ton of coal and coke that you possibly can. The soldiers are working day and night at very small pay. We are asking you to work six days a week at the highest rates of pay ever earned by coal and coke workers.

"Don't be a slacker! Do your share! Don't have your friends come back crippled and blame you for failing to support them. Don't lay off and drink while they are dying for you and your families. Each day you loaf adds one day to the length of the war."

The same notice, enlarged, has also been posted on the bulletin boards at all the mines and coke plants of the company. In addition, every employee is given an opportunity to sign the "Industrial Soldier Pledge" card shown above, and each signer is given an industrial soldier's button.

HECLA COAL & COKE CO.

.....PLANT

INDUSTRIAL SOLDIER PLEDGE

Realizing that the greatest possible amount of Coal and Coke must be produced to win the war, I hereby promise to work six days a week and do my best to increase the production of Coal and Coke.

.....

PLEDGE TO FIGHT THE WAR IN THE MINE TRENCH

According to General Manager W. L. Affelder, the men are responding to an even greater extent than had been anticipated.

The enlisted or conscripted soldier works whenever there is work to do and at whatever work needs to be done. The industrial soldier whose work is in the mine works whenever there are cars and does his best to put out a record tonnage in whatever capacity he is employed. Both work for their country rather than for pay. The industrial soldier goes on working till he has made all he needs for the family, and then starts in afresh to secure the money to buy Liberty Bonds and War Savings Stamps, that he may thereby support the Government.

Labor Difficulties in Upper Lehigh Region

A correspondent, writing from the upper Lehigh region, finds the draft is affecting mostly the day hands, who, in general, are younger than the miners:

"The war has caused a most serious shortage of labor, not among the actual miners at the face, but in the men engaged in haulage and preparation. The young men who have been drafted and the fellows who are enlisting in greater numbers each day are skilled breaker hands, drivers, steam engineers and all around colliery mechanics. The men who mine coal are, in greater part, above the present draft age and, in a large percentage, are men of foreign birth. They have in many cases a boy or more already in the army. One miner in Beaver Brook has sent three boys away already and another is in the next call.

"The Beaver Brook colliery has been hard hit by the war. From the little town of about 500 people 45 employees have gone into the army. Many of the employees at the mines, knowing that there is a great shortage in labor, are taking liberties and neglecting their work. Such a nonperformance of their duties a year ago would have caused their dismissal. The young fellows below the draft age are out for the biggest possible rewards and go from one colliery to another looking for the biggest pay. In Hazleton the mines are competing with a big munition plant which has the backing of the Chamber of Commerce in its drive for employees, as if that industry was more important to the city than the mines by which the major portion of its people have for years been supported."

The Lehigh Valley Coal Co. will use school teachers in its offices during the summer vacation of the schools.

Congress Should Eliminate Long Tons

ONE of the primary Government conditions our forefathers required was that of uniform standards of weights and measures. They considered these so important that they provided for them in the Constitution. They well knew that in every country there had been a multiplicity of standards, and that this fact had made the conduct of business difficult and uncertain and had opened up the way for all manner of trickery, uncertainty and dishonesty. Fully abreast with the needs of the times, they went to much expense to secure unit standards that would agree with those in general use in the country.

To quote the Constitution, Section VIII says among other matters, that "the Congress shall have power . . . (5) to coin money, regulate the value thereof and of foreign coins and fix the standard of weights and measures." Consequently, there is no reason why Congress—or perhaps the persons deputed now to act in its name—should not establish a standard ton. There would be no opposition to such a change. Some suspicious persons might think that there was an attempt to rob the public by a shortening of the ton, but if the price were reduced accordingly, as it would and should be, there might be even a disposition to feel that an actual gain had been made by the consumer.

In the few cases in which the miner is paid by the long ton and not by measure, he might feel aggrieved by the new rate resulting from the reduced size of the ton, but the union should be ready to back up a correct readjustment with its approval and influence. In fact, the union is now so solidly on the side of a proper adjustment of matters where such an adjustment is needed that its assistance would probably be no sooner asked than given. The officials of the union are so generally behind the scenes that they know all the *dramatis personae* intimately and so can readily size up the situation.

The English ton should be as dead here as as the Imperial gallon; not that either are in themselves objectionable, but because neither can exist side by side with our weights and measures. Some day we shall have so far forgotten the long ton that we shall wonder that the English have any other, and we shall say with native simplicity: "Funny people, the English! You know I never could understand how they have 2240 lb. in their ton." The same remark has often been heard about the Imperial gallon.

It is a bad business, breaking away from British standards of weight and measure, and as much to be regretted as the fact that we are getting an entirely different technical language to that which they employ. But in this case we have no choice. We cannot change to the long ton. The short ton has shown itself preferable. We may as well hasten what is so much needed and what seems to be so inevitable.

Thus May We "Unalienate" the Alien

THE FOREIGNERS at our mines are our good friends or our sullen and indifferent neutrals, to a large extent according to the way in which they have been treated. If the alien has received the "glad hand" —that hand that America so freely extends to those it would please—then, if worthy of citizenship, he is already on his way toward a full participation in our endeavors.

The foreigner in America knows little of the United States. For the most part all he knows of the country is the *rôle* that is played by his different employers. If that *rôle* is a helpful, friendly one, the foreigner is soon inducted into our national life. Where foreign-born workmen—naturalized and unnaturalized—have unburdened themselves of their money to buy Liberty Bonds, it usually has not been because they trusted the country as a whole, a country they cannot know, but because they had faith and confidence in the managers, superintendents and foremen of the company for which they worked.

If they gave their money to the Red Cross, it was as a return for the kindness and regard they had received, the ready word of friendship and the sympathy extended to them. If they are striving now more than ever to provide coal that propels our war vessels and makes guns, ships and war material, it is because they visualize in those around them, especially in those employing them, those with whom they are daily working, a people worthy of comradeship, a people they desire to see succeed in all their endeavors.

The people who complain most about the foreigner's lack of Americanism are those who sin most against him, who treat him with studied contempt. Fortunately they are few. Ignore the barrier between native born and foreigner and the barrier will fall. It is even now falling.

Wonderful indeed are the foreign-born in America. Centuries of propinquity, ages of propaganda, persecution and purchase all have failed in parts of Europe to make a homogeneous people. Here the work is done in a generation, in less than a generation, almost without any effort. The foreigner is perhaps not entirely made over. His enunciation, his strange groupings of words, his peculiarities of deportment still remain to interest us, but he becomes an American in his preferences and an American in his willingness to make sacrifices and give service.

Even the American Germans have only been about a half of one per cent. disloyal. The Liberty Loan sales have perhaps been larger among them than among our own people, for they have a thrift to which our people are strangers. Our generosity to them has, in but few cases, been a mistake. The American German has, in most cases, responded to our good will.

A stranger comes to your home from California, let

us say, and you gather round him. His differences please and interest you, and you delight to show courtesies to this visitor from a distant state. How your courtesy to him puts his own kindliness of heart in action! What a wonderful host are you and what a gentle guest is he! It will not be otherwise if we treat with kindness those of another tongue, another country and perhaps another creed. Their very "otherness" is a bond of union of great worth to those who thus recognize it. It gives them a chance to show again the things that they most prize and which they know the stranger will enjoy with them.

Look Around for a Speaker

UNFORTUNATE indeed just now is the mining village where, for lack of an adequate speaker, the war and all that it means has not come home vividly to everyone, especially every English-speaking mine worker. It is necessary that someone should be found at every plant who can declare how intimate is the relation between guns and coal, and do it so clearly that the man who labors at mining cannot fail to realize the matter. Someone is needed who will show how the mine worker contributes to the waging of the war.

The man who makes luxury goods may work negligently if he pleases. His product may be inferior in quality or quantity; the war will be finished just as soon. But the man who mines coal mines it to back up the Army and Navy. He must not falter or fail. Whatever the work others may be doing, his work is one which directly contributes to victory. Happy indeed should he be that he finds himself where he can render his country such a great service. The man in a luxury trade uses excellent raw material for a useless purpose. He destroys the labor of others, adding to it other labor, only to waste that also.

But the man who mines coal is doing useful work. His is the work of honor at this time. Every little mining town should have a forceful orator who will proclaim this fact, so that it will not be a single moment overlooked.

Some will speak lightly of his story, for there never was a story yet, however true it might be, that did not find its derider; never a bulletin or picture that some one did not find fault with it. But there are always some who will accept the story, bulletin or picture on its full face value; some who will accept at least a part of it and perhaps none who fail to retain some fragment of the thought expressed.

Where there are unions the work of speeding production may well be done through them. The union leaders have long ago seen that the mine worker is the backer of both Army and Navy in the present war. The mine worker's son and brother in uniform are required to give untiringly of their efforts, and he himself can give no less; for his work is necessary for the support of these men at the front and will in large measure reduce the loss in life and shorten the duration of the battle.

We say again, "Look around for the speaker." If you can, get him from the ranks, get a man who can speak as brother to brother. Every mine village should have its spieler to give purpose to its efforts and to bear the message of the Nation to the mine worker.

Do All Your Employees Really Know?

TOO often the officials of a company who have been reading diligently about the war in every spare moment assume that all the employees have been doing the same, and they feel it a waste of time to repeat to the mine workers what might seem obvious truths; but just lately several cases have occurred that show that there are a number of people with wholly erroneous ideas, implanted doubtless by persons having an active alien or private interest to advance.

In Hoboken, N. J., a manufacturer induced a number of his employees to buy War Savings Stamps. Probably he laid all the stress on the patriotic duty of buying them, which, of course, is an excellent form of argument for their purchase. As a result of this appeal and the pressure of fellow subscribers, they agreed to buy stamps. The propagandist or profiteer then came along with the story that the stamps were of no value, and one particularly vicious person went around buying them at a considerable margin below their cost to sell them in New York City. It took only a word to make the women, who were parting with these stamps so readily, decide henceforth to keep them. They were easily brought in line by a suggestion from someone they did not know. A difficulty, so easily removed, should never have been allowed to make any headway.

Another example: A long line of people at a dime saving bank were talking about Liberty Bonds. One man in the row declared that he would much like to buy the bonds, but he needed the interest, and he could not afford to withdraw his time deposit from the bank where he got his percentage regularly. Another even wanted to know how often he would have to pay interest on his bond after he had bought it.

Perhaps there are no men around the mines, native or foreign, who are quite as ill-instructed as these men and women, but there may be other difficulties that keep them from doing their duty, and every mine official should make it his business to learn the nature of these problems and should study how he may correct them. It does not do to take knowledge of anything for granted in these days of propaganda, especially in sections where many people cannot speak the English language.

After all, banking and investment are not easy things for a man to understand. It takes time to learn how to avail oneself of the Government's offers. The language of banking in which many of the notices are couched is more exact than clear. Where the work of acquainting men with the Government offerings has been well explained, the people are eager to buy and ready to retain the securities and stamps almost indefinitely. No one holds so tenaciously to the purchased bond as does the small bondholder. What he buys he keeps until a rainy day. He is not an uneasy speculator but a satisfied investor.

The people will be more likely to feel aggrieved at the insistence of the Government on the paying off of the bonds when they fall due than upon any of the other provisions. We wager that the man who has received 4½ per cent. from the Government for many years without a hitch will feel quite grievously dispossessed should he, when the bond expires, have to accept payment and put the money in the bank at 4 per cent. or less.

The Army Behind the Lines

Uncle Sam might have drafted any one of us. Because he did not do so is a good reason why we should do our whole duty in the industrial army and all in step march ahead whenever Uncle Sam cries—"Forward! March! A little more pep, please. This is no route-step or go-as-you-please."

DISCUSSION BY READERS

The Mining Situation

Letter No. 1—While statistics show that the production of coal in our mines has greatly increased, it is still far below the present demand, and the question is constantly asked, "What is it possible to do to increase the production?" Public meetings have been called to discuss the question; large coal companies have held conferences with their officials; and both the Government and mining companies are giving every encouragement to miners to induce them to increase their efforts to mine coal.

At a recent meeting of the superintendents of a large coal company, the general manager, in the course of his remarks, stated that because of labor and other conditions, the company had contracted to supply considerably less coal than last year and, notwithstanding this fact, they were much behind on their contracts.

The seriousness of the coal situation is not realized by the general public. Several causes are responsible for the condition. The draft has called many men from the mines and others have left to seek work where they are offered higher pay; but, aside from all this, the miners themselves are not working as they should. The truth is, the miners are making big money and, as a rule, have an overpowering desire to spend what they make, some in drink, some in pleasure and luxury, but comparatively few in investments in Government bonds and war-savings stamps.

Instances are numerous that show the restive disposition of many miners who are making good money, but who yet are dissatisfied. One of my men who drew $70 for two weeks' pay came to me with the claim that he was "not making enough money." He named a man in an adjoining town who drew $96 for only eight day's work. Had the man worked the 13 days of that pay he would have had $156 in his envelope; but he laid idle the remaining five days, or over a third of his time, which is no exceptional case.

Pleasure vs. Work

While a year or two ago autos were owned only by the higher mine officials, today it is hardly an exaggeration to say that nine out of ten autos seen speeding from one mining town to another are owned and driven by foreign-speaking miners. Now, while no one would begrudge their amusement and pleasure, the fact is that the habit of a good proportion of our miners to visit their friends in adjoining towns is responsible for the loss to the country of a third of the possible production or capacity of the mines.

Few miners realize what this means to our country in the present crisis. Ninety per cent. of these men are foreign born; many of them cannot read and all they know is what they hear. The suggestion has been made that wounded soldiers who can speak their language be sent among them to inform them of the real conditions and the great need that they should work their full time in the mines. While this would do some good, my opinion is that it would not accomplish the desired result.

The Soldier and the Miner

The question to be decided is, What is the cure for these conditions? In attempting to answer this question, it is well to remember that the Government makes the service of the boys drafted for the army compulsory. They are obliged to do every class of work required to make them hardened soldiers, and are paid $30 a month for their services, and many of them have left good positions that afforded them four or five times that amount.

If a drafted man grumbles, he is called a "slacker." But, the great army of workers at home are paid increased wages and permitted to work where they please and as they please, although their services are as essential to the success of the war as that of the fighters at the front.

Let me suggest, in closing, that the seriousness of the present situation demands that the Government should take more drastic means to keep the miner at work. If it is asked "How can this be done?" my answer is, place a Government inspector in each mining district who will act in the capacity of a truant officer. Given a list of the men absent from a mine without excuse from the foreman, the inspector would investigate at once, ascertain the circumstances and impose such a fine as may seem fit. It will do no good to send the man to prison, but a fine would send him back to the mine and make him less willing to absent himself for pleasure or other needless cause.

McIntyre, Penn. THOMAS HOGARTH.

Private Business and the War

Letter No. 1—At the present time, we hear much talk of the need of private business giving way to the Nation's interests, for the winning of the war. I was pleased with the timely verses of Berton Braley, which appeared as a Foreword in *Coal Age*, May 18, and were designed to teach the lesson of one's private interests being subserved to the necessities of the great struggle in which we are engaged.

It strikes me that this is a lesson that every miner must learn as well as men who are conducting public affairs and interests of various kinds. In every case the business of the individual must be regarded as second to his duty as a citizen and one of a great army of industrial workers.

Only recently I have been led to apply this reasoning to the case of the skilled and unskilled miners who work side by side in our mines. Take, for example, a machine mine where safety requires that the most skilled miners should be employed on pillar work and in other danger-

ous places where their work will not permit them to earn the same amount that they could if employed in easier tasks.

On the other hand, the unskilled laborer is frequently put to work on loading coal where he is practically safe and free from injury. It has happened that, in the performance of this work, he is enabled to earn comparatively larger wages than his skill and acquaintance with mining work would warrant. As a result, the skilled miner is apt to feel that there is an unjust discrimination in the choice of work, although he recognizes that it would not be right to place the unskilled man where he would be liable to injury because of his inexperience in the mine.

The mine foreman recognizes the appeal made to him and replies, "Yes, James, I am going to give you a machine-cut right handy to the stump you took out yesterday, and you and that new man whom I will send with you can load it out. When that is done you can both start mining the remainder of the stump; but you will have to watch your man and see that posts are set to keep him safe."

Suppose, now, the miner should reply that it was not his business to look after the other fellow; he must learn to do that himself. How would such a reply be regarded if made by a soldier at the front who refused to look after the safety of a comrade. He would be sent at once to the rear and be court-martialed for his disloyal attitude.

Permit me to ask, In fairness to his fellow miners and loyalty to the cause, should not every miner preserve the same attitude toward his fellow worker as is demanded of the soldier toward his comrades? Are they not all working under the same banner, and does not the same responsibility rest on the miner as on the soldier at the front? R. W. LIGHTBURN.

Perryopolis, Penn.

Shortage of Mine Labor

Letter No. 1—An item that appeared recently in *Coal Age*, May 25, p. 986, drew attention to the protest made by mine operators against the draft being made on competent and experienced miners who are daily being taken from their work in the mines and sent to war-training camps.

A short time ago a committee of coal operators made a special trip to Harrisburg for the purpose of conferring with Major Murdock. They explained to him that the draft for the army was reducing the employees in and around the coal mines to an extent that threatened to greatly interfere with the production of coal in the anthracite district. They urged that competent experienced miners employed underground should be exempted from military duty and claimed that the coal industry was being hit harder than any other necessary industry.

To the unprejudiced mind, there would appear to be some camouflage in the action taken by these operators. If it is a fact that coal companies are being crippled by the shortage of labor growing out of the necessities of war, as this committee claimed, it would seem that they should be compelled to show figures giving a correct account of how many men they have lost through the draft and how many men have left the mine to seek other work where they could get more wages. It is my belief that such figures would show that the shipyards and railroads in the country have taken more men from the mine than have been called by the draft.

In districts Nos. 1, 2 and 3, in the city of Wilkes-Barre, the records show the following number of men drafted from different coal companies in that vicinity: Lehigh & Wilkes-Barre Coal Co., 17; Lehigh Valley Coal Co., 3; Pennsylvania Coal Co., 1; and the Delaware & Hudson Co., 3, making a total of 25 men who will leave these mines, on June 24, for training camps.

It would naturally be supposed that coal companies, fearing the loss of their more experienced and competent men, would submit a list of such men and claim for them industrial exemption from the draft. On the other hand, there are numerous instances where discrimination has been shown to favorites, and where sons of bosses have received special mention. I am proud to say, here, that the feeling of loyalty to one's country has triumphed over these efforts, which have, in most cases, been spurned by the boys themselves.

Efforts of Companies To Have Men Exempted

In one instance, a large coal company left no stone unturned to have a certain young man exempted, who stated, when the report reached him, that he was "no slacker" and promptly enlisted. It is not surprising that a large number of the younger men working in the mine have recently been aroused by the situation. These let it be known, yesterday, that they would take their regular place in the draft, regardless of their work in the mine. The probability is that they were forced to take this action because men for whom exemption had been asked had been commonly termed "slackers" by their comrades.

Let me suggest that coal companies face a peculiar situation. From my observation, the shortage of men in the mines is due largely to the inducements of the larger pay offered for work in other industries. To overcome this effectively and hold their men it would be necessary for coal companies to increase wages correspondingly; but this cannot be done without increasing the cost of production of coal.

Disproportion in Pay for Mine Work

An instance came to my knowledge, a few days since, of a young man who had been employed running an air compressor, two turbines, and an electric dynamo, all housed under the same roof. He served a 12-hr. shift for a measly $3.50 a day. The man was a good engineer, but he had no regrets when giving up his job at the call of the draft. There is little wonder that the place is still vacant, and no one appears to be anxious to assume the responsibility at the small pay offered.

Comparison shows that the miner is the poorest paid workman in any industry, at the present time, and yet the product of his labor underlies production in practically all of the industries. Today, any able-bodied man can earn $3.50 for common labor, in other work than mining, and it is not strange that they are leaving the mines to seek such work.

I want to say, in closing, that the claim for exemption from draft cannot be urged with any more reason

for the miner than for the farmer, or men working on Government work in the shops and the shipyards. If these classes of workers are to be exempted, then, who will be left to do the fighting? Were miners to be exempted by a ruling of the War Department, there would be a host of men seeking employment in the mines who are not competent for that work.

Wilkes-Barre, Penn. JUSTICE.

Letter No. 2—The frequent references both in *Coal Age* and the daily papers, regarding the shortage of labor throughout the anthracite district, leads one to believe that there will inevitably result a big shortage of anthracite next winter.

The reasons for men leaving the mines in such large numbers are numerous. Some are called away by the draft, many are seeking jobs in other industries or volunteering for service in the army and other causes besides are depleting the ranks of the mine workers. Several hundred men have already left the Wyoming Valley and the same is true throughout the region.

Considerable alarm is felt among anthracite operators regarding the effect of the recent draft call, which requires Pennsylvania to furnish 3750 men for the army. Both the operators and the United Mine Workers organization are attempting to estimate what proportion of this number of men will be taken from the mines. If the present call affects the miners to the same degree as did the last call it is generally conceded that many of the mines will be forced to close down.

WHAT DRAFT OF MINERS MEANS TO THE MINES

Every miner taken away for military duty means the training of a new man to take his place, and the Anthracite Mine Law requires that a man work underground, in the mines of Pennsylvania, for two years before he can secure a certificate permitting him to mine coal or work as a miner. It is quite evident, therefore, that every experienced miner called by the draft will curtail the production of coal, which is already restricted by the lack of men.

With the hope of relieving the labor-shortage situation, a committee of four, composed of members of the Luzerne County Exemption Board, was appointed to go to Washington, in company with a committee of mine operators, to confer with the proper authorities in an effort to obtain a ruling that would exempt coal miners and skilled mine laborers from military service. I understand that similar committees have been selected from other mining counties, for the same purpose.

The problem, however, has another aspect that is equally serious. Most young mine workers balk at these exemption plans. Unwilling to assume the role of "slackers," many of them have been aroused by the deferred classifications, which have been accorded some of their number in a wholesale manner by district exemption boards. It is feared that they may take the stand of refusing to accept such deferred classifiation arising from the nature of their work in the mines. An official of the United Mine Workers organization is authority for this statement.

While it is true that this stand of young workers reveals a super kind of patriotism, there is another phase of the situation. A growing feeling of discontent, because of what is termed "unjust discrimination," results from men being moved forward on the draft list by reason of the wholesale exemptions secured by the coal companies for favorites in their employ.

In the opinion of some operators, the situation demands a change in the anthracite mine law, which requires two years of labor underground, in the mines of Pennsylvania, before a man can receive a miner's certificate. Many operators say that six months is sufficient to give a man the required training for the work of mining coal. Personally, I believe this would be a grave mistake and is not required by reason of the scarcity of miners in the anthracite field.

Kingston, Penn. FRED B. HICKS.

Detecting Marsh Gas by Smell

Letter No. 1—Reading the inquiry in regard to carbon monoxide being a "supporter of combustion," *Coal Age*, June 15, p. 1128, shows that one cannot rely wholly on what the textbooks say. In the minds of many, there is some question in regard to marsh gas having no smell.

Methane or marsh gas is described as a "colorless, odorless and tasteless gas"; yet many men declare that they can smell it. In the hope of clearing up this point and throwing some light on the subject, allow me to submit the following:

When going my rounds as an examiner I have frequently suspected the presence of gas and rarely failed afterwards to find it in sufficient quantities to give a flame cap in the lamp. Perhaps, however, the perception was not wholly by smell, though mainly so as I believe.

An Alberta mine inspector tells me he has often had the same experience. Once, while I was accompanied by another examiner, we entered a room and he exclaimed, "There is gas in here, I can smell it." We found no gas, however, and as we came out he said, "I guess it was the timber I smelled."

I am inclined to think it was the timber, in that case. All the timber used around here is conifers from the eastern slope of the Rocky Mountains. It is highly resinous and gives off a pleasing odor for several months after it is cut. It is usually where the odor of the timber is noticeable that I have suspected gas. As a rule the odor of the timber is stronger where much gas is present. It is only when the timber is old and has lost its odor that the presence of the gas makes no difference.

My explanation is that the methane acts as a solvent upon the more volatile portion of the resins of the timber and renders them more active, in much the same manner that kerosene acts upon pitch. It may intensify whatever action the odor has on the sense of smell.

Coalhurst, Alta., Canada. T. EDWIN SMITH.

First Aid to the Uninjured

Letter No. 7—The writers on this subject have drawn attention to a most important feature of the safety-first movement. More than anything else in coal mining is the necessity of aiding men to recognize the dangers with which they are surrounded and take precautions to avoid possible accidents. This aid must be given

to the man before he is injured. What most of us need, however, is a good supply of common horse sense.

When a man has been injured seriously, perhaps through carelessness of his own, or when a man has been arrested for a violation of mining law, he is in a position to appreciate more fully the foreman's solicitation on his behalf. But, it is important to bring men to the same state of appreciation before their neglect has resulted in serious injury to themselves and perhaps to others. It may be necessary to punish a man for carelessness, in order to bring him to appreciate means taken for his safety.

Chances Taken by the Average Miner

Nobody will deliberately pull a ton of rock or coal down upon himself; but scores of miners will continue to load a car, under a roof that they know is not safe, intending to secure the loose top as quickly as they have loaded out the coal beneath it. Men take these chances continually, and it is for the foreman to use radical means, if necessary, to cure them of the habit. No man should take chances on his life and health.

Many mine foremen are bewildered at the prospect of impressing on their men the need of taking greater care in their work and many hesitate to enforce strictly the safety rules of the mine. The task will be made easier if such men will classify the accidents that commonly happen in mines, owing to men's neglect and carelessness. It will enable them to apply the right remedy in each case, and better results will follow.

Cause of Greatest Number of Accidents

By far the greatest number of accidents in mines occur through falls of rock or coal at the working face. Nine out of ten of the accidents of this class can be avoided by the exercise of due care and caution on the part of the miner and a close supervision of his work by the mine foreman and his assistants. Because the miner is prone to ignore the laws and safety rules made for his own protection is no excuse for a mine officials' laxity in enforcing them.

Let every mine foreman place accidents of this kind in a class by themselves and study the best means to avoid them. He will soon discover that a large portion of the responsibility rests upon himself. He will find it necessary to enforce a rigid discipline in respect to the timbering of working places, and to supply and keep on hand in each place a sufficient amount of timber of the right size and kind. He will see that these provisions must be accompanied with a close supervision of each miner's place and work. He will permit no one to load a car before he has secured roof reported as unsafe. Dangerous rock on haulage roads and travelingways must have an equal share of the mine foreman's attention.

Accidents Due to Blasting

A second class of accidents embraces those due to the blasting of coal and rock. There is less excuse for accidents from this cause than those in timbering. No unseen hand threatens the miner in preparing a blast, as in loading a car under a roof judged to be solid and safe when, in reality, a hidden slip or a "pot" formation renders it insecure. There are but few legitimate excuses for accidents due to blasting coal. Nearly every box of powder contains printed instructions regarding the safe handling of the explosive and the precautions that must be taken in its use.

The accidents from blasting are not so many, however, and usually arise from careless practices, such as using a short fuse, crimping a cap with one's teeth, smoking a pipe or cigarette, or approaching a light too close to the powder when preparing a charge. A miner will sometimes be found riding a motor trip with explosives on his person; he may carelessly carry a few caps with his powder; or he may allow the explosive in his charge to come in contact with a live wire and, in many other ways, do things that he knows he should avoid.

Accidents from the Movement of Cars

I will refer to one more class of accidents, namely, accidents due to the movement of cars. These are largely the result of bad management in the mine, or disobedience to rules by the miner. Where mechanical haulage is performed, men should not be permitted to travel the haulage roads, but a separate travelingway should be provided whenever practicable. Refuge holes should be cut in the ribs and a suitable clearance at the side of the track be maintained wherever it is necessary for men to travel a haulage road.

Strict rules should be enforced in regard to men riding motor trips and violations of such rules should be suitably punished. All tracks should be maintained in good condition and protection should be afforded against live wires, wherever men or animals may come in contact with the same. If sufficient attention is given to these and other provisions for the safety of men, there will be a noticeable decline in the number of accidents occurring in the mine.

Thomas, W. Va. W. H. Noone.

Strong vs. Weak Stoppings

Letter No. 2—Previous to the mine enactment of 1893, in Pennsylvania, there were many extensive mines in which the stoppings were built of wood. Sometimes these were of the most flimsy character, the material used being often procured from old store boxes. Fortunately, no great explosions occurred which would, undoubtedly, have blown out every stopping on the entry, from the face to the shaft bottom, and made the work of rescue very slow and tedious, because of the necessity of rebuilding all the stoppings.

Such flimsy stoppings may be rightly described as being very flexible. At times, a heavy shot would move them so that they required to be repaired before rescue work could proceed. Indeed, stoppings of that kind were short-lived and had to be constantly renewed. In my opinion, any form of light stopping that is easily blown out is dangerous, and the same is true of a collapsible stopping. A light stopping soon begins to leak air and makes it impossible to conduct the air current, in sufficient quantity, forward to the working face.

The suggestion made by E. P. Brennan, in his letter, *Coal Age*, June 8, p. 1077, that a modified system of mining be used so as to form an explosion barrier at the mouth of each pair of cross-entries could only be employed in the laying out of a new mine. It

has made me think, however, that some systems of mining are more favorable to the development of an explosion than others. I am inclined to believe that the longwall system advancing has the cleanest record in this respect. In that system, there are practically no stoppings other than the packwalls.

My experience has taught me that the best form of mine stopping is one consisting of a good solid packwall faced with 18 in. of brick on each side. The brick should be laid in cement. This form of stopping should be built on all main and cross-headings. A 50-ft. pillar should have a 12-ft. packwall for a stopping, and all stoppings should be set into the ribs a depth of 12 in. The pack should be well rammed as it is brought up to the roof so as to form an air-tight joint at the roof.

My preference is for explosion-proof stoppings, in any system of mining. I believe that, while such stoppings will not prevent the occurrence of explosions, they will greatly expedite the work of rescue, which would then only be delayed by the entries being blocked by possible roof falls. In a mine with strong stoppings, it seems to me that there would be less wrecking of the passageways, as the explosive blast would have a straight course and quickly spend itself.

Perryopolis, Penn. LUMEN.

Letter No. 3—A common mining practice has been to use two kinds of stoppings, designated as temporary and permanent. The temporary stoppings are usually built by using 1-in. boards, slabs or refuse lumber of some sort daubed with clay or cement to prevent leakage of air. This form of stopping is simple and may be built by any one understanding the use of saw, hatchet and nails. When built of rough boards of single thickness it will stop about 50 to 75 per cent. of the air traveling from passing immediately back into the returns. The permanent stopping is a more elaborate affair and has, no doubt, received much more attention in the selection of materials and methods of construction. The state law makes it compulsory to build the permanent stopping of incombustible material and of ample strength. No stipulations are made concerning the thickness.

In a mine entirely free from combustible gas, having no large accumulations of fine coal dust, any available material such as top rock or slate will make a satisfactory stopping if the work is done in a skillful manner. When a mine is gaseous, with coal-cutting machinery producing large quantities of finely divided coal dust, the permanent stopping becomes a matter for careful consideration. Before deciding on the kind of materials most suitable for the work, it will be well to understand the double purpose of a mine stopping.

First, it must be air-tight to insure the complete distribution of the entire ventilating current. Second, it should afford quick release when the mine resistance or pressure—due to accident—is above normal and to provide a short circuit for air and rescue work in the event of a serious disaster.

The stopping built of slate or rock, having double walls with a pack of dirt, clay or other material between them, is much in favor with a large majority of mine officials. When this is made thick and strong, it is said to be proof against shock arising from an explosion. The explosion-proof stopping is the outcome of an idea advanced by certain authorities in support of their belief that its indestructibility tends to throttle the explosion in its incipiency, by increasing the mine resistance. In support of this idea one writer says: "It has been found that old mines, where the mine resistance is great, are practically immune from dust explosions; they occur most frequently in new mines where the mine resistance is comparatively small."

Resistance to Development of an Explosion

In this instance there seems to be some confusion with regard to the term "mine resistance" in its relation to an explosion. What is commonly known as frictional resistance or total ventilating pressure is of small moment in accelerating or retarding the development of an explosive wave. What does count is the difference in resistance between a narrow working place with four solid walls, including indestructible stoppings, and another place where the stoppings are arranged to afford a quick release of high resistance brought about by abnormal conditions. It will be found that where old mines are free from explosions the condition of the ventilation is the most potent factor.

The writer referred to, in a further effort to strengthen his claim, says: "It is well known that the easy removal of insufficient tamping increases the danger from a blownout shot, and an increase in the length of the hole and a corresponding increase in the length of the tamping reduces the danger." This is very true. Now let us assume that we withdraw the tamping—affording a complete release of all resistance—then what will happen? There will be flame and smoke unaccompanied by an explosion.

Again, assume that we stem and tamp the hole solidly, its entire length, using the same amount of explosive and making the resistance complete and effective; what will be the result? A rending, smashing, shattering explosion of full destructive strength and power will be developed. The indestructible stopping would be the ideal of perfection if we could be absolutely certain of the future conduct of a mine.

Mine Stoppings in the Future

It is a safe prediction to make that the mine manager in the future will arrange his stoppings for ventilation on a much different plan from that of the present or past. Permanent stoppings will be constructed with a view to their flexibility and thickness. All stoppings within 300 ft. of the working faces will probably be built in keeping with the advancement made in the science of mining.

These temporary stoppings will be a portable arrangement, set in a frame after the fashion of a trapdoor, and held firmly in position by springs adjusted to withstand the normal resistance of the mine and made to release or collapse when the resistance becomes abnormal. The quick release of all resistance will effectually prevent the development and continuity of an explosive wave, if applied near the point of origin.

Much can be accomplished that is thought to be impossible in respect to the prevention of mine explosions, and I shall be glad to learn the views of others.

Confluence, Penn. H. E. GRAY.

INQUIRIES OF GENERAL INTEREST

Designing a Mine Siphon

Kindly explain what conditions are required for the successful operation of a siphon in a mine; or, in other words, what elements enter into the design of a mine siphon. INSIDE FOREMAN.

Pittston, Penn.

The essential requirements for the successful operation of a mine siphon are the following:

1. The pipe line must run full; that is to say, the size (diameter) of the pipe must be such that it will conduct the required flow of water, under a velocity determined by the effective head and the frictional resistance of the pipe. This is necessary in order that the water flowing through the pipe shall sweep away any air that might otherwise separate from the water and accumulate at the crown of the siphon.

2. In order that the siphon shall run full continuously, the diameter, length and effective head must bear a fixed relation, in both branches of the pipe. For example, the ratio of the fifth power of the diameter, in inches, to the length of the pipe, in feet, multiplied by the effective head, in feet, must be the same for both the intake and discharge ends of the siphon. The *effective head* at the intake is the atmospheric pressure minus the vertical lift from the level of the water in the supply basin to the crown of the siphon. The *effective head* in the discharge end is equal to the vertical height of the crown of the siphon above the point of discharge minus the atmospheric pressure.

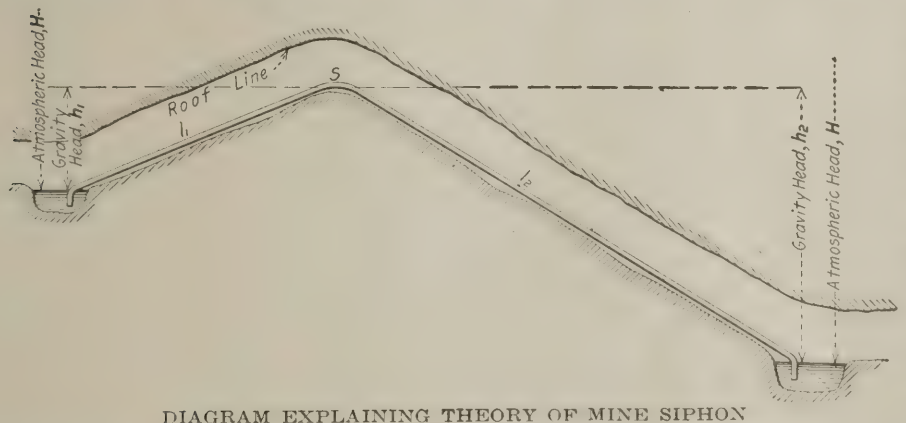

DIAGRAM EXPLAINING THEORY OF MINE SIPHON

3. There must be no leaky joints in the pipe, and all unnecessary obstructions, in the form of sharp bends in the pipe, valves, and other hindrances must be avoided as far as practicable. The mouth of the pipe must be kept sufficiently submerged beneath the surface of the water in the supply basin to permit no air to enter the pipe at that end.

A siphon that fulfills these requirements will run continuously. In order to start the siphon, it is necessary to fill the two branches of the pipe through an opening at the crown, which must then be tightly closed by a good valve. During the filling of the pipe, both the intake and discharge ends must be tightly plugged or suitable gate valves must be provided at these points and closed until the pipe is full. Sometimes a small pump is used to fill the siphon instead of pouring the water into the pipe at the crown.

When a siphon line is not properly proportioned, as here explained, it will empty itself in a short time or the accumulation of air at the crown will prevent its operation. To avoid the first of these conditions it is common to use throttling valves to control the flow of the water at the discharge end, and to escape the second condition an air trap must be provided at the crown, through which the accumulated air can be withdrawn from time to time as necessary.

Referring to the accompanying figure and calling the atmospheric head, H, expressed in feet of water column, the gravity head, in feet, length of pipe, in feet, diameter, in inches, on the intake end, h_1, l_1, d_1; and, on the discharge end, h_2, l_2, d_2, respectively; the effective intake head is $H-h_1$, and the effective discharge head h_2-H. The relation of these elements, as stated in the foregoing rule is then expressed by the formulas

$$(H - h_1)\frac{d_1^5}{l_1} = (h_2 - H)\frac{d_2^5}{l_2}; \text{ and } d_1 = d_2\sqrt[5]{\frac{(h_2 - H)l_1}{(H - h_1)l_2}}$$

These formulas are practical and should always be used to determine the sizes of pipe best adapted to different conditions regarding the length and vertical lift, or rise and fall, in each branch of the siphon. Also, it is well to remember that the atmospheric head H will depend on the depth of the mine and the system of ventilation employed. In practice, a good aneroid should be first compared with a standard mercurial barometer on the surface, and then taken into the mine where the increase in the reading is noted. The increase, if any, is added to the reading of the barometer on the surface and the result multiplied by 13.6, the specific gravity of mercury, and divided by 12 to reduce inches to feet, will give the atmospheric head H, expressed in feet of water column.

Straightening Brittle Rails

Kindly explain how brittle iron rails can be straightened without first heating them, as claimed by a correspondent, *Coal Age*, May 4, p. 847, without breaking the rails or taking them out of the mine. DOUBTFUL.

Scranton, Penn.

We understood that our correspondent would tell us his method later and hope that he will do so soon. We have never heard of brittle iron rails being straightened without first being annealed by applying heat.

EXAMINATION QUESTIONS

British Columbia Examination, First Class. May 14, 1918

(Selected Questions)

Ques.—How many cubic feet of marsh gas will be required to be generated in a mine each minute to render dangerous a current of 30,000 cu.ft. of air per minute?

Ans.—The percentage of marsh gas required to render mine air dangerous will depend on the character of the coal mined and the method of working. In the mining of a soft, inflammable bituminous coal, especially with machines, the danger point may be reached when somewhat less than 1 per cent. of gas is present in the air. Much will depend on the inflammability of the coal and its suspension in the air.

On the other hand, in the mining of a harder and less inflammable coal, 2 per cent. of gas in the air may mark the danger line. In the mining of anthracite, 2½ per cent. of gas will generally indicate the approach to danger. Taking 1 per cent. of gas in the return current as indicating the danger line, the air will form 100 — 1 = 99 per cent., and the total volume of the return current is then 30,000 ÷ 0.99 = 30,303 cu.ft. The volume of gas that must be generated to produce this condition is therefore 30,303 — 30,000 = 303 cu.ft. of gas per minute.

When 2 per cent. of gas marks the danger line, the total volume of the return current is 30,000 ÷ 0.98 = 30,610 cu.ft., and the volume of gas generated, in that case, is 30,610 — 30,000 = 610 cu.ft. per minute.

Ques.—Explain the law of diffusion of gases and its effect on their behavior in mines. Give rule and example showing how to find the comparative velocity of diffusion of the different gases.

Ans.—The law of diffusion states that gases of different density diffuse into each other in the inverse ratio of the square roots of their densities. The effect of diffusion is to cause a rapid and intimate mixture of the gases in contact with each other, and the density of the mixture will depend on the proportions and densities of the two gases.

The relative velocity of diffusion of a gas into air is equal to the reciprocal of the square root of its density referred to air. For example, the relative velocity of diffusion of marsh gas into air is $1 \div \sqrt{0.559} = 1.337$. The relative velocity of diffusion of carbon dioxide into air is $1 \div \sqrt{1.529} = 0.808$. In each case, the relative velocity of the diffusion of air into the gas is 1 or unity.

Ques.—What effect has a blownout, windy or a tight shot in the presence of firedamp?

Ans.—In the explosion of any of these shots, more or less flame is produced and projected into the surrounding air at a high temperature. If firedamp is present, it will be ignited by the projected flame and a gas explosion will follow, which may or may not be propagated throughout the mine, depending on the gaseous and dusty condition of the mine air.

Ques.—If a volume of 1200 cu.ft. of marsh gas is mixed with pure air in such proportion that when exploded all the carbon in the marsh gas combines with the oxygen in the air what volume of carbon dioxide will result, measured at the same pressure and temperature?

Ans.—In the complete combustion of marsh gas (CH_4) where all of the carbon of the marsh gas unites with the oxygen of the air to form carbon dioxide, the volume of the latter gas produced is equal to that of the marsh gas burned. In this case, there will be produced 1200 cu.ft. of carbon dioxide, measured at the same pressure and temperature.

Ques.—How would you remove firedamp from a section of a mine, after an explosion? What dangers would you expect to meet and how would you overcome them?

Ans.—Much will depend on the conditions existing in the mine and the arrangement of the workings; but, in general, it may be stated that only experienced miners must be employed in the work, and these must be equipped with safety lamps of an approved type and in good condition. No advance must be made ahead of the air current, which must be conducted forward by repairing stoppings that have been injured and erecting lines of brattice where this is necessary to carry the air forward. When the brattice is extended, sufficient time must be given for the current to sweep away the gas and make further advance possible and safe.

When entering a mine after an explosion there is danger of men being overcome with the afterdamp of the explosion. There is also danger of igniting a fresh body of firedamp that may have accumulated since the explosion occurred. To avoid being overcome in the afterdamp, exploring parties should advance slowly and with caution, making frequent tests to ascertain the condition of the air. Caged mice or birds should be carried and closely watched to observe any symptoms that would indicate the presence of poisonous gas. These little animals are prostrated much more quickly than persons and their presence is a safeguard against the presence of carbon monoxide which will not be indicated on the flame of the safety lamp. No advance must be made ahead of the air without the use of breathing apparatus.

Ques.—Find the weight of 1 cu.ft. of marsh gas, at a temperature of 70 deg. F., when the barometer is 29.5 in.

Ans.—The weight of 1 cu.ft. of air at the given temperature and barometer is

$$w = \frac{1.3273 \times 29.5}{460 + 70} = 0.07387 \text{ lb.}$$

Its specific gravity being 0.559, the weight of a cubic foot of marsh gas is $0.559 \times 0.07387 = 0.0413$ lb.

COAL AND COKE NEWS

Harrisburg, Penn.

Prominent coal operators declare that they will appeal from Provost Marshal Crowder's refusal to grant deferred classification to men employed in and about the mines, and that if necessary they will carry it up to President Wilson. Pointing out that the tonnage of anthracite mines decreased over 100,000 tons last month over the same month last year, they say that unless some action is taken at once that each month will show a greater decrease and that the country will face a greater fuel shortage next winter than it experienced last year. The draft increments of June 24 and 27 will take about 5000 men away from the mines, and as the working force is 32,000 short at present, they point out that the situation at present is extremely critical.

Thousands of dollars in compensation will be received by dependents of mine workers killed at work on company property as a result of a final decision by the Supreme Court in the compensation case brought by Mrs. Julia Gurski, of Nanticoke, against the Susquehanna Collieries Co. in which the Supreme Court upholds the award of the Referee. The decision is one of the most important to mine workers that has resulted since the passage of the Workmen's Compensation Act.

Charleston, W. Va.

Despite power shortage and car shortage, the mines in the Kanawha district succeeded during the week ended June 15, in increasing the total production in the field from 144,000 tons to 170,000 tons—an increase of over 25,000 tons—this being the largest production recorded in the Kanawha district for several months. With practically a full supply of cars in the field Monday the mines were at a standstill in many places with the power off, a number of the larger companies, such as the Cabin Creek Consolidated Coal Co., being compelled to shut down.

It was not through any assistance from the railroads that the mines in this district were enabled to increase their production, but because of the fact that the coal was moved out on barges. The inadequacy of the car supply is shown in the fact that 2037 hours were lost during the week ended June 15 through car shortage alone, labor shortage being responsible for the loss of only 151 hours. Operators claim that with anything like a fair car supply they will be able to materially increase production. The supply of cars for the present week has been much better than during last week, averaging about 70 per cent.

Mines reached by the Kanawha & Michigan Ry. received almost as many cars as they can load during last week.

Definite control of the Kanawha & Michigan and the Coal & Coke railroads, both of which are coal-carrying roads, seem certain in view of the visit here last week of C. H. Markham, regional director of the Allegheny regional district under the National railroad administration. If such does prove to be the case, it will work an improvement in the interchange of cars between the Kanawha & Michigan and the Coal & Coke railroads.

Fairmont, W. Va.

As long as transportation facilities in the Fairmont field are kept up to the mark at which they have been for the last few weeks, the production in that field will be most gratifying. Last week the supply of cars was sufficient to keep coal moving, there having been 1769 cars in the field Monday, 1561 Tuesday, when every mine was working, and an equally good supply Wednesday. Operators in the Fairmont district, as well as in other fields, believe, however, that the maximum supply will not be reached nor will it be possible to reach it until coal cars doing general duty on miscellaneous freight roads are ordered back to coal roads and used exclusively for the transportation of coal.

The car supply in the New River field during the week has fluctuated considerably, being good one day and bad the next. Furthermore, the operators are still bothered by the fact that they cannot depend on regular power supply. Of course, this does not apply to all the mines in the district, because there are several of the larger operations in the New River section which depend on their own power plants. Operators in New River territory have not so far given any attention to the question of greater efficiency in the mines, having been able to load all the cars they receive, but it is predicted by some of the operators in that district that when there is a full car supply operators will be hard put to load all cars. The same coal men say that there is little doubt of there being a coal famine this winter, and that the fact might as well be faced now.

Huntington, W. Va.

Twelve of the fourteen districts composing the West Virginia Coal Association were represented at the meeting of the executive committee at the Frederick Hotel, this city, on June 21. This was the first session of the committee since the reorganization a short time ago, and it was an eminently satisfactory one throughout. Discussion and action were all grounded on the proposition that the maximum production of coal is one of the most essential factors in warfare, and there was unanimity of sentiment that the fullest coöperation should be given the Government. This sentiment was put in concrete form by resolutions.

The association now represents the entire coal tonnage of the state, steam and gas. The two districts that were not represented at the meeting are likely to join within a short time, it was stated. Information given at the meeting leads to this belief, and there is no tenable cause for their remaining outside the fold.

The following officers were elected to serve for the ensuing year: J. G. Bradley, chairman, Dundon, W. Va.; G. H. Caperton, vice chairman, Charleston, W. Va.; A. H. Land, treasurer, Logan, W. Va.; W. H. Cunningham, secretary, Huntington, W. Va.

Marion, Ill.

A meeting was recently held here between the operators of Williamson, Franklin and Saline Counties and the district officials of the United Mine Workers from the same counties, and also the officials of the Central Illinois Public Service Co., together with its attorneys and Special Agent Horton, of the United States Fuel Administration, with a view to straightening out the difficulties encountered by the operators in the three counties in contending with the extremely poor service furnished by the Public Service Bureau.

The Government agent was evidently not so well informed about Illinois coal-mining conditions as he might have been, and the result was that the meeting was anything but harmonious. The operators and miners were opposing the Public Service Company and the Government official.

It developed that the Government plans had been approved of by the Public Service Company, who had seen them previously to the meeting. The plan proposed was that the mines curtail the power requirements in their contracts and take not to exceed 70 per cent. of same. It also developed that the Government wanted one mine to work one day and alternate in idleness with another mine the next day.

The operators and miners proposed that the power be cut off from all other industries in the field and give the mines the preference.

Another proposition was that the Interurban line between Eldorado and Carrier Mills be shut down during the day while the mines needed the power. The Public Service representatives stated that it would be impossible, for while the power company and the railroad were conducted by the same company, the bondholders of each were different and that the bondholders of the railroad would not permit the shutting down of their operations.

Another proposition was that the mines could get more power if they worked during the night hours instead of the day hours, and there were some extremely heated arguments, over which the Government agent got somewhat uneasy.

The meeting, after two or three hours of this kind of wrangling, broke up about as informally as it had convened, with nothing accomplished, only perhaps that some harder feelings existed between the Service company on one side and the operators and miners on the other.

Dallas, Tex.

Owing to a slacking up in orders for mine-run coal and the hearty response on the part of people of Oklahoma, Texas and other states to the appeal of the Federal Fuel Administration for the householders to purchase and store coal for winter use, there is now being developed a plan that has for its purpose the abolishment of all prepared sizes of coal and the production of nothing but mine-run. The plan is proposed for the duration of the war, and already has the approval of the Fuel Administration, officials of the United Mine Workers of America and coal operators of Texas and Oklahoma.

According to coal operators of the McAlester-Wilburton (Okla.) coal fields, the manufacturing industries have been slow in making purchases of coal for winter use. The private citizens who depend on coal for heating, it is said, have laid in their winter supply and such purchases are now negligible, but the manufacturing plants and other large industries have no coal on hand for winter.

It is claimed for the plan proposed that with the elimination of other grades and classes of coal except the run-of-mine, all the labor now required to separate the different grades of coal would be eliminated and the plan would make for continuous operation of the mines. The matter of loading coal on cars at the mine would also be simplified, as the mines would produce but one grade of coal and there need be but one loading system.

Victoria, B. C.

The Canadian Collieries (Dunsmuir) Ltd. has practically completed development work in connection with the opening of a new coal mine at South Wellington. The Douglas seam has been struck with a thickness of between 10 and 12 ft. at the face. On Monday, June 17, the new tipple, screening plant, etc., were in operation for the first time, and within a short time the output will be maintained, if expectations are realized, at between 750 and 1000 tons a day. The product of this company at both its Extension and Comox collieries, Vancouver Island, runs to about 70,000 tons a month.

The Canadian Western Fuel Co., of Nanaimo, B. C., has commenced operations on the sinking of a pair of shafts for the opening of a new mine on the company's farm near Nanaimo. These shafts are of ample dimensions, and are situated 150 ft. apart. They are being sunk to tap the Wellington seam and will mean the area southeast of Jinglepot mine. Extensive drilling operations have been under way for some time to prove the measures and locate the best position to place the shafts. Excavating of the surface subsoil to bed rock has been completed and concrete collars placed around the mouth of the shafts. Work on the hard stratified bed rock commenced on Monday, June 17. The seam will be uncovered at about 350 ft. depth, and if conditions are normal coal should be reached in about four months. The cost of opening and equipping will involve an expenditure of about $300,000. The company is producing upward of 70,000 tons a month from its mines now in operation and looks forward to a considerable augmentation of this total. This will make the third new mine opened in the vicinity of Nanaimo, Vancouver Island, during the past year, the other two being now in coal. One was developed by the Canadian Collieries (D) Ltd. and the other by the Granby Consolidated Mining and Smelting Company.

PENNSYLVANIA

Anthracite

Browntown—Several families have been notified by officials of the Pennsylvania Coal Co. to vacate their homes, as further caving is expected. During the past year a number of homes have been badly damaged in Browntown as a result of mine settlings.

Plains—Thirty-three full-fledged certified miners were among the 109 men from the 30 county exemption districts, with headquarters here, who left for Camp Lee, Petersburg, Va., on June 27. The list also contains numbers of men employed in and about the mines in the transportation and preparation of coal. Steps had been taken to obtain exemption for the miners called in this quota, but through a recent order of the provost marshal the board was instructed to include the men in this call.

Georgetown—For the second time within a week a large section of the surface of Northampton St., in front of the property of the Settlement Association, caved in on June 20. Traffic on the trolley line was stopped when the cave became serious. The cave caused the water mains to burst. The escaping water tended to hold up the side of the cavity, but after the water had been shut off from the mains the surface depressions extended over a considerable area. The cave is over old workings of the Empire No. 4 colliery of the Lehigh & Wilkes-Barre Coal Co.

Bituminous

Waynesburg—The Crucible Fuel Co. has purchased 52 acres of coal land in Cumberland township, Greene County, from J. Calvin Gwynn, for a consideration of $27,578.25.

Blairsville—The Davis Coal Co., operating several mines around Blairsville, is opening a new mine about two miles from town near Smith Station. The coal is the Pittsburgh vein and is 7 ft. thick at the new operation. Frank G. Davis is general manager of the company.

Coral—The Potter Coal and Coke Co. has started the construction of 12 additional houses at its plant here to care for the additional workmen which they are employing. These houses are of the bungalow type, similar to the ones erected by this company last year, when it took the Coral mines over from the Wharton Coal and Coke Company.

Harrisburg—According to a report issued by the Chief of the Department of Mines, Seward E. Button, there were 368 fatalities in the bituminous coal mines for the first five months of 1918, a decrease of 11 over the same period last year. There was an increase in the fatal accidents on the outside of the mines, however, over the same period last year. In 1918 there were 71 fatal as compared with 52 in 1917. Most of the outside fatalities were due to accidents by cars.

Indiana—One of the largest crowds ever present at an affair in Indiana gathered the other night in a patriotic celebration and "Clean Coal" campaign. Special trains and street cars were run on all the railroads to carry the miners from every mine in Indiana County to this city that evening. The chief speaker was John P. White, of the United States Fuel Administration, and former president of the United Mine Workers. Other speakers included wounded British and French soldiers who are in this country on leave. The miners pledged 100 per cent. efficiency and to load clear coal.

Uniontown—Disposition of $3,797,472.45 is shown in the schedule filed with the referee in bankruptcy of the sale of 1100 acres of Greene County coal land by the trustees in bankruptcy of J. V. Thompson, former coal baron and banker, to the H. C. Frick Coke Co. The schedule of distribution will be presented shortly to the United States District Court at Pittsburgh for approval. The court has already confirmed the sale and directed the transfer of the title. The magnitude of the sale is revealed by some of the minor items appearing upon the schedule. It takes $3678 in revenue stamps alone to convey the deeds to the property. The trustees of the estate will receive a commission of 1 per cent.

WEST VIRGINIA

Crumpler—United Pocahontas Coal Co. is installing a complete water-works system for its tenants.

Powhatan—The Pocahontas Coal and Coke Co. is installing a filtering system in connection with its water-supply line.

Coopers—The Mill Creek Coal Co. contemplates building new houses to take care of miners and increased production.

McComas—The American Coal Co. is installing sanitary septic tanks at each of its operations—Crane Creek, Pinnacle and Piedmont.

McDowell—The McDowell Coal and Coke Co. will build additional houses, preparing to take care of new miners and to increase their production.

Landgraff—Responding to the request of the Government for more coke, the Empire Coal and Coke Co. is rebuilding and firing up all ovens possible.

Thurmond—Picking tables are being installed at the mines of the Alpha-Pocahontas Coal Co. at Alpoca, the object being to insure cleaner coal.

Yolyn—The Paragon Coal Co. has recently completed the construction of a new tipple at its No. 2 mine here, costing $6000. Fifteen new houses are being built by the Paragon company at a cost of $15,000.

Fairmont—New officers have been elected by the Fairmont Coal Club for the period of six months. They are Brooks Fleming, president; Clarence D. Robinson, vice president, and Brooks S. Hutchinson, secretary.

Accoville—New shaker screens and a new loading boom costing $8000 have been added to the tipple of the Deegans Eagle Coal Co. of this place. The same company has also let the contract for ten houses to cost $10,000.

Ceredo—The Coal Branch Coal Co. of this place began operations last week according to an announcement made by Harry S. Stout, general manager. The equipment for the operation consists of a tipple and other mining machinery. Coal from the mines is to be conveyed by trucks.

Elkins—From being the smallest, the Grassy Run mine of the West Virginia Coal & Coke Co., at Roaring Creek Junction, has now become its largest operation, 25 cars of coal a day being shipped from this mine. A large number of houses of modern construction for the miners at this point have also been built recently.

Fairmont—The Trainor Coal Co. has sold its property on Coon's Run to J. W. Preston and associates of Johnstown, Penn., who took control June 18.

The Helen's Run and Bingamon branches of the Western Maryland R. R. are now supplied with cars from the Monongah division of the Baltimore & Ohio, and the reports of these mines are handled the same as other mines in the Fairmont district. Heretofore the Western Maryland has had specially assigned cars sent here by that line of railroad.

Grafton—The Hope Natural Gas Co., which has a byproduct plant at Downs and one at Hastings, in Wetzel County, is to erect another such operation near Moatsville in Barbour County. This announcement would indicate that the venture at Downs is meeting with the success anticipated. For several weeks past agents of the Pittsburgh concern (or men believed to act in such capacity) have been taking options on farms from the mouth of Raccoon creek where it empties into Teter's creek to a point two miles above Moatsville. More than a thousand acres of land has already been optioned, it is reported, at an average of $85 an acre. The rumor is that a $4,000,000 plant is to be erected on the J. O. Freeman farm two miles east of Moatsville, but the amount to be expended is probably a high estimate.

Huntington—The mining and shipment of coal from the mines of the Peter Cave Coal Co., on Coal River, will be begun early next month. D. J. Pancake is general manager of the company and Frank Kerns is superintendent, with headquarters at Alkol, W. Va.

D. C. Hewitt, his son, A. M. Hewitt, and R. A. Morris, who has been general superintendent of the Hewitt timber operations, were the principal figures in a coal deal consummated at Welch this week under the terms of which the producing mines of the Buck Creek Coal Co. and the Warfield Coal Co. were sold to the Easton Coal Co., and coal lands recently acquired by D. C. Hewitt were leased to the Easton company at a minimum royalty of $12,000, the coal lands being located just across the river from Kermit, W. Va. The purchasing company plans to invest $300,000 in additional equipment with the result that the development is expected to make it possible to produce 35 cars of coal daily.

Charleston—The West Virginia Coal and Coke Co., with general offices at Elkins, will in the near future open another mine in the Copen field, on the Coal & Coke Ry., near Bower, in the Pittsburgh seam, to be known as No. 12 mine. The plant to be erected will include a wooden tipple and other mine accessories.

The Royal Block Coal Co. at Dotson, on Coal River, is not only preparing to open up their No. 2 mine there at a cost of $20,000, but is also expending $10,000 on erection of a new tipple there.

The Carbon Coal Co., at its No. 2 mine, contemplates the construction of a coal-storage bin in which to store coal produced at times when cars are not received for loading. By doing this the company hopes to enable the miners to work every day. The same company has purchased and will install a box-car loader at its No. 3 mine within the next 60 days, and also in order to secure the highest quality of coal is building at its No. 6 mine a tipple with automatic scales, picking table, etc. The tipple is nearing completion.

INDIANA

Brazil—The Indiana Industrial Board has awarded judgment to Walter Griffith, of Coalmont, for $4,500, and he will draw $9.08 a week for 500 weeks. The judgment is to be paid by the Vigo Mining Co., for which he was working when injured by a fall of slate in a coal mine.

ILLINOIS

Pana—Coal rights under 33 acres of land purchased two weeks ago by Harry Tanner from the Hayward estate were sold a few days ago to the Smith-Lohr Coal Co. The coal rights were sold at $30 per acre. Besides the coal rights Mr. Tanner sold the coal company 15 acres of land adjoining the mine company on the west.

Decatur—This city has been much concerned over the order that coal can be shipped into Macon County. The mines of Macon County will not produce enough coal for the City of Decatur and the county, and much coal must be shipped in from other localities. The mines at Lovington, 20 miles east of Decatur, supply much of the coal which is shipped into Macon County. Decatur people have invested about $200,000 in the Lovington mines and wish to see the coal mined from Lovington for Decatur consumption. Much of the coal now being mined in Macon County is being stored in Decatur. A number of Decatur manufacturers have gone to Chicago to protest against the order against shipping coal in from other localities.

KENTUCKY

Heiner—The Daniel Boone Coal Co., which has offices in Columbus, Ohio, is activey at work on a new mine in the Hazard field. A modern tipple is being constructed and entries are being driven. It is planned to have an output of 2000 tons daily and the new mine will be opened by the first of the year. With the new mine the company will have three operations on the tract, two at Lennut and one at Heiner.

TEXAS

Santo Tomas—The big tipple of the Santo Tomas coal mines, 23 miles north of Laredo, Texas, was destroyed by fire and an explosion of unknown origin on June 5. The lives of 60 men who were at work in the mine at the time were threatened, but all were saved. The loss will amount to about $75,000, but the damage will be repaired at once and operation of the mine continued with but brief interruption.

Foreign News

Minto, N. B.—A party of American capitalists, including F. S. Peabody and W. H. Leland, representing the Peabody coal interests, recently visited the Minto coal field in company with Fuel Controller Magrath. Mr. Peabody was favorably impressed with the coal areas and expressed his willingness to spend $500,000 under favorable conditions. He subsequently conferred with Premier Foster, of New Brunswick, with a view of securing coal areas.

Personals

A. S. Hamilton has been appointed general mechanical superintendent over all the operations of the Canadian Collieries (Dunsmuir) Ltd.

H. R. Bissell, formerly with the Century Coal Co., of Baltimore, Md., has been made

superintendent of the Cambria Coal Co.'s two mines at Bellaire, Ohio.

John Dando has resigned his position as mine overman at No. 4 Mine, Comox Colliery, Canadian Collieries (D) Ltd., and has been succeeded by **Charles Pharnam.**

Thomas Taylor has resigned his position as mine overman at No. 5 Mine, Comox Colliery, Canadian Collieries (D) Ltd., and has been succeeded by **William Walker.**

P. A. Grant has resigned his position as state mine inspector of the Ninth District of West Virginia to accept the superintendency of the Sunbeam Coal Co., of Logan, W. Va.

William Roper, of the Morden mine, Pacific Coast Coal Mines, Ltd., South Wellington, B. C., has resigned and accepted a position with the Canadian Western Fuel Company.

C. J. Norwood and **F. C. Horton,** of Lexington, Ky., have been reappointed by Governor A. O. Stanley of Kentucky as state mine inspector and assistant mine inspector respectively.

F. E. Harriman, who for many years was coal traffic manager of the New York Central lines east of Buffalo, was last week elected vice president of the Clearfield Bituminous Coal Corporation.

Ralph M. Keeney has been appointed assistant general manager of the Thompson-Connellsville Coke Co. plants at Republic, Penn. He succeeds Andrew Thompson, son of J. V. Thompson, who has retired from the company.

W. Guy Srodes, for several years superintendent of the Cambria Coal Co.'s two mines in Bellaire, Ohio, has been promoted to assistant manager and placed in charge of operation of twelve mines at Athens, two at Zanesville and two at Bellaire.

A. H. Krom, formerly secretary of the American Association of Engineers, has been made director of the Division of Engineering, with headquarters at 29 S. La Salle St., Chicago, Ill. Through this division the Government will supervise the proper distribution and conservation of the technical service of the country.

H. K. Mack, for eight years commercial agent for the Burlington R. R., has been appointed supervisor of coal traffic for Southern Illinois by the Railroad Administration, through R. H. Aishton, divisional fuel administrator of Chicago. Mr. Mack will be located at Herrin, Ill., from which point he will supervise distribution of coal cars and coal traffic in the Southern Illinois district.

Obituary

James Wilson, aged 68 years, one of the best known mining men in northeastern Pennsylvania, died suddenly on June 18 at his home in Ashland, Penn. He was for 20 years superintendent for the Philadelphia & Reading Coal and Iron Co. in the Ashland district.

Dr. James Douglas, for many years president and lately chairman of the board of directors of Phelps-Dodge & Co., copper mine owners, died at his home in New York City on June 25 in his 81st year. Dr. Douglas was rated one of the foremost metal and mining authorities in the world.

Lorenzo D. Devore, chief deputy in the division of mines attached to the Ohio Industrial Commission, died at his home, Columbus, Ohio, June 24, from cancer. He was 55 years of age and had been connected with the Ohio mining department since 1908. He served most of the time as deputy inspector until about 15 months ago, when he was appointed chief deputy. He leaves a widow, four sons and three daughters.

Trade Catalogs

Hazard Wire Rope. Hazard Manufacturing Co., Wilkes-Barre, Penn. Price List No. 18. Pp. 49; 4½ x 7¾ in.; illustrated. Describes the several kinds of wire ropes manufactured by the concern and gives tables of prices, weight per foot in pounds, approximate breaking strain, etc.

Jeffrey Retarding Conveyors. Jeffrey Manufacturing Co., Columbus, Ohio. Catalog No. 232. Pp. 32; 8½ x 11 in.; illustrated. The catalog contains complete information regarding the construction and operation of Jeffrey retarding conveyors, as well as numerous illustrations of successful installations.

Strom Bearings—Data Sheets. U. S. Ball Bearing Mfg. Co., Chicago, Ill. Pp. 68; 4¼ x 7¼ in.; illustrated. The data sheets are so compiled as to furnish in a convenient form essential information regarding the dimensions of all types of Strom bearings. A revised list of prices in effect on and after Apr. 22, 1918, is also included.

Sullivan Rotators. "DP-33," "DR-33." Sullivan Machinery Co., Chicago, Ill. Bulletin 70-F (replacing 70-A). Pp. 28; 6 x 9 in.; illustrated. The rotator described in this bulletin is claimed to be an "all around rock-drilling machine." It is equipped with automatic steel rotation, is built in separate air and steam types, and may be used as a hand tool or on a mounting.

Illustrated Book of Parts and Accessories. Ironton Engine Co., Ironton, Ohio. Illustrated, 9½ x 11 in. The book gives a list of parts for locomotives, storage batteries, motors and accessories for the Ironton storage battery locomotive. Standard parts are shown for both A and D types, while parts used exclusively in either type and parts for motors and controllers are shown in separate sections. The Ironton company evidently went to considerable trouble and expense to prepare this book, a copy of which will doubtless be of considerable worth to users of Ironton equipment.

Industrial News

New York, N. Y.—The Wilputte Coke Oven Corporation has removed its offices and engineering department to the Winfield Building, 469 Fifth Ave., northeast corner of 40th St., New York City.

Orange, N. J.—The Edison Storage Battery Co., manufacturer of storage battery locomotives, etc., has opened a Philadelphia sales office at 740 Land Title Building. J. A. Hurst, sales engineer of the company, is in attendance.

New York, N. Y.—John F. Bermingham, president of the Delaware, Lackawanna & Western Coal Co., who is the representative in Greater New York of the Anthracite Committee of the United States Fuel Administration, has had his jurisdiction extended so as to include all of Long Island.

Kansas City, Mo.—The Southwestern Interstate Coal Operators Association, at its annual meeting recently, elected for continued service the officers who had held the places during the past year. F. W. Lukins was reëlected president. W. P. Hawkins, of St. Louis, was reëlected vice president at large; C. N. Fish, of Leavenworth, Kan., was reëlected secretary, and George Manual assistant secretary and treasurer. W. L. A. Johnson, was reëlected general commissioner.

Louisville, Ky.—According to figures recently compiled by W. B. Bryant and G. H. Sowards, of the Kentucky fuel administration's office, Louisville annually consumes 1,672,052 short tons of coal, of which 1,003,052 short tons represent domestic coal and 660,000 tons represent steam coal. This is taken from the annual receipts by rail and river on an average over a five-year period. The annual coal consumption for the state is given at 5,606,475 net tons.

Columbus, Ohio—A ruling has been announced by the Railroad Administration which effectually puts Ohio wagon mines out of commission. The new ruling supersedes a recent order that wagon mines are to be supplied with open-top cars only after all tipple mines secure 100 per cent. supply. Under the recent ruling no open-top cars are to be given wagon mines under any consideration. Unless they use box-cars the mines will have to suspend operations entirely.

Toledo, Ohio—Activity at the docks for the loading of lake coal kept up fairly well during the past week, although the total loaded by the Hocking Valley and Toledo & Ohio Central docks was not so large as during the previous week. During the week ending June 21 the Toledo & Ohio Central docks loaded 71,000 tons as compared with 79,000 tons the previous week. The total since the opening of navigation is 555,000. The Hocking Valley Docks loaded 144,634 tons as compared with 160,713 tons the previous week, making a total for the season of 1,036,927 tons.

Clarksburg, W. Va.—A. Lisle White discussed a phase of the labor question at a recent meeting of the Clarksburg Coal Club which has been emphasized by developments since that time, not only in coal circles, but in other lines of industrial activity. Mr. White referred to "registration dodgers," whose method of evading military service is to move from one state to another, working in mines, and avoiding registration by frequent changes of names. Since Mr. White's talk there have been developments which indicate that such a course will be almost impossible under regulations now being considered.

Fort Worth, Tex.—The coal operators of Texas met at Fort Worth last week and apportioned among the various Texas mines the amount of coal required by the Government, estimated at 60,000 tons. The agreement among the operators was prompt, and all promised hearty coöperation with the Government in every way possible. Among the Texas operators who attended the meeting were W. H. John, of Bridgeport, assistant district fuel administrator; E. S. Britton, Texas and Pacific Coal Co., Thurber; Judge E. B. Ritchie, Strawn; L. Wueste, of the Olin Coal Co., Eagle Pass, and W. F. Nance, Newcastle.

Christiansburg, Va.—C. C. Mathey, formerly of Galena, Ill., has been elected president of the Anthracite Coal Corporation, recently organized and incorporated here. The company is composed chiefly of men from Illinois and Wisconsin. According to the plans of the company, as outlined by President Mathey, about 3500 acres of coal land are to be thoroughly developed, the machinery for which work has been bought and is now being installed. It is expected to make the output of the mines for this year fully 300 tons per day. This is to be increased in 1919 to 500 tons per day, and after that time to 1000 tons per day.

Cincinnati, Ohio—The E. L. Sternberger Coal Co., of West Virginia, has filed suit in the United States District Court against J. F. Scherer and H. W. Mountain, of Lawrence County, Ohio, for $16,303.30, alleged to be due for breach of contract for the delivery of coal. The Sternberger company alleges that in March, 1917, the defendants agreed to deliver to the company the entire output of their coal mine from May 6, 1916, to May 6, 1918, at the rate of not less than 350 tons a week, but that a shortage of 10,868 tons between the contract and the coal actually delivered occurred, occasioning the claim for damages.

New York, N. Y.—The New York Coal Barge Operators' Association has issued the following demurrage rules for this harbor: "Two days to be given at the loading ports to load the barge and three days at the destination for unloading. At the expiration of the lay days, a charge of 3c. per ton on the full cargo capacity of the boat as per bill of lading to be charged for each and every day, over the lay days, $12 per day minimum. Sundays and holidays to be excluded from the lay days, providing coal piers or consignee are not working, but each day to count after the lay days are up. Twenty-four hours to constitute a day."

Louisville, Ky.—In the case of R. E. Boyd against the Petersburg Coal Mining Co. and J. W. Lam, the court dismissed plaintiff's petition, and gave the defendant judgment on a counterclaim of $763.89. Boyd sued for $45,436.11, alleging breach of contract made Apr. 26, 1916, to sell coal in the Falls Cities for the company, he to sell 300 cars the first six months and 600 cars the latter six months, but after delivering 60 cars the company broke its contract. The counterclaim was made on the grounds that plaintiff failed to pay for coal shipped. He admitted that he had not paid for it, and the court held that he violated the contract thereby.

Cincinnati, Ohio—Through a recent order of the U. S. Circuit Court, John S. Jones, of Columbus, has purchased all the outstanding stock of the Sunday Creek Coal Co., and all the legal complications which have been a source of litigation for more than 10 years are now cleared away. In the order the court approved a contract entered into between John S. Jones and the Hocking Valley Ry. Co. to take over $2,606,000 face value of bonds at 25c. on the dollar. The purchase of these bonds perfects the title to 25,000 acres of coal lands in Athens, Hocking and Perry Counties in the heart of the Hocking Valley producing field. Several years ago when Mr. Jones purchased the property it had $14,000,000 against it in bonds. Among other bondholders were the Kanawha & Hocking Coal Co., the Continental Coal and Coke Co. and the New York Central Railway Co. The bonds of the coal company were redeemed largely by the transfer of property for which the bonds were originally given as payment. Since Mr. Jones has acquired the clear title to the property steps will be taken to reorganize, taking the name of the Sunday Creek Coal Company,

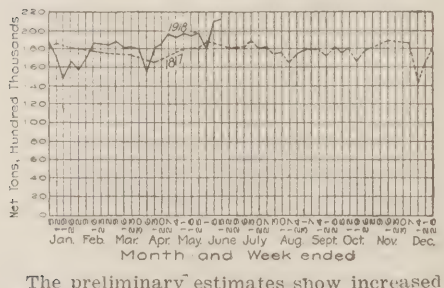
MARKET DEPARTMENT

Weekly Review

Nothing New in Market Conditions—Demand Urgent and Stocks Low—Bituminous Coal Production Exceeds All Previous Figures in Spite of Car Shortage—Anthracite Labor Problem Serious—Coal Shipments to Northwest Behind Schedule

AN ANALYSIS of coal-market conditions the past week discloses nothing of a startling nature. The competitive features which in former years dominated the news and added the spice of variety to the task of the reviewer are lacking in these days of Government regulation and administration. The statement that "Demands for all kinds of coal are urgent with stocks inadequate," though somewhat stereotyped by now, is nevertheless as true this week as it has been for weeks past.

The impetus given to coal production by the pulling together of the railroad and fuel administrations was reflected in the truly wonderful accomplishment of the bituminous coal mines during the week ended June 15, when 12,571,000 short tons of soft coal were mined. This output breaks all previous records and is deserving of more than passing notice when it is considered that a serious car shortage still exists; that thousands of experienced miners have been taken by the draft, and that labor conditions in general are demoralized.



Anthracite production for the week under review totaled 41,960 carloads, the best showing that has been made in many weeks. The labor problem at the hard-coal mines continues to cause much uneasiness, as this branch of the industry is losing men at the rate of 2000 monthly. Steps are being taken to have the Government give relief to a condition which promises to become critical unless the proper remedies are applied speedily.

While the tonnage of anthracite for May was but slightly less than the quantity shipped in May, 1917, yet it must be emphasized that the increase in steam sizes produced from banks—or culm piles—was the only thing that kept the aggregate production near that figure. The output of fresh-mined coal will continue to diminish just as long as labor at the mines diminishes.

Many of the larger operators are now shipping their entire output to the lakes, thus necessarily reducing the stocks available for steam and domestic use. The vessel movement is generally good, and a considerable tonnage is going to the Northwest. On the whole, however, shipments are behind schedule, principally because of the late opening of navigation.

COAL PRODUCTION

Production of bituminous coal during the week ended June 15 equalled and even exceeded the record production of the week preceding. The output of soft coal (including lignite and coal made into coke) is estimated at 12,571,000 net tons, an increase over the week of June 8 of 170,000 net tons, or 1.4 per cent., and over the current week of 1917 of 1,137,000 net tons, or 10 per cent. The average production per working day is estimated at 2,095,000 net tons as against 2,067,000 net tons during the week of June 8 and 1,906,000 net tons during the week ended June 15, 1917.

The preliminary estimates show increased production during the past week in central Pennsylvania, Tennessee and Kentucky, and Alabama. Central Pennsylvania production increased 4 per cent., Tennessee and Kentucky 5 per cent. and Alabama 5 per cent. Material decreases occurred in the Pittsburgh and Panhandle districts and in Ohio. In the former fields 10 per cent. less coal was produced than during the week preceding and in the latter fields 7 per cent. less.

Anthracite shipments totalled 41,960 carloads, an increase of 206 carloads, or 3 per cent., during the week ended June 15.

Beehive Coke—Beehive coke production in the United States for the week ended June 15 is estimated at 658,000 net tons, an increase over the week preceding of 22,000 net tons, or 3.5 per cent. The average per working day reached 110,000 net tons, the highest daily average during the past three weeks. The principal operators in the Connellsville, Greensburg and Latrobe districts of Pennsylvania report production of beehive coke during the week ended June 15 at 391,070 net tons, the plants being operated at 77.2 per cent. of their present capacity, identically the same ratio as the week preceding. During the week slight improvement was reported in labor conditions, but such improvement, however, was offset by slightly greater car shortage. The same operators produced 190,550 net tons of coal.

CARLOADS OF COAL ORIGINATING ON PRINCIPAL COAL-CARRYING ROADS

	Week Ended May 25	June 1	June 8	June 15
Bituminous shipments, 123 roads.	207,036	187,875	219,839*	222,432†
Anthracite shipments, 9 roads.	40,594	31,762	40,754	41,960†

* Revised from last report. † Subject to revision.

Byproduct Coke—During the week ended June 15, little change was exhibited in operating conditions of the byproduct industry. Slight improvement was reported due to repaired plants and to better market conditions, the plants of the country being operated at 88.5 per cent. of their present capacity—the highest point since May 25. Material increases in production are reported by Alabama, New York, Tennessee and New Jersey. The improved production in Alabama and New York is attributed to repaired plants, in Tennessee to better supply of byproduct coal, and in New Jersey to both improved coal supply and repaired plants. Massachusetts was the only state reporting a material decrease in production. The decline is attributed to repairs to plant. Labor conditions in Pennsylvania show no improvement, while slightly better market conditions existed in Minnesota.

BUSINESS OPINIONS

Dry Goods Economist—Strikes of operatives in spinning plants have reduced the week's production of wool and worsted yarns. Production of most lines of dry goods bids fair to be curtailed by the Government plans as to restriction of fuel supply. Transportation delays continue to retard the delivery of goods to merchants and of raw materials to manufacturers. The indications are, however, that transportation westward from territory near the eastern seaboard, where the bulk of the country's manufacturing plants are located, will improve as the Government's plans for relieving freight congestion mature.

Bradstreet's—Potentially, civilian demand is of large volume, but inability to find free merchandise in large quantities naturally lessens the power of sellers to fill orders, and as most markets are dominated by the exigent needs of the Government, trading is being conducted in the confirmed belief that deliveries can only be had when and as the war situation becomes less imperative. On the other hand, movements in such important lines as textiles are somewhat crimped by the uncertainties arising from price stabilization, lack of knowledge as to its final effects rendering it necessary for sellers as well as buyers to temporarily mark time, as it were.

American Wool and Cotton Reporter—As long as importations of wool continue there will probably be a reasonable supply, but if developments make it impossible to keep up importation, or if they become negligible, the situation with regard to even Government production might be affected seriously. The supply of wool is not overlarge for any particular plant, and possibly manufacturers are working on a narrower margin than they are used to; but machinery is being kept in operation up to the limit. In many ways the recent conferences between the representatives of the Government and manufacturers have had a restricting effect upon business. There is every reason for conservative buying because the entire problem has not yet been settled. The sooner the prices are definitely fixed and the sooner the details are established, the better it will be for the market.

The Iron Age—The disappearance of Chicago as a basing point for bars, plates and shapes is an important outcome of the Washington conference. The 25 per cent. freight advance adds to the advantage a sole Pittsburgh basing brings to Central Western and Eastern mills that for nine months have had to absorb freights to Chicago. The change was due in part to the fact that Chicago mills are loaded up, so that 200,000 tons of ship steel for the Pacific coast must be rolled in Youngstown, Pittsburgh and farther eastern mills. With no definite system of pig-iron priorities, furnace companies are making shipments largely to foundries working in essential lines. Contract deliveries are going by the board in many cases and other foundries designated from Washington are get

ting iron. England's order for 180,000 tons of basic iron, to be shipped in September, October and November, is likely to be divided between the North and the South. If silicon tolerance is raised to 1.25 per cent. the South can take more, with the advantage of shipping from Southern ports.

Marshall Field & Co.—Merchandise billed for both current and future delivery shows a large increase over the corresponding week of a year ago. Road sales for both immediate and future delivery are in excess of those of the same week in 1917. Customers have been in the market in fewer numbers. Collections show a satisfactory increase over the corresponding period last year. The domestic cotton market is firm.

Atlantic Seaboard

BOSTON

Clamor from other sections about all the coal going to New England not borne out by the facts. So far movement is but slightly improved over May figures. Continued anxiety over outlook. Railroad stocks diminish instead of increase. Valuable time lost. Grain shipments to start by July 15. Bottoms at Hampton Roads not yet resumed, schedule and dumpings slow. Baltimore & Ohio deliveries cease to come through all-rail and for New England destinations are likely also to be "zoned" via Curtis Bay piers. Lean arrivals by water. Fuel authorities begin wholesale diversions under new distribution plan. New Lake-built steamers appear on coast from week to week. Anthracite steam sizes come forward in good volume. Buying increases to such extent that tonnage available will probably be less and less as season advances. Rail shipments of domestic sizes show fairly well but water receipts are still sluggish.

Bituminous—The order dated June 10 directing the district representative at Altoona to ship to New England on the basis of 4500 cars as a weekly quota has apparently given other sections an attack of heart-burn, although thus far the "order" is going into effect with extreme slowness. If the coal were shipped as provided on paper, the share of this territory for "commercial coal" would be less than 20 per cent. As it is, neither the Shipping Board nor eastern Pennsylvania has occasion for anxiety, considering the very thin yield the order has as yet produced for New England. There seem to be hitches in the program, and while the latter has apparently been approved by the Railroad Administration, there are still some traffic questions to be smoothed out. Meanwhile, this territory drops farther and farther into arrears as compared with a year ago, and the task of equitable distribution becomes increasingly complex. Experts from Washington decided early in the year that 30,000,000 tons should be New England's quota, and it is only our portion of the 30,000,000 that should come to this territory from central Pennsylvania that Mr. Storrow is trying so hard to secure.

As a check on the actual volume moving through the five gateways, it appears that the best recent day was June 20, 661 cars. The average, however, for 21 days was only 490, a matter of but 20 cars daily increase, and this from all the producing districts now open to all rail destinations for New England. The most recent "New England order" was to build up the total movement from central Pennsylvania to 4500 cars weekly, including railroad fuel and every other requirement; in other words, an average movement of 1700 cars weekly from that district was to be raised, 2800 cars or nearly 165 per cent. Conservative opinion does not hold that any such increase is probable, and the 4500 are doubtless destined to be as famous as the order of Jan. 3 for 500 cars daily, which actually yielded in excess of 300 cars on only one day and showed an average for something over 100 days of 100 cars per day. The numerical designations applied to these orders are something for eager consumers in other sections to conjure with.

That buyers here are in a state of genuine alarm over the outlook has become a trite saying, but the days go on and still slim receipts from every quarter. Important activities are operating on very narrow stocks and consumers generally are dazed. There are so few directions toward which they can turn and each source of supply seems a little less dependable than the others. Conservation measures are being well supported and some surprising progress has been made.

The railroad fuel situation is particularly urgent. One of the larger roads is repairing storage plants and is able to run on current receipts, but others, like the Boston & Maine and the Boston & Albany, find daily receipts actively inadequate and are making further and further inroads into storage. If relief is not had within a few days, one of the systems will be obliged to confiscate coal in transit. This only shows the extent to which the New England situation has been allowed to drift. The May average for fuel coal daily through the five gateways was but 98, while the average for 20 days in June was practically 110 cars, a gain of only twelve.

Boat arrivals at Hampton Roads are still irregular. On June 21 the dumping dropped to less than 13,000 tons, the highest day since the 16th having been 35,000 tons on the 19th. Against a normal tonnage of 60,000 tons this seems rather a poor showing. The June total for New England will therefore be considerably less than the May figures, and New England receipts will be that much farther behind. At all times recently there has been a surplus of coal over bottoms, and not yet have the Hampton Roads shippers felt very seriously the shortage of labor.

Loadings at Baltimore, Philadelphia and New York show slight increase over May, the total tidewater tonnage from all ports for New England for the first 21 days in June amounting to more than 900,000 tons. Shipments all-rail from the Boston & Ohio and Western Maryland have practically ceased to New England points and the increased volume over the Baltimore piers is beginning to materialize. From the ships operated by the Shipping Board and subject to allocation by Mr. Storrow's committee of shippers a considerable allotment was made this week for Baltimore loading and it is likely this movement will increase materially as the season advances. Receipts at all the rehandling piers here are light, several of the distributors being hard put to it to meet the current needs of consumers who look to them for supply. One of the results of this scarcity of water coal is the renewed activity on the part of the fuel authorities in diverting coal in transit all-rail. A liberal use of this power is contemplated by the new distribution program and the flow of coal is bound to be closely watched under these circumstances.

Each week more of the new lake-built steamers appear with cargoes of Cape Breton coal, discharge and go to the loading ports to join the coal fleet. That is one of the few encouraging signs in the coastwise trade, and it is quite possible that during August receipts will show a decided increase through this additional cargo space and the increased movement via the Baltimore piers.

Prices at Boston on the smokeless coals are still on a high basis. Recent cargoes of New River have sold all the way from $8.35 @ $9.90 f.o.b. cars Boston for distribution inland, the range varying with demurrage and other contingent charges.

Anthracite—The average movement of steam sizes of anthracite through the five gateways for 21 days in June was 183 cars daily, as compared with a daily average of 558 cars of domestic sizes. The rail movement begins to show the result of instructions a fortnight ago to increase shipments in that direction. Water shipments are still held down by the precautions being taken in the forwarding of tows. It is a great pity that the most favorable weather of the year cannot be used to greater advantage.

NEW YORK

Anthracite shipments short and lack of supplies causes dealers to worry. Consumer with winter coal in bin considered fortunate. Miners continue to leave operations and further appeals are to be made to Washington. Increased freight rates become effective. Dumpings of anthracite and bituminous show increase.

Anthracite—The situation, with receipts of fuel comparatively light, continues to be a source of worry to the trade. At this time of the season, when retail dealers should be filling their yard bins for next winter's drive, they are practically without any coal and the prospects are not encouraging. Fortunate, indeed, the dealers say, is the household consumer who has the whole or any part of his winter's fuel in his cellar bin. With an urgent demand from all sections of the country where anthracite shipments are permissible, this market is not in a position whereby it can expect to obtain more than its allotment of tonnage.

The increase in freight rate of 30c. per ton ordered by Mr. McAdoo, Director General of Railroads, went into effect on June 25. This makes the freight rates to the lower ports $1.85 per ton for the sizes above pea coal and $1.75 per ton for pea coal and the smaller sizes.

The heavy demand for coal is having its effect upon the stock market. A contributing reason for the steady buying of the anthracite coal stocks may be found in the much higher prices some of the smaller sizes of coal now bring.

The report of dumpings at tidewater for the week ended June 24 shows 7245 cars of anthracite dumped as against 7131 cars dumped the week previous, an increase of 294 cars, while there were shipped from the mines during the week ended June 15 41,960 cars, an increase of 1206 cars, or 3 per cent. over the preceding week.

Governor Whitman's attention has been called to the failure of Dr. Garfield to appoint a successor to former State Fuel Administrator Wiggin. The Merchants' Association has interested itself in the matter, while the trade is anxious that the vacancy be filled quickly.

Supplies of the domestic sizes have made no appreciable increase. While statistics show a larger number of cars dumped here, considerable of this coal went to other sections outside of the Metropolitan district.

The buckwheat coals are in good demand, and there is a good supply. Some of the companies are enabled to store small quantities of barley, but this tonnage is not large. Culm is being offered freely, but as a rule is only purchased by those who are able to obtain bituminous.

Current quotations, per gross ton, f.o.b. tidewater, at the lower ports are as follows:

	Circular	Individual		Circular	Individual
Broken	$6.75	$7.50	Buck	$5.15	$5.90
Egg	6.35	7.10	Rice	4.65	5.10
Stove	6.60	7.35	Barley	4.15	4.30
Chestnut	6.70	7.45	Boiler	4.60	..
Pea	5.20	5.95			

Quotations for domestic coals at the upper ports are 5c. higher on account of the difference in freight rates. Prices for buckwheat, rice, barley and boiler are not fixed by the Government.

Bituminous—Conditions are slightly improved, due to a better car supply and transportation facilities. At this market receipts show a slight increase and movement was better, but there are no free coals to be picked up by the spot buyer. Regular customers are obtaining a better supply, but far from what they want.

There were dumped 7239 cars during the seven days ending June 24, as compared with 6630 cars the previous week, an increase of 609 cars. Government statistics show that during the week ended June 15, 222,432 cars of bituminous were shipped as compared with 219,839 cars during the week ended June 8, an increase of 2793 cars. It is also reported that production last week increased in the central Pennsylvania district.

The effect of the increase in freight rates which became operative on June 25 will not be felt immediately in the trade owing to Dr. Garfield's order that the increase shall not be added to any coal now on hand and that it may be included only in prices charged for coal upon which the higher rate actually has been collected by the railroads. The increase will mean an advance of from 40 to 50c. per ton on tidewater coal, depending upon the district from where the coal comes. It is understood that one road has announced that its rate to this tidewater will be $2.15 per ton, an increase of 50c. over the previous rate. Shippers are, however, uncertain as to what the increase is and are awaiting definite information from the proper authorities.

PHILADELPHIA

Anthracite tonnage heavy to New England. Local dealers expect heavy shipments later. New freight rates effective June 25. Unfilled retail orders pay higher prices. Steam trade disturbed. Buckwheat on retail preferred list. Dealers object to stopping bag deliveries. Coal solves rent profiteering problem. Labor supply hinders production. Bituminous trade dissatisfied with New England preference order.

Anthracite—To record local conditions recently is to tell of empty yards, disgruntled dealers and an impatient public. The New England market continues to have the call, and while all houses continue to ship heavily, one of the big companies practically shipped its entire production of prepared sizes there toward the latter part of the month.

We have recently interviewed a number of dealers, who are leaders in the trade, and who profess to believe that after the middle of July shipments to this city will be materially increased. It is becoming quite apparent that some radical move

must soon be made if the dealers are to make any material reduction in the heavy tonnage domestic coal orders which have remained unfilled since early spring. As the receipts of many dealers during June ran behind their allotment it will be necessary to make substantial shipments here during July if next month's quota is to be finished and this month's shortage made up. This is not allowing for any increase, the details of which have not as yet been announced, but for which the dealers are anxiously waiting.

The new freight rates went into effect on the 25th inst., and on domestic coal amounts to an increase of 45c. a gross ton, which makes the rate on the bulk of the coal reaching this market $1.95, although on shipments from some of the other regions it is $2. and $2.11. This increase has placed the dealers in an even more difficult situation as to the deferred orders on their books. It is absolutely certain that hundreds of orders will remain unfilled by Sept. 1, when the fall increase in the price of coal goes into effect to the amount of 30c.; and this with the freight increase of 45c. makes a total increase of 75c., which they will have to explain to innumerable customers. Of course, the dealers are protected as to price, but that does not make their task the less easier in explaining the situation to customers who expected the coal in their cellars months ago at the lowest price in effect.

The steam business is in a state of chaos, and it is understood will be further disturbed. This week the local administrator issued a circular letter addressed to all the Philadelphia dealers, advising them that No. 1 buckwheat had been placed on the preferred list by the U. S. Fuel Administrator and forbidding them to store more than one day's requirements at any plant without a special permit from the local office. In the same letter the dealers were advised to deliver no coal of any size to private garages, whether occupied partially as a dwelling or not, nor to private greenhouses. They are informed that in the autumn it will be determined whether such buildings are to be allowed to receive any coal.

The local trade has also been much upset to learn of the desire of the municipal sealer of weights and measures to prohibit the further delivery of coal for domestic use in bags, which has become quite popular in the residential sections in recent years. The city officer argues that in times of scarcity of coal it makes it too easy for drivers to yield to the temptation of disposing of a bag or so before the coal reaches the cellars of the buyers. A committee composed chiefly of surburban dealers called on the dealer and explained to him if only because of the extremely high cost of bags they would be glad to give up the practice. The difficulty is that in the suburbs a great proportion of the coal cannot be chuted, even if they had the equipment, which at this time they are unable to provide. The wagons now used for this bag business would be useless, and they appealed against any such action being taken at present. The question is still in abeyance.

Chairman Lewis of the local fuel administration has made a ruling that has endeared him to many householders. With the army of new workers now in the city there has been much trouble finding homes to accommodate them. This has led to quite a scandal, as profiteering landlords have been promiscuously raising rents and refusing to give leases for more than a month at a time. Under these conditions most people were afraid to order a winter's supply of coal, for after getting the coal in the rent might be raised to prohibitive figures and they be compelled to vacate. Plans were put in operation to secure national legislation to correct the evil, but the chairman came across with a simple plan that bids fair to effect a cure. Landlords are warned that if they refuse to give a lease until next April to any tenant who fulfills his part of the obligation, no coal will be permitted to go into the house before Apr. 1, 1919. Mr. Lewis made the statement plain when he said the property owner who tried to put the tenant out without cause other than his desire to profiteer will find himself with a property on his hands for which no fuel can be obtained. He is also on record as ruling that any landlord who will not put the heating apparatus of a house in condition to burn coal economically will be compelled to do so.

The labor situation at the mines continues to cause much uneasiness, as there is an average monthly decrease of about 2000 men. Steps are being pressed all the time to have the Government give relief to a situation which will eventually become critical. While the tonnage for May was but slightly less than a year ago, yet it must be recalled that the increase in steam sizes produced from banks was the only thing that kept the aggregate production near that figure. The production of fresh-mined coal will continue to diminish just so long as labor at the mines diminishes.

Bituminous—The shippers continue to remain dissatisfied at the New England preference order. The shipment of 900 cars a day to that region, they claim, badly disrupts their business connections in this vicinity. They stand in the position of being desirous of giving all their trade, wherever located, at least a fair proportion of the output. The car supply has fallen off considerably during the past week, as many shippers report only a 60 per cent. supply, although it is admitted that if the supply were 75 per cent. of rating it would be about all the operators could load on account of the labor shortage. The brokers continue to receive a fair proportion of coal

BALTIMORE

Steady improvement noted in character of bituminous shipments, which, however, are lighter. Anthracite situation far from satisfactory to trade or public.

Bituminous—There are two outstanding features to the soft-coal situation here at present. One is that the shipments to this territory have lightened, principally because there have been less diversions, whether due to improved railroad movement or other causes. The other is that there has been less complaint by far as to the quality of the coal coming through. The Government is growing more and more to regulate the shipment of coal from the mines in regard to quality and not merely to depend upon rejections at tidewater pools. The result has been that the jobbers here have been called upon to dispose of less of the rejected coal; not always an easy matter where customers can see the prospect of getting any better grade coal at the same Government figure. It may be remarked that while the industrial world here absorbed the coal diverted to the section, there was lacking any element of rush that might have been expected. The business world has apparently in many cases failed to take to heart the lessons of short supply of last winter. The Government order that the new increase in freight rates is not to touch coal already shipped or held in stock will not affect any great quantity of fuel here as there is not much of an accumulation at any point.

Anthracite—The order on freight rates applying to hard coal is likewise not destined to hit much tonnage, as the receipts here have been so far behind distribution needs that there is practically no coal in yards in this city. The Baltimore Coal Exchange has held several meetings recently to discuss the proposed freight-rate increase and its application to the public, as well as the railroad administration rule which requires that coal consignments be delivered only on surrender of original bills of lading and payment of charges; with a certified check for 110 per cent. to be filed in case bill of lading is lost or delayed. The Exchange has been bitterly opposed to the application at this time of both the rule which raises freight rates and consequently the cost to the consumer of anthracite, and to the bill of lading restrictions before delivery of coal. The receipts of hard coal here are a great disappointment. For April, May and June the total deliveries here of hard coal will not total much more than 180,000 tons, which is below last year's receipts for the period. This in spite of the fact that the Maryland fuel administration had asked for about a 20 per cent. increase for the year and had been promised an allotment of 10 per cent. increase, is disappointing. With more than 300,000 tons on the books undelivered and with orders still pouring in and which will run to around 600,000 tons before summer is over, there is no chance apparently of giving the public anything like the two-thirds supply which had been planned. Some new method of curtailment in early deliveries may now be worked out.

Lake Markets

PITTSBURGH

More complaint of labor shortage. Expansion of draft age limits may help. Prospective shortage of coal increased.

There is more complaint of labor shortage, which is coming to be recognized as a greater restrictive influence than was estimated recently, the shortage of cars covering up the labor shortage. Scrutiny of conditions indicates that if full car supplies were furnished—miraculously furnished, according to the views of most operators—it would not be possible to produce much more coal.

Considerable interest has been taken in the representations of the Provost Marshal relative to expanding the draft age limits. Hopes are entertained that if there is such expansion the "work or fight" doctrine will be more vigorously carried out and it will of course have a wider scope, as taking in a larger proportion of the coal-mining labor. Much attention also is being directed to the liquor question, and it is held that the Washington authorities should take drastic action in this matter, as they have in so many others.

While coal production is in the main increasing slowly, it is not increasing as the requirements are increasing with the constant speeding up of war work, and serious shortages are now more clearly in prospect than they were a few weeks ago. The coal-mining industry should be seeing the palmy days of the year just at this time as regards production and that is not the case.

Complaint is made by many manufacturing consumers in the immediate Pittsburgh district that on account of their nearness to the mines they are required to take a considerable part of their supplies by truck, paying a trucking charge usually of $1 a ton, when their freight rate would be 40c. or less. Their nearness to coal mines thus operates to their disadvantage, as their cost is increased, while that of consumers with a straight rail shipment is unchanged.

There is only a moderate amount of free coal developing, and only in small lots. Brokers are readily able to collect their 15c. brokerage on such free coal as they can find. Regular prices remain as follows: Slack, $2.10; mine-run, $2.35; screened, $2.60, per net ton at mine, Pittsburgh district.

TORONTO

Coal supply far short of requirements. Dealers refuse to accept orders. Outlook considered serious. Coal dealers' representative trying to receive additional deliveries.

The outlook for next winter's supply of coal is considered serious. Citizens who are in a position to pay for a supply are generally desirous of laying in stocks, not merely for fear of a shortage, but in anticipation of a rise in prices; but most of the dealers continue to refuse all fresh orders. It is estimated that the quantity of coal so far delivered this season is from 30 to 40 per cent. short of that on hand at this time last year. The order of the Fuel Controller limiting each consumer's supply to 70 per cent. of normal is generally well observed. H. A. Harrington, of the Coal Dealers' section of the Retail Merchants' Association, has gone to Pennsylvania to try and arrange for an increased supply for this city.

Quotations for best grades per short ton are as follows: Retail anthracite, egg, stove nut and grate, $10; pea, $9; bituminous steam, $8.50; slack, $7.50; domestic lump, $10; cannel, $13; wholesale f.o.b. cars at destination, three quarter lump, unprepared, $6.11; prepared, $6.31; slack, $5.18.

BUFFALO

Scarcity of anthracite locally is complaint. Bituminous moving about as usual. Conflicting reports as to miners working. Lake shipments keep up.

Bituminous—The situation does not change materially. Reports come in of cars discovered idle, but the fact seems to be that more coal is moving than ever before. From the Ohio ports come stories of lack of cars and vessels waiting, but this port is getting its fuel pretty promptly, which is all that it has to look after in the bituminous trade. The expectation of an advance in rail freights has increased the demand, but jobbers are not able to get any better supply. A great part of the coal goes from the mines to the consumer direct. While the jobbers are not discouraged, they are aware that they must wait for a change of conditions before they can do much business.

Buffalo appears to be getting an adequate supply of bituminous and more or less stocking up for winter is reported. Canada is still getting an oversupply in certain easily-reached sections and water shipments to the more remote St. Lawrence Valley are good.

The price of bituminous is based as before on the last general order, which makes the Buffalo figures $4.65 for thin-vein Allegheny Valley, all sizes; $4.45 for Pittsburgh lump; $4.20 for Pittsburgh mine-

run and $3.95 for Pittsburgh slack, all f.o.b., per net ton here. The advance in freight rates will necessitate a higher schedule as soon as it is in effect.

Anthracite—The local supply is still inadequate and does not increase. It is much smaller than it was early in the season. Nobody quite knows where it goes, but it is supposed to be taken by the Government for war purposes, possibly exported. The city consumers complain that orders given long ago are not filled. The shipping agents are not disturbed, as they find it easy to recall that after April or May it used to be a difficult matter to sell coal in any quantity till fall.

Householders who burn natural gas are pleased to see the order go out cutting off all consumers except families through the winter, though it is not easy to say what the supply will be now. The plan is to supplement the natural gas with artificial in very cold weather.

Lake shipments still run into six figures for the week, being mostly to the heads of the lakes, 50,900 tons to Chicago, 41,900 tons to Duluth or Superior, consignee's option, and 7000 tons each to Fort William and Port Arthur, total, 106,800 tons. Rates of freight are as formerly, with tonnage plenty, 60 and 65c. to Chicago, 48c. to Duluth, Fort William and Port Arthur.

DETROIT

Volume of receipts continues light in both bituminous and anthracite. Lake movement shows good average.

Bituminous—Basing calculations on present receipts, Detroit's winter coal supply is still far from being assured, in the opinion of local jobbers and wholesalers. Though weather conditions are favorable for transportation and nearly three months have elapsed during which coal should have been moving into the city in large volume, shipments much of the time have been disappointingly small and especially so during June, when receipts have scarcely equaled 50 per cent. of what dealers say should be their normal volume. With many of Detroit's great manufacturing establishments working at capacity or striving to increase production of munitions beyond normal capacity, the demand for steam coal continues active and steady, absorbing shipments as speedily as they are available. Free coal on tracks is comparatively unknown in the local market. Efforts of large consumers to put aside a reserve to aid in satisfying winter requirements have been only partly successful, owing to the necessity of satisfying needs for current consumption. Mine-run constitutes the larger part of the bituminous receipts, though slack and other sizes are arriving in small quantities. Domestic bituminous is not plentiful, dealers say.

Anthracite—Uncertainty concerning Detroit's anthracite supply is not yet relieved. The daily shipments received range around 30 or 35 cars, and few of the household consumers who are clamoring for supplies have been able, so far, to obtain hard coal. As there is virtually no coke and the market is denied smokeless coal, anxiety is increasing.

Lake Trade—Shipments of coal over lake routes have shown a moderate degree of improvement during the last week. Daily receipts at loading docks have been heavier. The movement for June is expected to exceed 3,000,000 tons.

COLUMBUS

The coal trade is firm in every particular. Demand for domestic, steam and lake tonnage is strong. The output is curtailed by car shortage in many mining districts.

Some car shortage is reported from certain mining districts, notably from eastern Ohio, which is curtailing the Ohio output. On the Hicken Valley and Toledo & Ohio Central the car supply was fair and consequently good production was reported. On the whole, however, production is falling behind anticipated figures and every effort is being made to speed up. The tone of the trade is generally satisfactory and indications point to a strong demand for the rest of the year.

The domestic trade is probably the strongest feature of the Ohio market. Retailers are anxious to buy both for present and deferred shipment. Consumers are now rushing their orders in order to avoid the higher retail prices which will prevail after the increase in freight rates take effect, June 25. The new rates will mean an advance from 20 to 35c. on the ton. Retail stocks are not large, and many are operating their yards from a hand-to-mouth basis. Pocahontas is quite scarce, as none mined east of Welsh is being shipped in this direction. There is still some West Virginia splints being sold, but the quantity is being reduced. Consumers are compelled to depend on Hocking Valley grades for their supply. Retail prices are firm at the Government levels, but an advance will be announced soon.

The steam business is active in every particular. Buying by both the larger and smaller users is reported, and many of the consumers are anxious to increase their storage stocks. Railroads are buying more than ever before as their freight movement is extra heavy. It is estimated that one-third of the output of certain fields is taken for railroad consumption. Another incentive has been the necessary advances to take care of increased rates, which will especially affect large users.

The lake trade is still active in every way. Many of the larger operations are now using their entire output for lake shipment. This necessarily reduces the available stocks for steam and domestic use. The vessel movement is generally good and a considerable tonnage is going to the Northwest. On the whole, however, shipments are behind the schedule, principally because of the late opening of navigation.

CINCINNATI

Business is settling down to a steady volume of deliveries, both local and for the lakes, limited only by the ability of the railroads to handle the coal.

With the weather definitely settled down to the summer, disposing of domestic consumption for heating purposes, the coal trade is getting into the harness for the delivery of the biggest volume of summer sales in its history. The Northwest movement via the Lake ports promises to assume unprecedented proportions, industrial consumption in that section naturally being on a par with the large consumption elsewhere, which is the outstanding reason for the present enormous demand for fuel. At the same time, enough coal is being delivered to local dealers to enable them to make some deliveries against the orders of their domestic customers, who are endeavoring to store coal for winter consumption. Industries in this section are being well taken care of as to immediate requirements, their chief concern still being the matter of their winter's supply, in view of the difficulty of storing anything like an adequate amount. Both the present limited supply of coal and the fact that a supply for any extended period would require enormous storage facilities or yard space seem to operate against much success in preparing for winter consumption; but every effort is being made in this direction, as both the trade and industrial consumers realize that every ton stored now will to that extent relieve the inevitable emergency of the winter.

LOUISVILLE

Demand considerable in excess of supplies, with no surplus stocks being laid up by jobbers or retailers. Active local demand for eastern Kentucky coal is being filled with western.

Anticipating a sharp advance in coal prices due to increased freight rates, consumers have been placing heavy orders for domestic coal, the demand being so keen that most of the local retail yards are empty, and the dealers are delivering direct from the cars. There is a shortage of teams, drivers and trucks, and this is holding back delivery somewhat.

The local branch of the fuel administration has requested the residents to go ahead and accept western Kentucky coal, instead of awaiting deliveries of eastern Kentucky stock, which is very indefinite. Many consumers are opposed to the lower grade western coal, but as the eastern Kentucky grades are moving to the by-products plants, the cotton mills and into other zones largely, practically no eastern Kentucky coal is to be had on this market. In view of the fact that western can be readily obtained the Fuel Administration is pushing immediate stocking on this grade, at the same time calling attention to the fact that the needs of the Government plant at Nashville this winter will be so heavy that there will be a big increase in the demand for western Kentucky. As a result stocking has received impetus. There has not been any particular change in the production situation in either section of the state. The car supply is holding up much better, but labor continues scarce and hard to secure, and men who went into other lines are drifting back slowly.

Eastern Kentucky mining companies have been endeavoring to buy all of the coal mined in that district that they can secure in order to take care of Louisville consumers, and the local jobbers and retailers are making every effort to obtain supplies, with the result that not even the small mines are having any trouble whatever in disposing of all of the coal they can produce.

BIRMINGHAM

Marked activity in domestic distribution. Steam demand continues at the maximum. Supply of both grades much below requirements. Little improvement noted in production.

The records for the month of June will show an appreciable gain over the month of May in domestic coal stored. The Fuel Administration has issued practically double the number of permits for car-lot shipments as compared with the same period in May. Doubtless the anticipated increase of freight rates was responsible in a measure for the increased orders. Distributors are experiencing a strong demand. Receipts continue light and unsatisfactory, due to the hampered production.

The need for an increased supply of steam coal is imperative in this market. The demand has not slackened in the least while on the other hand production is not up to the output which was being obtained a month or more ago. Industries classified as non-essential are receiving an irregular and inadequate supply. The Southern Ry. is taking 51 per cent. of the output of operations which it serves.

The Gulf States Steel Co. assumed charge of the operations of Sayre mines in the western part of Jefferson County, July 1, having purchased this property several months ago. The mines and coke ovens at this operation have been under lease to the Sloss-Sheffield Steel and Iron Co. for the past several years, the agreement covering the operation of the properties expiring June 30.

Coke

CONNELLSVILLE

Furnace coke contracts renewed. Occasional lots of free coke. No price changes in prospect.

With only one notable exception, such few contracts for blast furnace coke as expire June 30 have been renewed between the same parties. The contracts as a rule were at the Government limit, and all new contracts are of course on that basis. The one important exception was the coke that has been going to the Youngstown Sheet and Tube Co., which is building 102 additional byproduct coke ovens, to be put in operation about Aug. 1, releasing between 15,000 and 20,000 tons a month. This coke, when available, probably about Aug. 1, has been sold to other consumers at the Government limit.

In the case of foundry coke quite a number of contracts expire and quite a number of these have not been renewed, operators seeing a good market from week to week for their foundry coke, and some of them therefore prefer not to tie up with individual foundry interests, whose actual consuming rate, in these times, may prove more or less uncertain.

The business of the coke brokers has practically disappeared, first because nearly all the furnaces that are in need of extra coke keep representatives of their own traveling through the region to pick up coke, so that they get it before brokers have an opportunity to hear of it, and second, because brokers cannot charge a commission unless they secure it from sellers, and sellers have no occasion to offer a commission. There is a fair volume of business done in spot coke from week to week in direct transactions. The market remains quotable as formerly: Furnace, $6; foundry, 72-hour selected, $7; crushed, over 1 in., $7.30 per net ton at ovens. The War Industries Board has fixed iron and steel prices for the third quarter of the year at the schedule expiring June 30, with an advance of 45c. a ton in iron ore, by reason of the freight-rate advance. Coke prices are fixed by the Fuel Administration, but there is no likelihood of any change until fundamental conditions change, and with pig-iron prices set for another three months there is not the least likelihood of any change in coke prices in the near future.

The Connellsville "Courier" reports production in the Connellsville and Lower Connellsville region in the week ended June 15 at 342,970 tons, an increase of 1950 tons. Production has been at substantially the same level for eight weeks.

Buffalo—The demand is about as before, but reports from Canada say that it is not so heavy as formerly. The regulation oven price of $7 for foundry and $6 for fur-

nace holds, with $2 freight added, but next to none sells in the open market. Canada pays no duty, but pays 7½ per cent. of the mine price as Canadian war tax. Iron ore receipts by lake continue, the amount for the week being 262,664 gross tons. Reports from Ohio predict that June will be a record month on this movement. Cars are not plenty enough to move the ore promptly that is consigned to outside points.

Middle Western

GENERAL REVIEW

The supply of cars seems to be sufficient to take care of all the coal that can be produced. Outlook encouraging.

Reports from all the producing centers in the Middle West seem to indicate that the railroads are at last able to furnish a sufficient supply of cars to handle all the coal that can be produced. In fact the Illinois Central is reported to have had far more cars available for loading than were needed the past week. This is unusual. In the preceding several months this line has been charged with being one of the principal offenders. During the past week production reached the highest level heretofore known, a direct result of increased car supply, and if the miners could now be induced to work full time no doubt production would be further increased. Regardless of the fact that more coal was mined and shipped last week than in any previous week, the demand for prompt shipment still is a source of worry to the sales managers throughout the country. The householders are buying as heavily as though it were winter, a direct result of the activities of the Fuel Administration's "Buy Your Coal Now" campaign. Another factor that has caused heavy buying is the putting into effect on the 25th inst. of an advance freight rate, ranging from 15 to 35c. per ton higher than the present rate.

Steam users, including the railroads, have not as yet had an opportunity to store much coal. This has caused more or less worry among some consumers, who fear that they will not be able to get some stock ahead prior to the fall and winter months, and that they will be caught as they were last year, without coal. Operators in a position to know say that with the present flow of coal to the dealers for another month or six weeks domestic users will be fairly taken care of, and they then will be in a position to give steam coal substantially heavier shipments.

CHICAGO

The demand for domestic sizes continues to be in excess of supply.

The response made by the householders to the request that they buy coal early has produced satisfactory results to date. Never before in the memory of the oldest dealer has there been so insistent a clamor for coal as now. The demand is so heavy, in fact, that dealers are far behind and have not been able to accumulate any surplus stock.

The market on screenings is still without any strong indications, and considerable fine coal has been moved through jobbers at 15c. per ton off the Government price; not, however, to the extent that any material reduction resulted to the ultimate user.

There is no change in the hard-coal situation, householders having placed their orders with the dealers, who in turn have placed the orders with shippers. All wait impatiently for some indication that the coal will be forthcoming at a later date. So far the receipts have not met with earlier expectations.

Quotations in the Chicago market are as follows, per net ton f. o. b. at mines:

	Williamson and Franklin	Saline and Harrisburg	Fulton and Peoria	Springfield	Carterville	Grundy, La-Salle, Bureau and Will.
Steam lump	$2.55@2.70	$2.55@2.70	$2.95@3.10	$2.55@2.70	$2.55@2.70	$3.25@3.40
Domestic lump	2.55@2.70	2.55@2.70	2.95@3.10	2.55@2.70	2.55@2.70	3.25@3.40

MILWAUKEE

Anthracite price schedule not yet received. Deliveries now being made by all dock yards and dealers.

The State fuel office is at a loss to understand why dock prices at Milwaukee on anthracite coal have not been formulated. It is understood that they were dispatched from Washington, but thus far they have not shown up. Deliveries of hard coal are in full swing, however, and the situation is more satisfactory in consequence.

Since last week's report an additional cargo of 8500 tons of anthracite has been docked, making the total receipts of hard coal since the opening of navigation 144,735 tons. A great deal of this is now in the bins of consumers. During the same period 736,683 tons of soft coal was received.

Every effort is being made to increase the use of soft coal. Coal dealers throughout the state have been notified that threshers should be supplied with mine-run coal or grades of steam coal other than the domestic sizes of bituminous coal which they have been in the habit of using in the past. Manufacturing concerns which have been restricted to 50 per cent. of their normal supply of coal are endeavoring to secure more by promising to use inferior grades than they formerly used, but thus far have met with refusal. Some firms which have stored more than the regulation amount will also be held to the rule.

ST. LOUIS

Fairly active market on Standard grades the first time in many weeks previous to the 25th. Lagging market follows. Car supply showing up poorly. Screening market rather weak and good demand for domestic sizes from high-grade fields. Local retail buying normal. Labor shortage growing acute. No Eastern coals and light tonnage of Arkansas.

The week previous to June 25 the local market was fairly active. Not only because the freight rate advanced 25 per cent. on the 25th, but for the past week there has been an unusually heavy car shortage. This followed a few weeks of car supply that was normal, and large buyers in an endeavor to force the market laid off buying so that when the car shortage struck them they were caught short. This is especially true of the mine-run and screened sizes. Screenings continue weak from the Standard field, going at about $1.25 to $1.35.

The recent activity did not stimulate the Standard market to any great extent as regards price; 2-in. lump went around $2.20, with mine-run at about $2. In some sections of the Standard field the past week mines have been idle on account of no business, contrary to operating reports. In the high-grade fields there has been a continued effort on the part of the operators to increase production by using car supply, but the labor shortage there continues, and the falling off of the equipment the past week showed a tonnage loss.

In the Mt. Olive field the demand still continues to meet with the production. The mines are working perhaps better than in the other fields, and there is not the decrease in the tonnage noticeable here on account of labor shortage as in other sections.

Following the large amount of coal stored during the low freight rate the expected lull in business in the Standard field was natural and the end of the present week will see some extremely low prices. The only ray of hope for the Standard field was a tip from Washington that the Government had ruled against the railroads having any more Williamson or Franklin County coal for locomotive purposes, with a few modifications. This is going to throw a vast tonnage of high-grade coal into the industrial and domestic market, where it rightfully belongs. It has been almost a crime that the railroads should grab the best coal produced in the State of Illinois while the City of Chicago and other large cities were in dire need of this low-volatile fuel, when the railroads could just as conveniently, and almost as economically, use the high volatile fuels.

This will force the railroads to take a large tonnage of their coal from the Standard and Mt. Olive fields. This will give the men steady work on account of no orders, and it will retain the men in the Standard mines that are now leaving to seek employment in other fields that work steadier, or to go to big industrial plants in the cities. It will strengthen the Standard market and force the Government maximum price on these coals which for several months now have been selling below that price.

The domestic demand locally is light. This is because orders are many weeks behind and retailers are having trouble effecting deliveries. Labor is short and independent, and an effort has been made by the retailers' association to have the Government take some action compelling employees of coal companies to work at least five days a week as against three and four at the present time.

Coke, which will largely supplant anthracite coal in this market, has been selling at 60c. under the Government price, but effective June 25 it went to the Government price, which with the increased freight rate will increase the price of coke to the domestic consumers about 95c. a ton.

The Chamber of Commerce in St. Louis prepared the latter part of the week to put up a vigorous fight at Washington for a specified tonnage of anthracite coal for certain places in St. Louis that must have anthracite coal or suspend operations, and also for a number of homes in the city that are equipped to burn nothing but anthracite and which cannot secure other equipment for many months to come.

Coöperating with the Chamber of Commerce will be the Coal Service Bureau of St. Louis and the Missouri State Retail Coal Merchants' Association, as well as the Manufacturers' Association and other organizations of similar nature.

The prevailing market is, per net ton f.o.b. mines:

	Williamson and Franklin County	Mt. Olive and Staunton	Standard
6-in. lump	$2.55@2.70	$2.55@2.70	$2.40@2.70
3x6-in. egg	2.55@2.70	2.55@2.70	2.35@2.55

Williamson and Franklin County rate is $1.10; Duquoin field, $1; Standard and Mt. Olive fields, 95c.

SEATTLE

Coal situation not promising, public not buying and mines operating only part of time. Mine convention asks national fuel head to investigate matter.

At the twelfth annual meeting of District No. 10 of the United Mine Workers of America, resolutions were passed by the representatives of the 32 state local unions, which have a membership of 5000, asking the national fuel administrator to make a thorough investigation of the coal situation in this state. It is pointed out that in April, when the mines of Washington began to slow down their production, between 800 and 1000 skilled workmen left the mines to obtain steady employment. Many of the mines are still operating only part time. If the coal business should pick up within the next few months the mines could not be worked to full capacity on account of the labor loss. The mines of Issaquah, Newcastle, the Cumberland district, some Pierce County districts and the southwestern Washington district, all of which produce mainly domestic coal, have of recent months been operating only one to three days a week. The public is not buying coal and nothing seems able to stir them to a full realization that early buying is the only way to prevent a fuel famine here, though all hope that there will be enough coal to meet the demand was given up several weeks ago. Coal prices, which recently took another advance in Seattle and resulted in many demands for an investigation, will shortly take another advance, as new freight rates went into effect on June 25 and teamsters are demanding larger wages. There is a railroad car shortage ahead which is going to hamper the delivery of coal this winter in the Northwest still further. The coal situation in Washington is not promising for the coming winter.

COAL AGE

With Which is Consolidated The Colliery Engineer

McGraw-Hill Co., Inc. 10c. per copy New York, June 29, 1918

Tipple at Mine No. 3 of the Raleigh Coal & Coke Co., Raleigh, W. Va.

Erected on center line of old wooden tipple with a total shutdown of only 45 minutes.

Bring your equipment up to maximum now!

Suppose you can "get along" with the Tipple Equipment you now have.

With equipment less effective than it could be you lose profit now.

Later, when competition is again in full force, you face even greater losses.

Webster methods in coal handling mean maximum effectiveness.

Mean more uniform coal with less slack.

Mean larger profits.

Webster Equipment, now as always, means highest quality intelligently applied.

by Webster Methods

Let Webster Engineers check over your Tipple Equipment and make recommendations. Installations can be made without loss to present production.

This standard, double-drum geared hoist has 60 by 42-inch drums, two 60-inch clutches, two 80-inch post brakes, all air-operated; dial indicators, herringbone gears, flexible coupling. We have built this hoist for various mining companies in the United States, Canada and Mexico.

W-S-M
Electric Mine Hoists

The manufacture of hoists has been a specialty of this Company for many years. In our hoist construction there are combined with good and carefully selected materials an engineering and manufacturing excellence, developed under the guidance of high ideals, but tempered and made profitable by long and diversified experience.

A W-S-M Hoist is not the lowest-priced hoist you can buy. In fact it is perhaps the highest-priced hoist built. But superior service, safety, economy of operation, reliability and long life more than offset the additional first cost.

Write for Bulletin C 5, "Electric Mine Hoists."

Leaders In Coal Mining Machinery Equipment

"Results exceeded expectations and cost of gathering is much lower"

This is the substance of a report from a leading Coal Company in Indiana regarding their two 5-ton

JEFFREY

Storage Battery Locomotives

These locomotives replaced mules used for gathering. Some of the advantages of Jeffrey Storage Battery Locomotives over mule haulage are:

1. Only one man required to operate the Locomotive and handle the cars.
2. Three-ton to five-ton Locomotives are replacing from 3 to 4 mules, each.
3. Saves the cost of drivers, mule feed, harness, shoeing, etc.
4. Sanitary conditions about the mine are very much improved.

Jeffrey Storage Battery Locomotives are ruggedly built with large, durable wearing surfaces and ample mechanical strength and accessibility. They work wherever tracks are laid—right up to the face of low headings where a mule cannot go.

Write today to Dept. 12—ask for our special bulletins showing actual installations of Jeffrey Storage Battery Locomotives.

The Team That Wins

The Ideal Sectional Insulator

Note the insulated wood back. It's waterproof and damp proof. Therefore, it makes it absolutely impossible for current to leak from one section to the other when the cut-out is open.

And the cut-out—that's *bronze*. When closed it forms a *continuous* line. No flashes of sparks as with old-style wooden gaps; no burning out of armatures or blistering of wheels when a trolley wheel passes over it. No, it keeps the voltage the same throughout and thus eliminates voltage strain.

Are you interested? Most certainly you are if you have investigated the cause of excessive maintenance costs when the old-style insulators are used. Let us send you full particulars explaining a simple method to keep these costs down to a minimum and to safeguard the lives of your men in the bargain.

Write us today for full particulars.

Pure Iron For Railroad Service

The construction here illustrated embodies the last word in appliances for handling coal from cars to vessels. It is a master-work of modern engineering.

Ten thousand lineal feet of belts are employed on this Coal Pier, the largest being sixty inches in width. The decking to protect this belting is of Rust-Resisting Armco Iron.

Armco Iron was also used in a novel method for waterproofing the feeder pits. These pits are approximately forty feet wide and seventy-five feet long and are eleven feet below the tide level. A solid bin was constructed for the bottoms and sides of these pits of Armco Iron, protected on the outside by six inches of concrete. This gives an absolutely water-tight pit of enduring material.

This is the Iron That's Made to Last

The American Rolling Mill Company

MIDDLETOWN, OHIO

AMERICAN ARMCO INGOT IRON

The trade mark ARMCO carries the assurance that iron bearing that mark is manufactured by The American Rolling Mill Company with the skill, intelligence and fidelity associated with its products, and hence can be depended upon to possess in the highest degree the merit claimed for it.

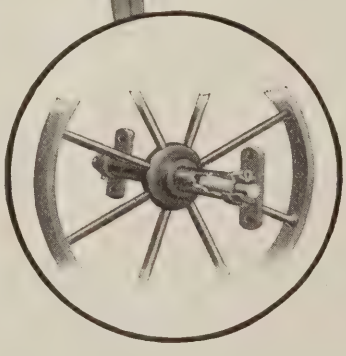
VULCAN HOISTS

Sterling

This Little Cotter Pin Means a Lot



In Sterling Wheelbarrows, just as in everything else, it's the little things that count.

This cotter pin is a small detail. Its value in Sterling construction is great.

It is used at both ends of the axle, passing through the malleable brackets and axle and holding the latter securely in place. It is impossible for a Sterling axle to turn with the hub.

Contrast this with the ordinary bolt axle construction—no nuts to work loose and come off—no tightening up until the frame binds the hub. Just a nice fit—no more, no less.

"Cheap" wheelbarrows are expensive at any price. Buy Sterlings for economy.

Ten Other Sterling Features

Malleable Wheel Guard
Broad, Flat Leg Bearings
Self Lubricating Wheels
Cold Rolled Steel Shafts
Patented Handle Clamps
Malleable Wheel Supports
Tested Clear Maple Handles
Riveted Leg Braces
Balanced Load
All Parts Interchangeable

PLACE YOUR ORDER *NOW!*

THE MANIERRE BOX CAR LOADER

Shown here is a 24" Portable Belt Loader

that has been in active and successful service for the Ft. William Coal & Dock Company, at Ft. William, Canada, since October, 1913. It is a double acting Loader, mounted on M. B. C. car for standard gauge track. A chute is equipped with balanced gate which we furnish with or without lip screen and hopper.

This type of loader is especially designed for handling "run of pile" Coal or Coke and is for loading coal beyond the reach of the usual reclaiming machinery. This particular machine was designed and mounted for its local duty. We build a standard machine of this type of wide application.

Our strong point is that we can solve problems and meet any sort of unusual conditions with our machine.

We are prepared to do our part in filling orders promptly for any Standard Loader because we have looked ahead and have a stock of electric motors, chutes and loaders ready for immediate shipment.

Don't hold your order. If you want a Manierre Box-Car Loader this season, GET IT NOW.

Box-Cars can be used and great savings realized with a Manierre Box-Car Loader. It pays for itself fast, if kept busy.

The Government gives this machine priority.

A Real Service

IT HAS been said that the adaptation of wire rope to coal mining was one of the greatest single improvements in the industry. Without wire rope it would be impossible to raise the great loads of coal to the surface or to lift the huge water buckets with rapidity, steadiness and safety.

We of the Texas Company can say in truth that we have brought something of value to the coal mining industry, by inventing and developing TEXACO CRATER COMPOUND and proving out its service in increasing the useful life of wire rope.

This product has been the means of preserving thousands upon thousands of feet of hoist ropes and other ropes, saving them from wear and from deterioration by chemically contaminated waters. This remarkable lubricant has frequently doubled the life of severely exposed wire rope, not only in coal mines but on ropes used for drilling oil wells, on steam shovels, on dredges and elsewhere.

Thus, we can readily say that we have made an important contribution not only to the coal mining industry but to others as well.

We have written up part of the story of TEXACO CRATER COMPOUND in a 48-page illustrated book which is yours for the asking. Just ask us to send you "Wire Rope Lubrication." A post card will bring it.

KEYSTONE GREASE Increases Car Capacity

THERE'S a big difference between *lubricating* mine car wheels —and *lubricating them properly*. Most any lubricant is better than none at all. But a lubricant which enables mine locomotives and mules to pull *more cars* at *less* expense is something worthy of the serious consideration of every mine operator.

When properly packed in mine car wheels of good condition, one application of **Keystone Grease** affords this type of lubrication—without attention—for from three to six months.

KEYSTONE GREASE

is an important factor in increasing mine efficiency and decreasing fire risk in the leading coal fields of America.

It lengthens the life of roller bearings, keeps equipment from the scrap pile—saves time, labor and money. Its density is unaffected by temperature changes, water, or outside chemical attacks. And there is no waste of the lubricant itself as when oil is used.

Keystone Grease No. 119, Medium is scientifically suited for Hyatt Roller Bearing Mine Car Wheels—Keystone Grease No. 2 should be used for Solid Roller Bearing Wheels, and Keystone Grease No. 119 is suitable for all other types.

Let one of our experienced lubrication engineers call and arrange for a trial installation in *your mine* at *our risk*.

A Tight Bond with "Gunite"

Showing the "Gunite" Picked Down.

How many mine stoppings are made practically useless because the poisonous gases leak around the stopping? No doubt you have encountered such experience in your own mines.

But with the CEMENT-GUN, this evil is gone forever. Not only does the cement-sand product, **"Gunite,"** make the stopping air-tight, but you can *seal the passage* as far back as necessary *to prevent the gases working around.*

The same use applies in stopping roof slacking. **"Gunite"** keeps out the air and therefore slacking is prevented.

Another use is protection of steelwork and timbering, concrete and masonry. **"Gunite"** builds up a lining that fills every crevice, clings with a bond like steel and places an absolute barrier against weathering.

There are so many practical uses, both in the mine and above ground, that you should read the Book of Bulletins to grasp them all. Regret the time spent? *Never.* **Just drop us a card today.** No obligations.

This Pump "Stays Put"

It's an AUSTIN

"The Pump the Mine Man Needs"

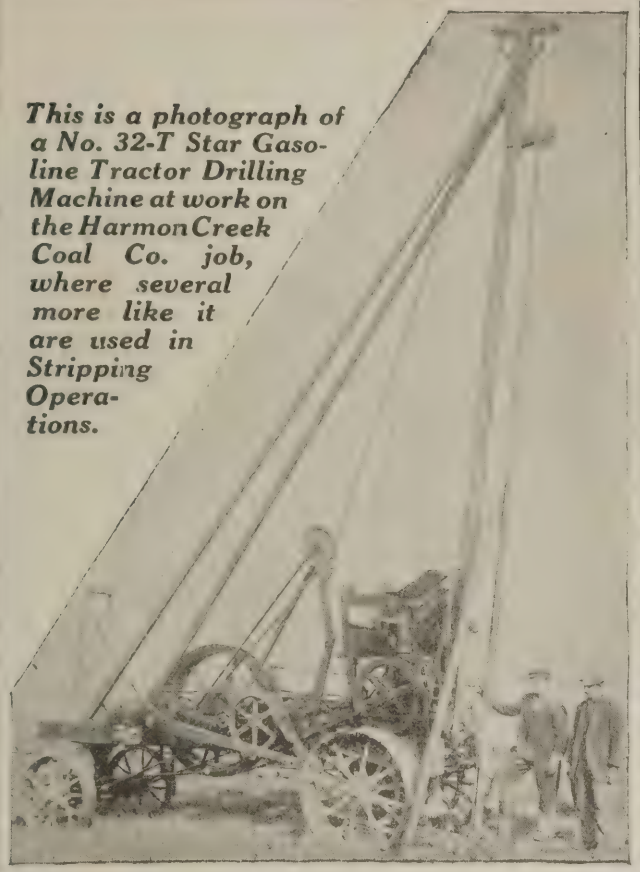
ONCE you put this pump in place in the mine, you don't have to pull it out again to rebabbitt the bearings or to clean the valves.

The bearings are removable—the valves can be reached for cleaning by simply removing one nut—all bearings are adjustable without taking the pump apart.

Water box is of special patented construction and motor spur is of the flywheel type. Thus both the discharge line and the motor are fully protected from shocks.

Capacities

30 to 200 Gallons per minute.
Sizes up to 100 gallons per minute carried in stock.



Send for illustrated bulletin.

The Dravo Contracting Company

Engineering Works Department

Diamond Bank Building, Pittsburgh, Pa.

Philadelphia Cleveland Indianapolis

This is a photograph of a No. 32-T Star Gasoline Tractor Drilling Machine at work on the Harmon Creek Coal Co. job, where several more like it are used in Stripping Operations.

Mr. Coal Mine Operator

Do you use a steam shovel for stripping?

Then You Need a Star Drilling Machine for Drilling Blast Holes To Increase the Efficiency of Your Shovel.

Do you want to test out an undeveloped field?

Then Do Your Prospecting with a Star Machine.

Do you require ventilation holes?

Then Drill Them with a Star.

Whatever your drilling problem, through shell rock, trap rock, limestone, there is a Star Machine to handle it.

Made with Gasoline Engine, Steam or Electric Motor power. Tractor or Non-Tractor. Any size hole, any depth.

The constant repeat orders represent our strongest argument for durable construction, efficiency, economy in operation and general satisfaction.

Learn more about the Star Drill.
Catalog sent on request.

Akron, Ohio, U. S. A.

Erie Revolving Shovels

Photo shows one of FIFTEEN ERIE Shovels bought by P. & R. Coal & Iron Co., Pottsville, Pa., after making careful tests of steam shovels.

Do You KNOW Which Steam Shovel to Buy?

Profit by this experience

If you are in doubt as to the right steam shovel to buy, for stripping and loading—here is some experience which may be helpful to you:

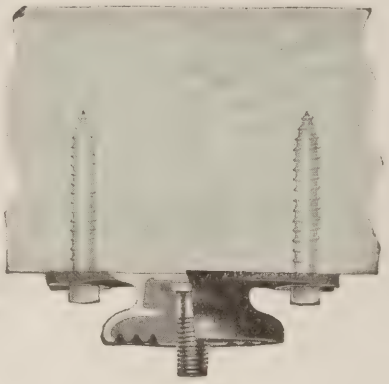
Tested one Erie—bought 15!

The Philadelphia & Reading Coal & Iron Co. are experienced users of steam shovels. They owned about 20 shovels of different makes, when they bought their first ERIE, late in 1916.

Since that first ERIE, they have added 14 *more* ERIE Shovels to their equipment.

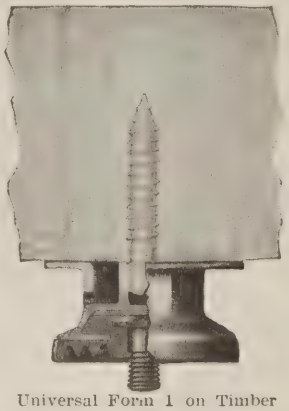
Bigger output

They have found that the quick movements of the ERIE, and the simple control by three levers, result in more output than they had been accustomed to from steam shovels of equa size.



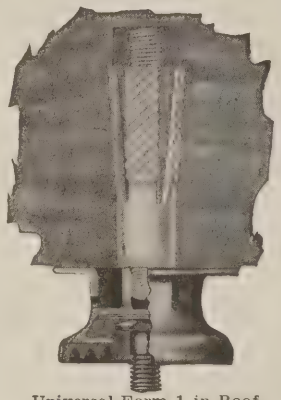
Reliable service

They have found that the ERIE Shovel works steadily in the hardest digging, because it is built far stronger than the usual standard of steam shovel construction.



We will be glad to send you our Bulletin "A." It tells you what the ERIE Shovel can do on your work. Write for a copy.

Ball Engine Co., Erie, Pa.

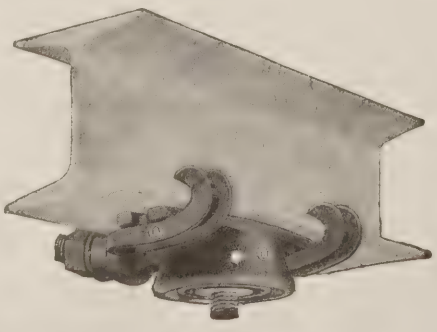


O-B PRODUCTS

Type H-3 on Timber

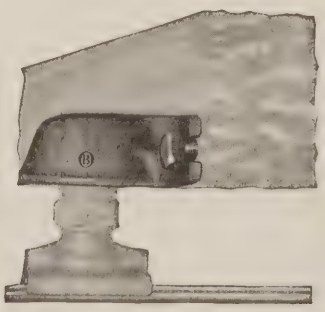
Universal Form 1 on Timber

Universal Form 1 in Roof



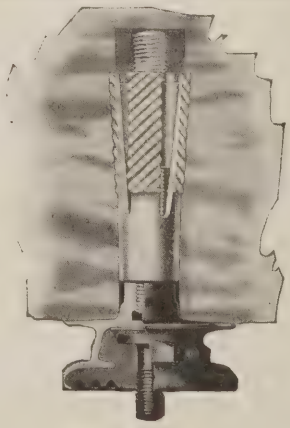
O-B TROLLEY HANGERS SUIT EVERY MINE

Perhaps you have noticed—most mining men have—how O-B Hangers "fit" in the mine in every sense of the word. It is the logical result of applied experience and knowledge.

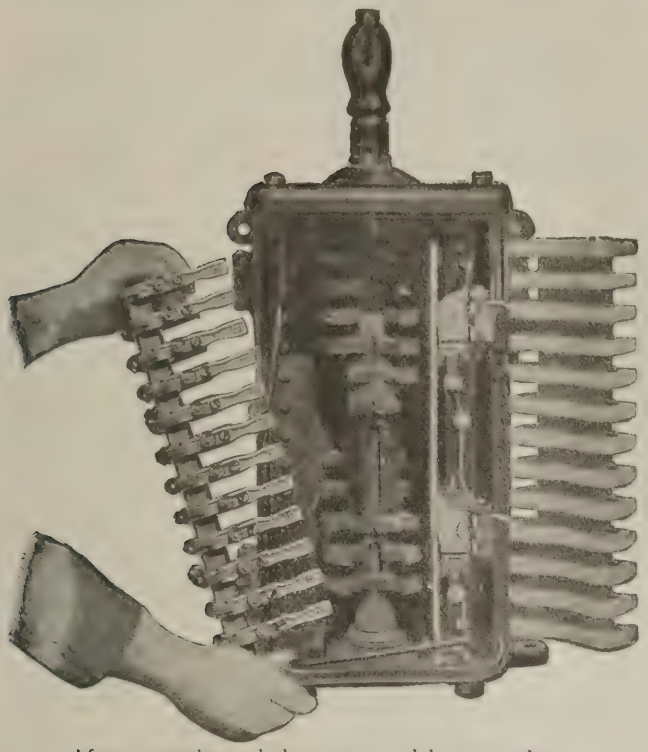


See Catalog No. 16 *and Supplement No.* 1 *for complete listing of the many different types. One of them is the right one for your mine.*

The Ohio Brass Company, Mansfield, Ohio



New York Philadelphia Pittsburgh Charleston, W. Va. Chicago San Francisco Los Angeles



Type H-2 installed on steel beam with O-B I-Beam Clamp

Type P on side of Timber

Type K-3 in Roof

After removing a bolt at top and bottom, the contact fingers may be removed.

Easy to Get At

Just Remove Two Bolts

and you can lift out the contact fingers as shown in the illustration. This is a C-H feature that those experienced in crane and hoist work consider of great importance.

DRUM CONTROLLERS

For Crane and Hoist Service

because of their superior rugged construction provide the most precise operation. Each speed point can be distinctly felt by the operator—yet the operation is smooth. They are made in D.C. and A.C. types.

The straight line non-stubbing fingers, first employed on Cutler-Hammer Controllers, are mounted on a square metal shaft. This can be removed in one piece as shown above.

Ask for Booklet containing Drum Controller Bulletins. The office nearest you has a stock of these Booklets as well as Booklets describing C-H Battery Charging Apparatus.

Back of this man and his motor lies your mine and all its equipment Don't let a faulty Bearing hold up your mining operations

SKF
BALL BEARINGS

The mine owner is being pressed by the need for greater fuel production.

The dependability of mining machinery, next to the operators, is the controlling factor of output.

Mining machinery SKF equipped has the staying quality needed for unusual service.

SKF BALL BEARING CO.

Hartford 416 Conn.

HERE IS THE REASON WHY *This Construction*

Why over 120,000 Edison Electric Safety Mine Lamps are in use today.

Why over 1000 Mines are using Edison Mine Lamps almost exclusively.

Why every Edison Mine Lamp is still in service, giving good service.

Why Edison Mine Lamps have never been replaced by any other electric mine lamp.

Why its record is one of unqualified success.

is found only in the Edison Electric Safety Mine Lamp.

This is the steel and iron construction of the famous Edison Nickel-Iron-Alkaline Storage Battery.

This shows the steel positive tube, banded with steel rings; the steel negative pocket, the steel connectors and poles; and the steel container of the cell itself, as well as the steel carrying case.

Another distinctive feature, found only in Edison Batteries, is that steel parts are submerged in an alkaline solution, which is a **preservative** of the steel.

The Edison is the only storage battery with any iron or steel in its construction or elements.

This construction explains the great strength and long life of the Edison Mine Lamp.

Let us tell you many other interesting features about the Edison Mine Lamp. Ask for Bulletin 300-C.

Let Us Help You Serve Effectively

Service is vitally necessary in business today that we may pull together to accomplish our common aim.

The General Electric Company has located industrial power experts at all large cities in this country to serve industry's electrical requirements. For instance, experienced textile mill electrical engineers will be found in all textile centers. Among other industries so served are the iron and steel, coal and metal mining, cement, clay and glass, lumber and woodworking, grain and sugar, canning, packing and refrigeration, shoes and rubber, paper and wood pulp, tobacco and cigars, chemicals and gas, and the construction and shipbuilding.

These experts are prepared to cooperate with industrial engineering firms to show the best way to drive a machine or a factory to get maximum production of highest quality at minimum power cost.

Back of these experts is the experience gained in supplying much of the electric power equipment now used in American industry and a corps of scientists with research facilities for pioneer work.

Call on us to help perfect your service to American business.

Can You Use Some Extra Money?

Of course you can.

We will gladly tell you how to make this extra money, if you are likely to be interested in acting as our special representative for the sale of the COAL MINERS' POCKETBOOK.

Other representatives are successfully selling this book and you can do likewise without any difficulty.

Wherever coal is mined—there you will find men who need the COAL MINERS' POCKETBOOK.

It is the *old reliable* in the coal mining field.

We need the spare time of someone to show these men this valuable book. It sells on sight.

That is why we want you to represent us on a liberal commission basis, with the understanding that you will not be required to make any investment or be under any obligation if you will fill out the coupon.

The compensation is liberal, and the experience valuable.

Will you act as our representative, and make some extra money?

ADVERTISING RATES

Ads Set in Uniform Style

(Solid, in one paragraph, without display.)

THREE CENTS A WORD, minimum charge 50 cents an insertion, payable in advance, less 10 per cent if one payment is made in advance for four continuous insertions—for advertisements under:

Positions Wanted	Vacation Work Wanted
Evening Work Wanted	Salesman Wants Connections

FIVE CENTS A WORD, minimum charge $1.50 an insertion, for advertisement under:

Agencies Wanted	Positions Vacant
Agents Wanted	Partner Wanted
Business Opportunities	Representations Wanted
Desk Room for Rent	Salesmen Wanted
Educational	Patents for Sale
Employment Agencies	Plants for Sale
Desk Room Wanted	Sub-Contracts Wanted
Foreign Business	Work Wanted

Miscellaneous for Sale, for Rent or Want Ads.

THIRTY CENTS A LINE, minimum five lines, for all undisplayed advertisements set with a paragraph for each item or tabulated.

THREE DOLLARS AND SIXTY CENTS AN INCH for advertisements for bids (Official Proposals).

Ads Set in Display Type

(Individual space, within border rules.)

Space for these advertisements is sold by the inch. Each page contains 27 inches. The rate per inch is based on the *total* number of inches to be used—that is, the number of inches the advertisement is to occupy multiplied by the number of insertions it is to receive. For instance, a 2-inch advertisement in 2 issues earns the 4-inch rate of $2.90 an inch. A 1-inch space in 4 issues, or a 4-inch space in one issue, also earn the 4-inch rate.

SCHEDULE OF RATES

1 to 3 in., $3.00 an in.	15 to 26 in., $2.70 an in.
4 to 7 in., 2.90 an in.	27 to 49 in., 2.60 an in.
8 to 14 in., 2.80 an in.	50 to 99 in., 2.55 an in.

Rates for larger space furnished on request.

INFORMATION

ALLOW FIVE WORDS for the address, if replies are to a box number in care of any of our offices. There is no extra charge for forwarding replies.

IN REPLYING TO ADS. do not enclose original testimonials or anything that you may want returned. State your experience and qualifications in as concise and neat a manner as possible and enclose copies of your testimonials.

BE CAREFUL TO PUT ON ENVELOPE, when answering any "blind," ad, the box number in the ad, the name of the paper, and also the local address of office to which reply is sent:

36th St., at 10th Ave.,	New York
1570 Old Colony Bldg.,	Chicago
657 Leader-News Bldg.,	Cleveland
935 Real Estate Trust Bldg.,	Philadelphia
501 Ria to Bldg.,	San Francisco

WHEN ADVERTISING MACHINERY, use your own name and address—or a local address of some kind—so that the readers can wire direct and get quick replies. We advise also that you state in your advertisement the present location of plant that is offered for sale, or point of delivery provided you are in the market for equipment.

TO SIGN YOUR NAME and address to your advertisement begets the confidence of the reader and facilitate receiving replies. You can however, obviate delay in receiving answers by signing your ad. only with initials (your own or others), care of your home, your office or a post-office box number in your city.

For quick and satisfactory results tell the reader everything that he will want to know

POSITIONS VACANT

FIRST-Class electrician. One capable of taking care of machinery. Operation production 25,000 tons per month. Furnish recommendations and experience, also salary expected. P-119, Coal Age, Phila.

MINING engineer. One capable of taking care of construction and mining work. Operation production 25,000 tons per month. P-116, Coal Age, Phila.

SUPPLY clerk. One capable of taking care of correspondence and checking in and checking out supplies. Operation production 25,000 tons per month. P-117, Coal Age, Phila.

ASSISTANT mine foreman, with first or second-class papers. One capable of taking care of a section of Machine Mine. P-118, Coal Age, Phila.

MINE foreman wanted for a large coal company in West Virginia having every favorable condition. P-140, Coal Age.

MINE foreman for low coal operation, West Virginia, near large town. Want hustler capable of handling men and mining machinery. Good salary and tonnage bonus for man who can get results. State age, experience, references. Write P-141, Coal Age, Phila.

WEST Virginia licensed mine foreman wanted to take charge of new development. Address M. M. Co., 1020 First National Bank Bldg., Huntington, W. Va.

AN experienced transitman wanted for mine and outside surveying. Permanent. Single man preferred. Give age, references and salary wanted. Apply Chief Engineer, Box 42, Dunlap, Tenn.

PRACTICAL mine electrician wanted as traveling inspector by prominent company manufacturing electric coal mining machinery. We require coal mining experience with knowledge of machines and locomotives. Permanent position with good salary assured the right man. Address stating age, experience and references. P-139, Coal Age, Chicago.

TRANSITMAN, married, above draft age, for work with a large bituminous corporation in western Pennsylvania. Advise experience and salary desired. Box 511, Indiana, Pennsylvania.

POSITIONS WANTED

MINING engineer; 5 years' experience, desires change. W. Va. or Kentucky. Married. PW-127, Coal Age, Cleveland.

MINING engineer wants a position in the engineering department of a coal mining company. 12 years service in U. S. A. and abroad. Single, not in draft. Speaks foreign languages. At present employed. Would like to give the present employers at least 15 days' notice. PW-128, Coal Age, Philadelphia.

MECHANICAL and power engineer, technical graduate, with wide and varied experience in the design and construction of power, hauling, pumping, ventilating plants and general coal mining equipment, seeks an opening. PW-131, Coal Age, Philadelphia.

MAP draftsman, first-class. Coal mine or land map draftsman and general office work, more than twenty years' experience, references. Not in draft. American. State salary willing to pay. PW-133, Coal Age, Philadelphia.

SUPERINTENDENT
OF MINES OR CHIEF ENGINEER

Successful, up-to-date, experienced efficient superintendent or engineer open for position. Present superintendent of mines. Must give 3 or 4 weeks' notice.

PW 136—Coal Age
935 Real Est. Trust Bldg., Philadelphia, Pa.

POSITIONS WANTED

CHIEF electrician and mechanic, expert on power-plants and general coal mining equipments, of all systems, methods, moderns efficiency, companies needing qualified man. PW-111, Coal Age,

MINING engineer desires position. 1911 graduate, married, at present carrying the work of twelve bituminous properties. PW-130, Coal Age.

CHIEF clerk, open for position July 1st as auditor or paymaster for company having several mines; capable of systematizing; 15 years in coal business; can refer to present and past employers; married; above draft age. What have you in an executive position where there is chance for advancement? PW-135, Coal Age, Philadelphia.

SUPERINTENDENT—Have 15 years' experience as inside foreman, outside superintendent and engineer; 1 year's experience in stripping. Available Juy 1. Age, 36. Married. PW-137, Coal Age, Cleveland.

MINING engineer now general manager willing to change, age forty-three, twenty years' experience, coal mining, designing, surveying, etc., can handle men, is available immediately. PW-138, Coal Age, Phila.

FOR SALE

Developed and Undeveloped Coal Mines

Going Mines ready for immediate operation. Located on railroads and rivers. Fifteen in W. Va., ten in Va., fifteen in Penn., twenty in Ky., and Tenn. Advise of what you want and you will be suited. FS-84, Coal Age, Phila.

Correspondents Wanted

We are interested in securing correspondents in mining centers who can send us news in their spare time of new mines to be opened, equipment to be purchased, etc.

Write giving full details of present work to

BIG BARGAIN

COAL STORAGE PLANT

We have for sale and *immediate delivery*, the Coal Storage Plant formerly owned by the Susquehanna Coal Co., located at Old Bridge Storage Yard, about six miles from South Amboy, New Jersey.

This plant consists of seven complete units, each unit consisting of two trimmers and one reloader.

Each trimmer has a storage capacity of 15,000 tons of coal, with an overload of 25%, therefore each *unit* has a storage capacity of 30,000 tons plus an overload of 25%.

Each trimmer will unload 200 tons per hour, and material can be reloaded at same rate, at a cost of about 2½ c. per ton, each way.

This Plant can be operated as a whole, or in individual units. It was designed, built and erected by the Link-Belt Engineering Co., of Philadelphia. It is in perfect condition, and can be readily taken down and reconstructed.

We are prepared to furnish blueprints and photographs upon request.

If you are interested, communicate with us at once, and we will arrange for inspection.

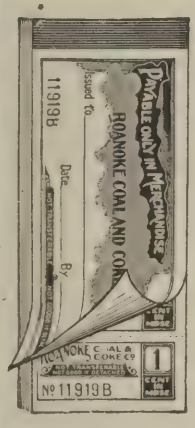
AETNA

Just off the Press

This booklet on "Lion" Brand Blasting Caps tells about their use; their composition; their strengths; their calibres; their dependable charges, and why dependable; the advantages of using strong Detonators; precautions for handling and storage, etc.

Too frequently the Dynamite—of any manufacture— is blamed when mis-fires occur, where an examination of the Detonator used would probably show that it did not explode completely, or with sufficient strength to detonate the Dynamite. These mis-fires are costly and dangerous.

Surely you want to avoid mis-fires—



"Lion" Brand Caps, charged with FULMINATE OF MERCURY, cost no more—

Then write for this free booklet (size 3½ in. x 6 in.)—read it carefully—and use "Lion" Blasing Caps or "Lion" Electric Blasting Caps.

Automatic Operation

WHAT does the term AUTOMATIC OPERATION convey to you? Does it indicate some useless adjunct intended to lighten your burdens but which only adds to your worries?

If this is your conception it is evident that you have not been advised of our methods of accomplishing

Practical Automatic Operation

It is not an impossibility to have a plant that WHOLLY meets your requirements. In fact, we have designed and supervised many such plants on a PRACTICAL COMMON SENSE BASIS which *operate* on this basis.
We are PRACTICAL specialists in AUTOMATIC OPERATIONS in HEAVY DUTY PLANTS. Our thorough knowledge of modern conditions and equipment; ability to effect co-ordination of units with absolute flexibility in all departments; and—of *utmost importance*—our knowledge of cost where PRACTICABILITY ends and THEORY begins, enables us to differentiate between true and false economy.

Performing a Patriotic Duty

EVERY individual and every organization contributing toward those things which Our Country needs to strengthen her position and her effective power for war waging, is performing a patriotic duty, small or great.

Our contribution as an engineering organization is in the important work of supplying means of improving certain mine conditions, in order (1) to release men from non-productive labor and make them available for increased fuel production or for personal war activity, and (2) to speed up, directly and indirectly, the entire mine operation, thus increasing the fuel output.

The effect of the Pneumatic Rotary Dump is far-reaching. It not only reduces the labor and increases the speed of mine car loading, but also, by opening wider the outlet and removing causes of congestion in all channels of flow, increases the ease and rapidity of every movement, all the way from the extremities.

We offer you improvements and protection under Ramsay, Wood, Claghorn and other patents.

Garlock Air Compressor Packings

Are designed to withstand the extremely severe conditions under which air compressors usually are operated. Style No. 420 is composed of high pressure and compressor combination rings. The cushion center of the latter is covered by long fibre woven asbestos lubricated throughout with the celebrated Garlock compound. This packing does not harden in service, but retains its elasticity under the high temperatures and pressures met with in this class of work.

We manufacture a special packing, or combination of packings, for every class of service in coal mines. **Write for our new illustrated catalog.**

The Slogan of the Cameron—"Character: The Grandest Thing"

SMALL DETAILS BECOME BIG

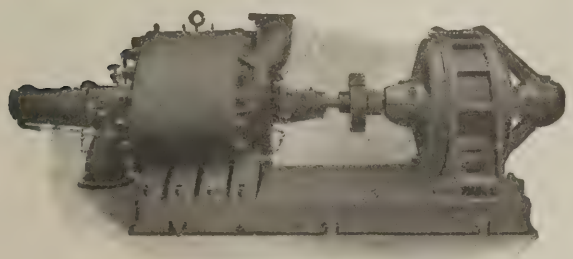
The smallest detail in a Pump becomes big and troublesome if it is skimped over in manufacture. The great point about

CAMERON CENTRIFUGALS

and why they last so long and have such low upkeeps is that every detail down to the smallest gets the greatest care in manufacture.

Examine the design and construction of the Cameron Class "DV" Centrifugal Pump, shown in the illustration. Note how every part is carefully finished to secure the greatest durability and efficiency.

Cameron Centrifugals make good on the hardest job as well as the easiest—and that's why they deserve your attention.



Get the Whole Story—Bulletin No. 7150.

MINE PUMPS

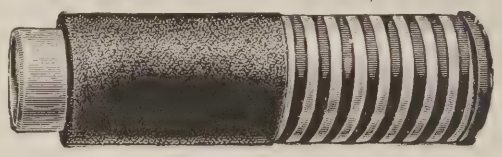
There's Satisfaction in an Ingersoll-Rand Mine Portable Compressor

In placing one of these self-contained units in your mine you can do so with the assurance that it is simple, sturdy, efficient and economical.

You obtain the advantage of Ingersoll-Rand Plate Valves—efficient, noiseless and long lived. Dirt and dust tight covers protect the wearing surfaces from grit. Motor drive through herring-bone gears running in an oil bath—compact and trouble proof. Automatic lubrication and self-control eliminate the need for constant attendance.

For the electrically equipped mine there is no better source of air power than these mine car mounted machines.

Shall we send you a full description? Ask for Bulletin 3015-1.



Ingersoll-Rand Company

WYCKOFF

WOOD PIPE

Instead of renewing your costly iron pipe—

Install Wyckoff Wood Pipe, the pipe that has been making good in mine service for the last half century.

Its faculty for resisting the action of sulphurous water is the reason for this—

Incidentally, it's the reason why Wyckoff Wood Pipe is in service in 90% of the Anthracite Mines and at least 60% of the Bituminous in the country.

So if you seek a pipe of proven durability, Wyckoff Wood pipe is that pipe—

As our engineers will prove to your satisfaction if you will take advantage of their cooperation.

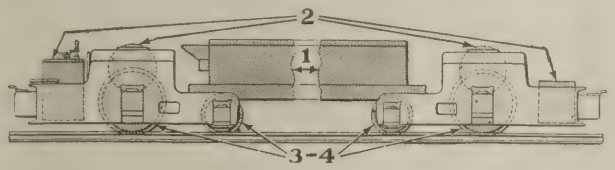
WHITCOMB
Gasoline Locomotives



The low cost locomotives. Low haulage costs are the result of many factors. Low costs constitute the barometer by which the true value of a locomotive can safely be determined.

Over 600 mines have measured the efficiency of the Whitcomb Gasoline Locomotive. The result is that over 600 mines are *using* the "Whitcomb"—the compact, powerful, safe and economical haulage unit.

Shall we show you what the "Whitcomb" will do for *your* haulage?

Geo. D. Whitcomb Company
Rochelle, Illinois

THIS outline drawing shows four vital advantages of the

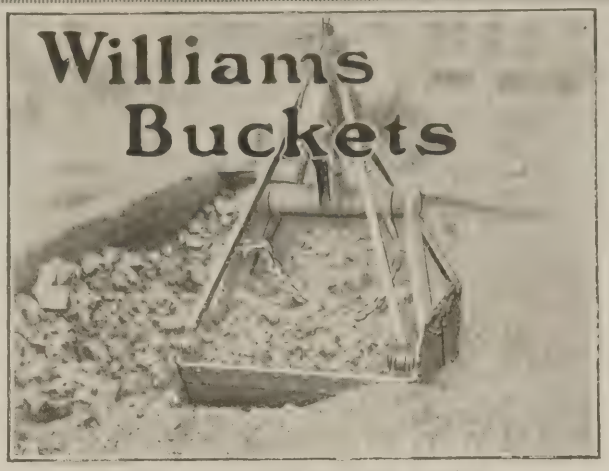
Goodman Articulated Storage Battery Locomotive

1—A storage battery of ample capacity may be accommodated between the bogy trucks.

2—One truck carries motor and controller; the other truck carries another motor and rheostat. Result—all mechanical parts are easily accessible and are located so they transmit no heat to battery.

3—The only running parts beneath battery are the idle wheels.

4—The weight is distributed onto eight wheels (not four). So the drivers are not forced to carry excess weight beyond what is necessary for desired draw-bar pull.



Many other exclusive merits that make the best of reasons why you should equip with Goodman Articulated Locomotives are given in Bulletin 522-A. **Write for it now.**

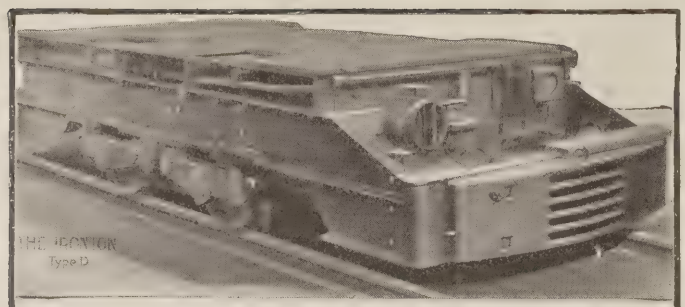
Mule Haulage Costs Cut Squarely in Half

THE Southern Connellsville Coke Co. used a PLYMOUTH Gasoline Locomotive for a year, keeping accurate cost records. Then they wrote us that it was doing *all* their work for *half* what they had formerly paid for horse-and-mule-haulage. Further, they say that their



PLYMOUTH
Gasoline Locomotive

runs on 5 gallons of gasoline and 1 quart lubricating oil per day; that it hauls 400 bushels to a trip, covering each hour 3 or 4 round trips of over 1½ miles each; that it works underground successfully and *does not throw off any objectionable fumes.*

Tell us about *your* hauling. Full particulars gladly sent.

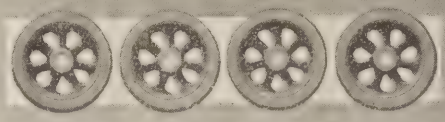
Let Your *Requirements* Be Your Guide

"In the choice of a storage battery locomotive care should be exercised in choosing: (1st.) The locomotive that meets your requirements; (2nd.) That it is equipped with a storage battery of proven merit." J. O. Durkee.

Ironton Storage Battery Locomotives are built in three types, one of which will meet **your** requirements. Each type is designed for known conditions and is equipped with a battery of proven merit. Standard in construction, but vary in size and battery capacity to meet the conditions for which each type is recommended.



THE IRONTON—Type D-1 FOR GATHERING AND CROSS ENTRY

Easy to handle in difficult places and in low coal. Only 32 inches high, it can be operated in any room where mining is practicable. Standard Ironton Features: Sturdy reinforced frame; Radial journal bearing housings; Independent chain drive to each axle makes each wheel a direct driver; Eccentric chain adjustment.

Send for Data sheet which will enable you to determine which Ironton will best meet your working conditions.

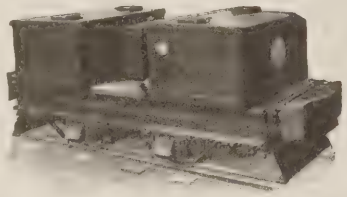
LOBDELL Chilled Iron Mining Locomotive Wheels

are backed by over eighty years of experience in wheel making. They are the most economical wheel that can be used for this severe service, having built into them by special processes of manufacture the ultimate of strength and wear.



Where increased traction is desired the Lobdell High Carbon Heat Treated Steel Wheel will be found the most efficient.

Send us the sizes of your locomotive wheels and axles so that we can quote you prices and deliveries that will interest you.

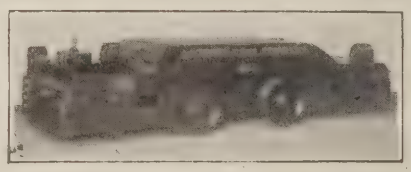
ATLAS
Storage Battery Locomotives



No. 5778. Storage Battery Mine Locomotive.

eliminate costly upkeep charges and are absolutely dependable.

Put your haulage problems up to Atlas Engineers. Write for your copy of "Cars and Electric Locomotives."

The Atlas Car and Manufacturing Co.
Dept. O, Ivanhoe Road, Cleveland, Ohio

IT costs $1.00 a day to feed the old mine mule, and Mancha's Electric Mule equals 6 to 10 of them.
It costs $1.00 a day to feed the MANCHA Electric MULE.

The old mine mule with his 1 M.P. (mule power) can pull a load of only 2 cars under certain conditions.
The MANCHA Electric MULE with its H. P. easily hauls a load of 8 cars under the same conditions.
How can your mine do its bit depending on the old mine mule?
Write for MANCHA FACTS and FIGURES.

ROLLER Bearing "Automobile" Cars

Whitney Roller-Bearing Wheels

Truck for cars now in use, or complete new cars, will be furnished equipped with the "Whitney" roller bearing wheels, with the floating automobile type of axle. Your cars will then run from six to twelve months with one greasing, will run with half the haulage power of the ordinary equipment. One man can push 12,000 lb. on a level track. Cars can run through water or sand without damage to bearings. In use in 1000 mines. All wearing parts, axles, spindles, rollers, wheels, etc., fully guaranteed. Largest coal mines using them.

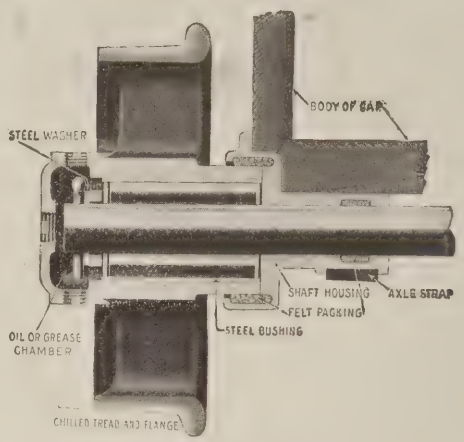
The Open Cap Truck

(Guaranteed)



IN this Truck are combined all the essentials that go to make up a first-class Mine Car Truck. It can be lubricated with either grease or oil with long service from each lubrication—is thoroughly dustproof—runs with very little friction—has a full-floating axle with visible linch pins which can be easily replaced, and is guaranteed against internal wear.

Selected by the Atlantic Refining Co. to demonstrate, at the American Mining Congress in Philadelphia, the highest development of a self-oiling wheel using their lubricant. We'll send you details.

Phillips Mine and Mill Supply Co.

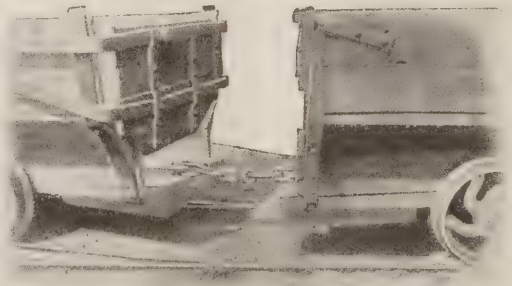
Your Mine Cars Need

OTTUMWA

Roller Bearing Car Wheels

They will run with less power and require less attention. Made of specially selected tough iron. Run on roller bearings that distribute the load and cut down the friction loss.

Let us quote you. Just state wheel diameter, weight of car loaded and distance center to center of axles. Write us now.



Ottumwa Iron Works, Inc.

Ottumwa, Iowa

The "Monarch" Car Hitching Eliminates Delay—and Hitches Up to Stay

When you hitch up your cars with "Monarch" car hitching you can rest assured that they won't come apart until you disconnect them.

With Monarch Hitchings you can handle more cars per day. Try them and see.

This hitching can be used on any size car and with any system of hauling.

It won't break because it is made of malleable iron with forged link and clevis. It is only 23 inches long.

Equip a few of your cars and give them a trial. You won't be sorry.

Coal Mine Railroads Use

Caldwell

Railroad Tank Fixtures

because they're the simplest, strongest and most satisfactory method of supplying locomotives with water.

Caldwell Railroad Tank Fixtures are a great improvement over the old style. They're considerably heavier than the usual fixtures and more durable. The spout is made of heavy galvanized steel and the outlet pipe of wrought iron. The outlet valve is also simple and strong in construction.

Built with the smallest number of small parts. Durable. Easy to erect.

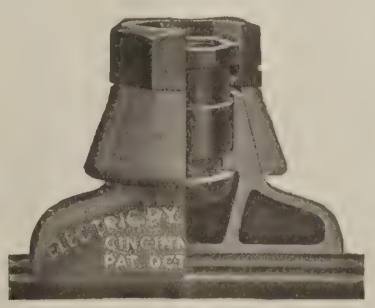
Canton Section Insulator and Switch

Simply Perfect It Is Perfectly Simple

"Perfect insulation when open—perfect contact when closed. Easy to adjust. Trolley wheel will pass even if switch is not thrown. Contacts renewable at slight expense."

Doesn't that sound just like what you want in a Section Insulator and Switch? Well, that's the Canton, **Shall we send you the full description?**



AMERICAN MINE DOOR CO., Canton, Ohio

"Sure Grip"

The sturdiest and simplest trolley clamp on the market.

Study the construction details shown in the picture and *know* the reason!

No need to explain its workings to a practical man.

Trolley Clamps

must have a viselike grip to give the required satisfaction.

More than 2,000,000 of these are in use today; ten years of practical testing stands behind them.

Coal Age Advertisers

!

Manufacturers of Coal Mine Equipment and Supplies

!

THE seventh "Annual Equipment Issue" of Coal Age which will be published on Saturday, July 20th, will be one of the most important numbers, both from an Editorial and Advertising view-point, that we have ever printed.

Be represented in the Advertising Section of this issue with a good-sized, up-to-the-minute advertisement.

Advertising forms for this Big Summer Special Number are now being arranged.

Send in your Advertising Copy Today.

PUT a patch on that tank

DON'T scrap that cracked engine bed

SAVE that cylinder head

Oxweld It

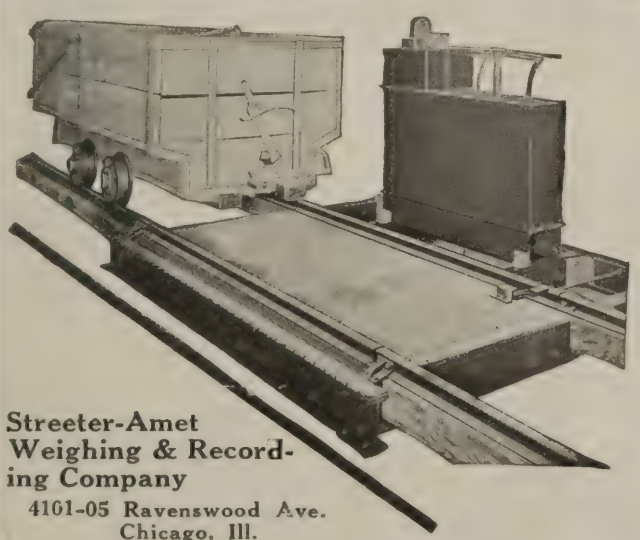
WHILE you have an Oxweld Injector Type Blowpipe on the job, these broken parts can be made like new. One emergency repair at your mine is likely to save in time and money more than ten times the cost of Oxweld equipment.

The Oxweld Injector Blowpipe is a necessity. It operates on the syphon principle. It works with equal efficiency on all pressures down to ½ lb. per square inch. It uses a larger proportion of the gas content of a cylinder than do the ordinary blowpipes.

We have a Bulletin that's mighty interesting
—let us send you a complimentary copy

Oxweld Acetylene Company

Newark, N. J. Chicago Los Angeles



World's Largest Maker of Oxy-Acetylene Equipment for Welding and Cutting Metals

The Streeter-Amet Weight Recorder

Don't Depend on a Man's Memory for Your Record of Tipple Weights

Get a mechanically accurate and permanent record of the weight of each car while in motion by installing the Streeter-Amet Recorder on your scale. It will pay for itself over and over. The cost of installation is trifling and if you don't care to purchase outright we will rent a Recorder to you at a low monthly rate.

Write today for full details, prices and terms.

Streeter-Amet Weighing & Recording Company

4101-05 Ravenswood Ave. Chicago, Ill.

Oxy-Acetylene Welding and Cutting Apparatus

OXY-ACETYLENE WELDING DAVIS APPARATUS DAVIS-BOURNONVILLE CO. N.Y.

HIGH GRADE WELDING SUPPLIES

Highest efficiency in results and greatest economy in operation. Both gases under independent pressure; positive mixtures; high pressure torch and neutral flame. Complete plants and extensive capacity.

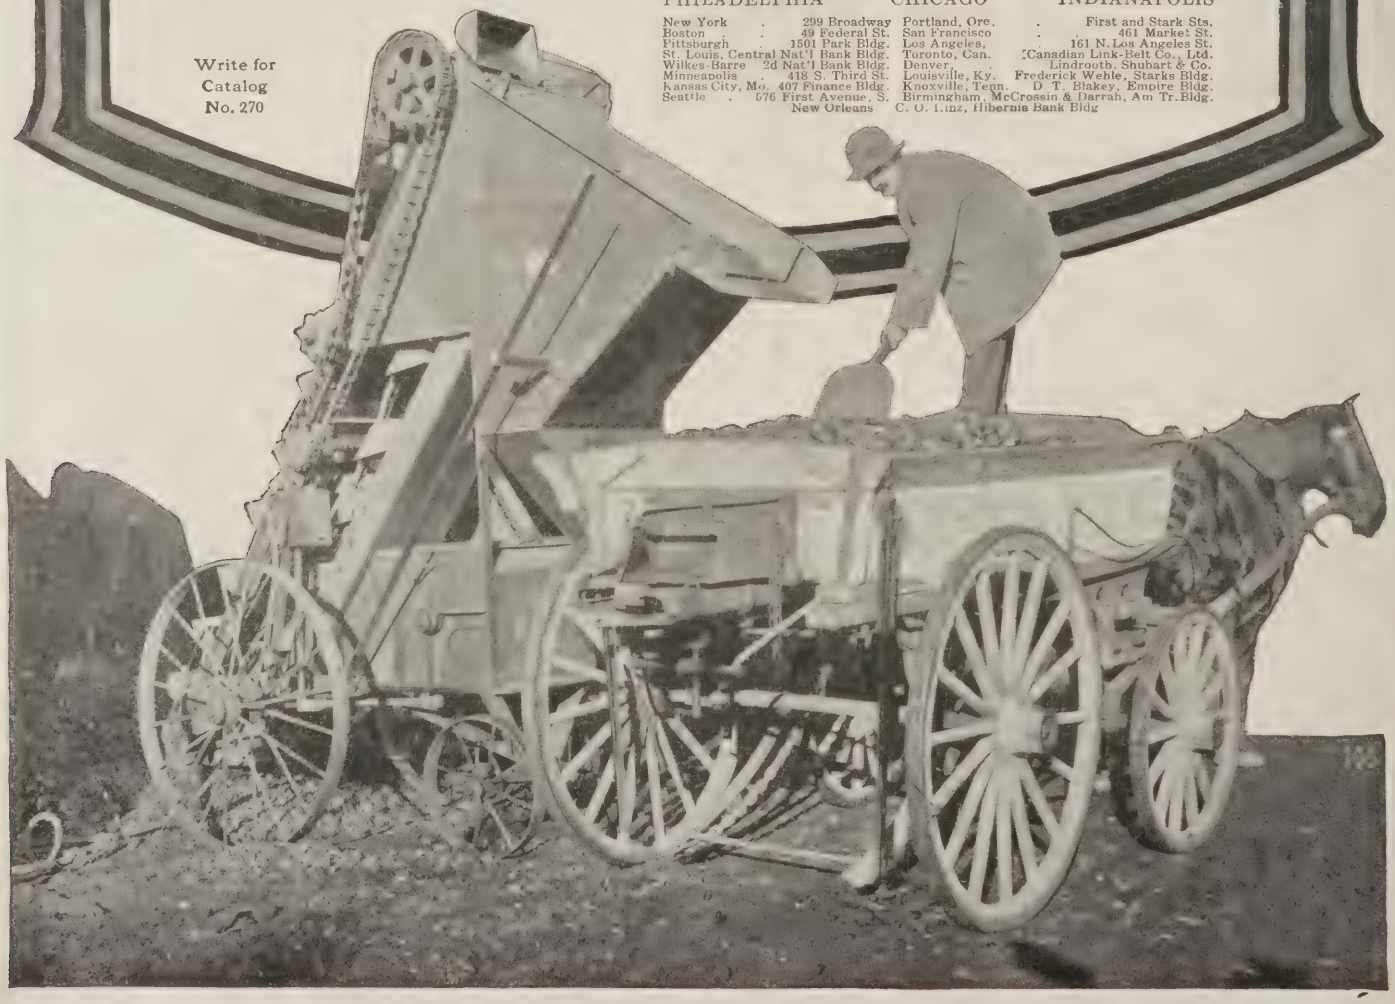
Don't Use Labor For This

THE work of shoveling any loose material into trucks, wagons, etc., can be done quicker, cheaper and better by machinery.

LINK-BELT
Wagon Loaders



can load one ton per minute. They are built for service and replace 5 to 10 men. The men today are needed for better work than shoveling. Do you employ men or machines for loading your material?

Write for Catalog No. 270
